Chemical & Metallurgical Engineering

A Weekly Technical Newspaper,
Being the Incorporation of
Electrochemical and Metallurgical Industry
and Iron and Steel Magazine

Volume XXII

From January 1 to June 30, 1920

436847
3. 7. 45

NEW YORK
McGRAW-HILL COMPANY, Inc.

INDEX TO VOLUME XXII

GENERAL ALPHABETICAL INDEX

PAGES

Jan.	7	1 to	48
Jan.	14	49 to	96
Jan.	21	97 to	144
Jan.	28	145 to	192
Feb.	4	193 to	240
Feb.	11	241 to	288
Feb.	18	289 to	336
Feb.	25	337 to	384
March	3	385 to	432
March	10	433 to	480
March	17	481 to	528
March	24	529 to	576
March	31	577 to	624
April	7	625 to	672
April	14	673 to	720
April	21	721 to	764
April	28	765 to	824
May	5	825 to	872
May	12	873 to	916
May	19	917 to	960
May	26	961 to	1008
June	2	1009 to	1052
June	9	1053 to	1096
June	16	1097 to	1140
June	23	1141 to	1184
June	30	1185 to	1224

A

Abrasive, Aluminous. Hutchins. (P.).. 1128
Abrasive, New aluminous. Hutchins..... *565
Absorption of gases in spray systems and towers. Baker..... *122
Absorption tower packing, Resistance to gas flow. Correction. Zeisberg.... 244
Acetaldehyde from ethylene by electrolytic oxidation. Curme. (P.)..... 40
Acetates from carbohydrates. Randall. (P)..... 1128
Acetic acid, From calcium carbide. Rooney *847
——From corn-cobs..... 407
——From ethylene by electrolytic oxidation. Curme. (P.)..... 40
Acetone by fermentation. Weizmann and Hamlyn. (P.)..... 662
——From acetic acid. Morton. (P.)..... 40
——From Burton still waste gases..... 407
——From calcium carbide. Rooney..... *847
Acetylene, Acetone from. Matheson. (N.) 710
——From hydrocarbons. Curme. (P.).. 40
——Solvent for. Smith and Curme. (P.) 708
Acid fumes on Riverside Drive. Mudge... 676
Acids, Pumping with compressed air. Oliphant..... *408
Acid-resisting materials:
——Acid resisting metals. Matignon. (S.) 376
——Cu-Al-Fe bronze. Kowalke..... 37
Adsorption, Theory of. Patrick. (N.).... 950
Air, Compressed, Pumping acid with. Oliphant..... *408
Air conditioning in the industries. Leason 279
Air conditioning prevents explosions ignited by static electricity..... 614
Air-lift system for pumping acids. Oliphant *408
Airplanes, Discharge of clouds from..... *407
Ajo, Arizona, Leaching operations at.... 388
Alaska, Committee urges pulp wood development..... 1176
Alaska-Gastineau Mining Co., Milling plant of. Daveler..... *361

ALCOHOL:
——As motor fuel. Tunison..... 297
——As motor fuel..... 952
——Dangers of denatured alcohol. Chute. 149
——From coal in England..... 487
——Industrial alcohol under the new law and regulations. Tunison..... 513
—— Changes in formulas. Tunison.... 1056
——Industrial alcohol. Rodebush. (N.). 665
——In patent medicines..... 1132
——Primary and secondary. Dehydrogenation by catalytic oxidation. Moureu and Mignonac. (S.)..... 1083
——Transportation regulation for denatured alchol in Texas..... 437
——Wood alcohol as beverage. Nolan.... 533
——Wood alcohol must be labeled poison 910
——Woodine..... 321
Alizarine cyanine, British mfr..... 1033
Alkalis. Caustic mixtures. Armstrong. (P.)..... 1174
——Industry in 1919..... 2
Alkaline earth chlorides. Schotoff. (B.P.) 1129
Allotropism among metals. Getman. (N.) 1000

ALLOYS:
——Acid-resisting Cu-Al-Fe bronze. Kowalke..... 37
——Duralumin in aëronautics..... 1125
——Electric-resistance. Schench. (P.).. 1085
——For feed water regulator floats. Mumford. (B.P.)..... 1129
——Iron-nickel, Magnetic properties of. Yensen. (S.)..... *1039
——Magnesium..... 61
——Melting point of, Determinations of.. *27
——Nickelene..... 1191
——Non-ferrous, Nomenclature..... 1191
——Tungsten..... 15
Aloxite, Hutchins..... *565
Alsace, Potash mines in..... 1206
Alsatian petroleum industry..... 1124
Alum, Chrome. Hultman. (B.P.)..... 1129
Alumina from labradorite..... 544
——Mfr. of Halvorsen. (P.)..... 812

ALUMINUM:
——Acid-resisting qualities of..... *230
——Aluminum rolling-mill practice. R. J. and M. B. Anderson
I. Commercial pig and scrap..... 489
II. Melting furnaces—Ingot pouring 545
III. Ingot heating and mill calculations..... 599
IV. Slabbing..... *647
V. Finishing operations..... *697
——As engineering material..... 298
——Norwegian industry..... 544
——Powdered or granulated. Terrets. (P.) 661
Aluminum alloys, Duralumin in aëronautics 1125
——Fatigue tests on. Gibson. (N.).... 1191
Aluminum chloride, Anhydrous. Heap and Newberg. (P.)..... 857
Aluminum nitride, Electric furnace for. Shoeld. (P.)..... *184
Alunite, Research on..... 713
Amalgamation plates, Steaming. Pearce and Thomas. (N.)..... 711
American Association for the Advancement of Science, Research grants..... 342
American Association of the Baking Industry..... 199
American Association of Engineers' convention..... 813

AMERICAN CERAMIC SOCIETY:
——Joint committee on ceramic research. 104
——Philadelphia meeting. Announcement 104
—— Report..... *438
——Chicago meeting. Program..... 1217

AMERICAN CHEMICAL SOCIETY:
——Spring meeting. St. Louis. Program. *534
—— Report..... *768
—— Industrial excursions..... *858

AMERICAN ELECTROCHEMICAL SOCIETY:
——Spring meeting. Boston. Announcement 245, 442
—— Program..... 533
—— Report..... *725
American Engineering Standards Committee 294
——New bodies represented on..... 1218
American Foundrymen's Association to have new department..... 861
American Gas Association meeting..... 1090
American Institute of Baking..... 396

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS:
——Spring meeting. Canada. Itinerary and program..... *1089
——Reversing in and out ratio of members. Olsen..... 676

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS:
——Annual meeting, New York:
—— Program 104, 245
—— Report..... *343
American Metal Co. buys L. Vogelstein & Co..... 55
American Pharmaceutical Association research grant..... 536
American-Scandinavian Foundation fellowships..... 485
American Smelting & Refining Co. report.. 908

AMERICAN SOCIETY FOR TESTING MATERIALS:
——Asbury Park meeting. Report 1189
American Zinc Institute:
——Annual meeting, Chicago..... 999

AMMONIA:
——Absorption of, In spray system..... *124
——Catalyst for oxidation of. Perley.... 125
——Oxidation of. Thomson. (P.)..... 1127
——Oxidation of. Toniolo. (B.P.)..... 1129
——Synthesis of. Claude. (P.)..... 812
——Synthetic, Heat interchanger for. Greenwood. (P.)..... *812
——Synthetic. Gardiner. (P.)..... 661
Ammonia saturator. Roberts. (P.)..... 948
Ammonium nitrate, Mfr. of. (P.)..... 857
——Mfr. of. Partington. (B.P.)..... 992
Ammonium perchlorate, Mfr. of. Wang. (B.P.)..... 1040
Ammonium sulphate, Caking of. Atwater and Schulze..... 373
——Cost of mfr. from oil shale..... 21
——From gypsum. (S.)..... 424
——Mfr. using sodium bisulphate. Vis. (P.)..... 904
——Purifying. Sloss. (P.)..... 662

ANALYSIS:
——Analytical control of electrolytic zinc production. Bradley..... *651
——Arc images in. Mott. (N.)..... 728
——Automatic gas-analysis apparatus for Government helium plants..... 832
——Carbon in iron. Yensen. (N.)..... 728
——Chlorbenzenes. Bourion. (S.)..... 1084
——Determination of graphitic carbon. Selvig and Ratliff. (N.)..... 726
——Determining active strength of sulphate cooking liquor..... 462
——Gas, Determining light oil in. Bird.. *705

ANALYSIS—*Continued:*
——Gas, Spark coil for explosion pipettes. Taylor..... 1013
——Gas wash-bottle for referee's test for sulphur. Maze..... *1070
——Iron: (see Iron and Steel, Analysis)
——Limitations of Ledebur method for oxygen in steel. Cain and Pettijohn. (S.)..... *375
——Moisture determination apparatus... *946
——Monel metal, Rapid method. Covitz.. 31
—— Comment. Horner..... 436
—— Comment. Stausser..... 1144
——Of coal pyrite for sulphur..... 106
——Power hammer for pulverizing pig-iron samples..... 946
——Tin in brass or bronze. Raymond... 1056
Annapolis, Prominent chemists lecture at. 342
Anthracene press-cake, Treatment of. Andrews. (P.)..... 569
Anthranilic acid, Precipitating from aqueous solution. Potter. (P.)..... 378
Anthraquinone by catalytic oxidation. Andrews. (P.)..... 378
Anthraquinone, Purification of. Andrews. (P.)..... 569
Antimony compounds, Proposed tariff on. 664
Antimony pigments. Morris. (B.P.)..... 1175
Apparatus, Meeting of makers of scientific 860
——Scientific, Imports of..... 756
——Standardization of. Freas. (N.)..... 775
Arc images in chemical analysis. Mott. (N.)..... 728
Arc phenomena. Steinmetz..... 458
Argentina, Wood pulp manufacture..... 1030
Arizona Copper Co. mill, Dust exhaust system at. Hull..... *207
Arizona Copper Co., Stack losses at. Ambler..... *305
Arsem vacuum furnace..... *67
Asbestos paper, History of. Bowles..... 208
Asphalt industry, Miller..... *749
Assaying, Volatilization in, Dewey. (N.). 347
——Same paper in full..... 797
Association of Scientific Apparatus Makers 860
Atmospheric Nitrogen Corporation..... 1131
Atomic structure of metals in solid solution. Comment. Jeffries..... 100
——Comment Smith..... 340
——Reply. Feild..... 580
Atoms, Structure of. Langmuir. (N.).. *486
Australia, Electric steel furnaces in. (S.) 947
——Flax industry..... 988
——Foreign trade, 1918-1919..... 881
——Marking of imported goods..... 540
——Production of tin in. Lewis. (S.).. 903
Austrian engineers, Aid for..... 906
Auto-electrolysis..... 966

B

Babbitt: (see Bearing metal.)
Baking industry, Chemical engineer in. Lippert..... *893
Baking industry to be studied..... 199
Barium hydroxide from barium sulphide. Barnes. (P.)..... 89
Barium nitrate from barium sulphide. Davis. (P.)..... 378

BATTERIES:
——Primary:
—— Reserve dry cell. Batchelor. (P.). 856
——Secondary:
—— Reactions of lead accumulator. MacInnes. (N.)..... 727
—— Separators for. Rowson. (Aust.P.) 522
Bearing metal, Crystal growth in. Mahin. (N.)..... 775

BELGIUM:
——Artificial silk industry, Prosperity of 1144
——Industries one year after the armistice 645
——Penalties for commercial fraud..... 892
——Plate and window glass industry.... 487
——Steel cartel, Dissolution of..... 976
——Sugar production..... 1188
Belting, Leather, Measuring slip..... 255
Belt joining, Improved method..... 566
Benzaldehyde from toluene by catalytic oxidation. Weiss and Downs. (P.).. 522
Benzene, Catalytic oxidation of. Weiss. (N.)..... 102
Benzoic acid from toluene. Coblentz and Walker. (P.)..... 812

BIBLIOGRAPHIES:
——Nitrogen fixation..... 588
——Tungsten..... 16
Bismuth, Darling. (P.)..... 377
Bisulphite liquor manufacture. Baker. (N.)..... 781
Black ash, Extracting soda salts. Vrastel. (N.)..... 781
Black liquor from sulphate pulp, Treating. Olsson. (P.)..... 378
Blast-furnace: (see also Iron and Steel, Furnaces.)
Blast furnace, Comparative study of electrically and coke heated. Guédras. (S.)..... 990
Blast-furnace top, Rust. (P.)..... *377
Blast roasting at Port Pirie. Rigg..... 518
Bleaching powder, Mfr. of. Rudge. (P.).. 857
Bleaching with ozone..... 806

*Illustrated; (P.), (B. P.), (Aust. P.), (Can. P.)—United States, British, Australian and Canadian patents, respectively; (S)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

Bohemian glass industry 464
Bolivian petroleum deposits purchased... 910
Book Reviews....42, 185, 282, 331, 474, 570, 667, 817, 910, 1001, 1047, 1090

BOOK REVIEWS:
——Andros. The Petroleum Handbook... 817
——Classen. Quantitative Analysis by Electrolysis 185
——Darling. Inorganic Chemical Synonyms 667
——Davy and Farnham. Microscopic Determination of Ore Minerals 910
——Franke. A Handbook of Briquetting. 283
——Hatfield. Cast Iron in the Light of Recent Research..... 1001
——Hendricks' Commercial Register of the United States for Buyers and Sellers 474
——Hoyt. Metallography. Part I..... 1090
——Mahin. Quantitative Analysis..... 570
——Rideal. Industrial Electrometallurgy, Including Electrolytic and Electrothermal Processes..... 42
——Schenck. The Physical Chemistry of the Metals 1047
——Scott. The Journal of the Institute of Metals 474
——Slosson. Creative Chemistry 185
——Smith. James Cutbush, an American Chemist 283
——Twyford. Storing, Its Economic Aspects and Proper Methods..... 331
——VanKlooster. Lecture Demonstrations in Physical Chemistry 282
——Wein. Selenium Cells and How They Are Made 331
——Winslow and Pratt. Sewage Disposal 474
——Problems of Labor and Industry in Great Britain, France and Italy.... 185
Booth rotating furnace, Foundry test of.. 136
Borax in fertilizers..... 462
Bottle-blowing machine..... 859
Box-making course at Forest Products Laboratory 268
Box-testing machine, Drum..... *1126
Braden, Power development. Thomas. (N.) 101

BRASS:
——Booth rotating furnace vs. gas fired crucible for melting..... 136
——Determination of tin in. Raymond.. 1056
——Electric furnace, Evolution of. St. John. (N.)..... 733
——Heat treatment of beta brasses. Brayton *211
——Influence of cadmium on. Guillet. (S.) 947
——Naval, Physical properties, Campbell. (N.) 1191

BRIQUETTING:
——Experimental plant. Stillman..... *1035
——Mold for refractories..... *66
——Zinc ore..... *75
Brazil, Laboratory facilities for analysis of imports 754
Bread, Industrial research on..... 251
Brine corrosion of petroleum equipment. Mathews and Crosby..... 491
British: (see under England.)
British Chemical Industry....56, 200, 389, 628, 828, 1013

BRONZE:
——Cu-Al-Fe, Acid-resisting alloy. Kowalke 37
——Determination of tin in. Raymond.. 1056
——Elastic properties of bronze castings. Comstock *1113
Bronze plating. Mathers and Sowder. (N.) 728
Bronze powder industry in Japan..... 734
Brooklyn Polytechnic Institute, Annual alumni banquet of Chemical Society 1001
Bucher process, Improvement of. Mont. (P.) 709
Buenos Aires, Exposition of United States manufacturers in.....688, 713
——National hydraulic laboratory..... 1075
Budget bill..... 952
——Rejected 1132

BUREAU OF CHEMISTRY:
——Appropriation 448, 535
——Color laboratory. Gibbs..... *405

BUREAU OF MINES:
——Cottrell succeeds Manning as director *884
——Cryogenic laboratory to be established 1086
——Non-metals experiment station..... 1046
——Proposed consolidation with Geological Survey 952
——Tunnel ventilation problems..... 295

BUREAU OF STANDARDS:
——Appropriation 815
——Current activities of the stations.... 542
——Enamel investigations 810
——Plans increase in chemical activities. 56
——Standard samples. Comment. A.A.N. 964
——Standard samples, Present status of. 1047
Burma Corporation, Ltd., Report..... 197
Burns, Sag paste for..... 592
Business side of chemistry. Eisenschiml.. 53
Butyl alcohol by fermentation. Weizmann and Hamlyn 662

C

Cadmium, Influence on brass. Guillet. (S.) 947
Cadmium solder. Luckey. (P.)..... 1040
Caking of salts. Lowry and Hemmings. (N.) 976
Calcium arsenate insecticides..... 254
Calcium carbide and wood distillation products. Reid. (P.)..... 661
Calcium, Electrolytic production. Brace. (N.) 728
Calcium fluoride, Mfr. of. Chase. (P.)... 662
Calcium molybdate as an addition agent in steel making. Kissock..... 1018
Caliche deposits 656
California Fruit Growers Exchange research laboratory 876
California Institute of Technology..... 500
California, Power development in..... 876
California Section, A.C.S:
——February meeting..... 437
——March meeting..... 665
Calumet & Arizona Mining Co. report.... 908
Camphor from isoborneol. Andreau. (P.) 616
Camphor production in British Empire... 1030

CANADA:
——American glass in..... 423
——Chemical exports..... 210
——Exhibition in France..... 496
——Foreign trade for 1919..... 850
——Large chemical company organized.. 907
——Mineral production for 1919. (S.).. 855
——Productive power..... 975
——Pulp and paper combination formed.. 1176
——Pulp wood embargo may cause retaliation 1044
——Research bureau to be established.. 1046
——Special overseas trade commission... 902
——Ten commandments for trade..... 862
——Water-power development 1200
Canadian Institution of Chemistry..... 815
Carbazol, Purification of. (B. P.)..... 1216
Carbo-hydrogen gas. Rose. (P.)..... 1128
Carbon, Determining graphitic carbon. Selvig and Ratliff. (N.)..... 726
——In furnace refuse, Loss due to. Berry *179
Carbon black, Testing natural gas for. Neal *358
Carbon monoxide detector..... 906
Carborundum, Increasing uniformity of. Hutchins. (P.) 709
Carborundum refractories to be made at Perth Amboy 907
Carnegie Corporation aids National Academy of Sciences and National Research Council 198
Castner caustic soda-chlorine cell..... *206
Castor oil plant at Gainesville. Shrader and Goetz *833
Catalysis, Contact. Bancroft. (N.)..... 725
——Practical applications of. Bray. (N.) 437
——Theory and practice of..... 102
Catalyst for oxidation of ammonia. Perley 125
Catalysts for hydrogenation. Brochet. (B.P.) 948
Catalyzers in paint and varnish manufacture. Ingalls..... 590
Cat-tail as source of food..... 420
Caustic pot settings. Wheeler..... 373
Ceco spray system *174
Cellulose acetates. Zdanowitch. (B.P.).. 1175
Cellulose chemistry, Plea for scientific study of. Hibbert..... 838
Cellulose compounds. (B.P.)..... 1129
Cellulose ester solutions. Carlsson and Thall. (B.P.)..... 992
Cellulose symposium. Correction. Cohoe.. 244
Cellulose symposium, A.C.S. meeting..... 932

CEMENT:
——Electric drive in Victorville mill.... *292
——From low-grade carboniferous material. Lesley. (P.)..... 709
——Mfr. in electric furnace. Boillot and Daudignac. (P.) 708
——Olympic Portland Cement Co. plant.. 196
Cement drain tile, Durability in alkali soils 366
Central Foundry & Supply Co. at Nitro... 342

CERAMICS:
——Ceramic building for Rutgers College. Millen 410
——Ceramic processes and colloid phenomena. Bleininger. (N.)..... 779
——Commercial pottery of Japan..... 702
——Developments during 1919..... 4
——Feldspar as pottery material. Staley. (N.) 54
——Laclede-Christy Co. plant..... 858
——Properties of pottery bodies and glazes. Schurecht. (N.)..... 55
——Short course at Univ. of Illinois..... 864
Chamber of Commerce, New International 864
Chandler, Dr. Charles F., Receives Perkin Medal 103
——Full report of presentation..... *150
Chandler medal, Dr. Whitney to receive.. 666
——Presentation 863
Charcoal from walnut shells..... 1045

CHARTS:
——Alignment:
—— Loss due to carbon in furnace refuse. Berry *179
—— Vapor pressure-temperature relation for liquids. Savage..... *1155
——Viscosities in different systems. Nevitt *1171
Chemical and physical constants, Compendium of..... 247
Chemical engineer in baking industry. Lippert *893
Chemical engineering at Columbia University. Hendrick *162
Chemical engineering at University of Nebraska 665
Chemical engineers, Lessons for, In other industries. Marshall 218
Chemical Engineers, Reversing in and out ratio. Olsen 676
Chemical Foundation, German opinion of. 348

CHEMICAL INDUSTRY:
——Electrochemical industry in Scandinavia 1082
——Electrochemical industries in Sweden. Beckman 840
——Exposition of: (See National Exposition of Chemical Industries.)

CHEMICAL INDUSTRY—*Continued:*
——French, Development of..... 975
——In Holland..... 654
——In Sweden..... 464
—— Comment. Huitman 920
——In 1919..... 1
——Italian, Development of..... 791
——Need of co-operative educational work in. Cohen 509
—— Comment. Burr 724
——Of Southern States. Fairlie..... *307
—— Comment. Maher..... 724
Chemical market...44, 91, 141, 188, 236, 285, 332, 379, 426, 476, 524, 572, 619, 669, 716, 759, 819, 867, 912, 955, 1003, 1048, 1092, 1135, 1179, 1219
Chemical warfare. Fries. (N.)..... 773

CHEMICAL WARFARE SERVICE:
——Annual dinner *55
——Army reorganization bill reported to Senate 245
——Becomes a separate service..... 663
——Continues 1132
——General Sibert and. Wooton..... *755
——On peace basis 1217
——Progress of Army reorganization bill. 199
——Recruiting stopped..... 665
——Vocational school of 865
Chemistry for undertakers. Seyt..... 484
Chemists, Classification and salaries of. McBride *689
Chemists' Club elects officers..... 998
Chemists' Club will purchase German marks 508
Chemists' salaries, Government..... 488
Chestnut stumpage for sale..... 816
Chicago Chemists' Club..... 861
——Annual meeting 999
——Weekly luncheon inaugurated..... 1131
Chicago, John Crerar Library moves..... 1043
Chicago section, Amer. Ceramic Soc.:
——April meeting..... 861
——May meeting. Enameling..... 1107
Chicago section, A.C.S.:
——December (1919) meeting..... 53
——January meeting. Tungsten..... 248
——May meeting. Willard Gibbs medal.. 1086
Chicle gum in British Guiana..... 1017
Chilean nitrate, Ample supply assured.... 448
——Industry. Bertrand..... *655
—— Economic aspects..... 1207
——Output and shipments..... 1032
China, Awakened industrial..... 754
——Peanut and peanut oil exports..... 1173
——Rubber tires in..... 405
Chlorbenzenes, Analysis of. Bourion. (S.) 1084
Chlorhydrins from oil gas. Brooks..... *629
Chloride volatilization experiments at Eureka, Utah..... 52
Chloridization tests 879
Chlorination of aromatic compounds. Morris (B.P.) 1175
Chlorination, Vapor phase 406

CHLORINE:
——Chlorine's place in our daily life.... 509
——Electrolytic cell, McDorman. (P.).. *1216
——Liquefaction of. Henderson. (P.).. 1128
Chlorpicrin, Mfr. of. King. (P.)..... 661
Chrome alum. Hultman. (B.P.)..... 1129
Chromium, Electrolytic. Sargent. (N.).. 728
Chromium-nickel alloys. Gatward. (S.).. 661
——Comment. Fairchild 1144
Chromium sulphate, Mfr. of. Mooney. (P.) 857
Chuquicamata, Power development at. Thomas. (N.) 101
Cibucao wood for dye in Hongkong..... 888
Citric acid, Mfr. of. (B.P.)..... 1040
Civic Forum Medal awarded to Hoover .. 341
Civil Service examinations 247, 342, 437, 666, 816, 1090
Classification and salaries for chemists. McBride *689
Classification for chemical, physicochemical and physical phenomena 103
Clay, Colloidal, in soap. Weston. (S.) . 615
Clay, Classification, testing, storing and handling, etc. (N.) *439
Cleveland Section, A.C.S.:
——March meeting 665

COAL:
——Carbonization of Missouri cannel coal. Dunlap and Kershner. (N.) 774
——Low-temperature carbonization in England 692
——Powdered, In chemical and allied industries. Fitch. (S.) 183
——Pulverized, Explosion hazard in steel mills due to partly consumed 422
——Pulverizing plant at Nevada Consolidated Smelter. Pomeroy. (N.) .. 347
Coal ash from Eastern coals, Fusibility of. Selvig, Brown and Fieldner..... 80
Coal briquets, Mfr. at Swansea 1134
Coal pyrite, Chemical data on. Yancey... *105
Coal storage, Scoop conveyors for..... *182
Coal tar for fuel. Church. (N.) 296
Coal tar, Utilization of. Sharples. (S.).. *903
Cobalt, Recovering. Udy. (P.) 1174
Cobalt oxide, Use in ceramics. Davis. (N.) 439
Cobalt silver ore, Smelting and refining. Wright. (S.) 855
Coke plant at La Belle, Blackiston *561
Coke ovens, Robert type, at St. Louis Coke and Chemical Co..... 907
College of City of New York to give engineering degrees 860
Collinsville Zinc Corp., Lithopone plant. Jones *497
Colloidal clay soap. Weston. (S.)..... 615
Colloid symposium, A.C.S. meeting (N.) 778
Colloid symposium. Bancroft. (N.) 726
Colloid theory applied to asphalt 753
Colorado, Resources of 1100

*Illustrated; (P.), (B. P.), (Aust. P.), (Can. P.)—United States, British, Australian and Canadian patents, respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

Colorimeter for white paints..... 1192
Color laboratory, Bureau of Chemistry. Gibbs *405
Columbia University, Teaching chemical engineering in. Hendrick *162
Commercial organizations in the United States 711
Concentrating solutions, Process of. Walker. (P.) 709
Concrete, Test of water storage tanks .. 696
Condenser tubes, Corrosion of. Bengough, Jones and Pirret. (S.) 707
Constants, Compendium of chemical and physical 247
Construction and operation, 47, 95, 144, 192, 239, 288, 336, 383, 431, 479, 528, 575, 623, 672, 719, 763, 822, 871, 915, 959, 1006, 1052, 1095, 1139, 1183, 1224.
Contacts, Tungsten, Mfr. of 13
Converter and electric furnace. Sarron and Simon. (P.) 233
Conveyors, Pneumatic, At Aluminum Co. plant *566
Cooling liquids in spray systems and cooling towers. Baker *173
Co-operation during reconstruction 734
Co-operative associations Cohen 509

COPPER:

——And magnetite in copper smelter slags. Maier and Van Arsdale. I *1101
II. *1157
——Cost of production in 1918 38
——Hydrometallurgy and pyrometallurgy, 1919 6
——Hydrometallurgy of. Lyon. (N.) 1178
——Intercrystalline brittleness. Rawdon and Langdon. (N.) 346
——Operations at Ajo 388
——Precipitating from hot solutions. Laist. (P.) *1041
——Precipitating prior to flotation. Sulman and Picard. (P.) 991
——Precipitation on charcoal. Fleming. (Aust. P.) 904
——Production from secondary material. Addicks *119
——Relationship of chemical and physical properties of. Antisell. (N.) ... 344
——Requirements of refined copper. Addicks *449
Copper ores, Hydrometallurgical process for. Greenawalt. (P.) *473
Copper ores, Lixiviation with SO_2 solution. Christensen. (P.) 184
Copper-lead ores, Smelting. Johnson. (P.) 991
Cotton linters, Pulp from. Kress. (N.) 781
Cotton seed and cottonseed products. .906, 1081
Cottonseed mills import peanuts 1045
Cottonseed oil industry, Pictorial description of. Wesson *465
Cottrell receives Willard Gibbs medal.... 1086
Cottrell succeeds Manning as Director, Bureau of Mines *884

COTTRELL PRECIPITATOR:

——In Japan. Hirota and Shiga *276
——Motion of droplets and particles in field of corona discharge. Tolman and Karrer *1203
——Recovery of potash. Bradley. (N.) 756
Corona discharge, Motion of droplets and particles in field of. Tolman and Karrer *1203
Corporation patriotism 306
Corrosion: (see Metal protection and corrosion.)
Crescent belt fasteners 566
Crown-Willamette Paper Co. installs Jennsen system 1176

CRUCIBLES:

——For melting point determinations ..25, *66
——Graphite for 220
——Tungsten. Keyes. (P.) 184
Current Events 663, 710, 756, 813, 861, 905, 949, 993, 1042, 1086, 1131, 1176, 1217.
Cyanamide, Cyanides from. Landis 265
Cyanamide furnaces, Strawboard lining for. Middleton. (P.) 89

CYANIDES:

——From calcium carbide. Jacobs. (P.) 474
——Manufacture from cyanamide. Landis 265
——Manufacture, Review of developments in. Philipp 313
——Production of. Clancy. (P.) 856
——Production of. Lindblad. (P.) ... 617
——Production of. Mount. (P.) 709
Cymene sulphonic acids. Amber, Lubs and Gibbs. (P.) 42

D

Defects in steel: (see Iron and Steel, Defects.)
Dental cements, Development of..... 253
Denver, Industrial research at..... 1086

DETINNING PROCESSES:

——Electrolytic. Elkune. (B. P.) 1129
——Electrolytic. Tatro and Delius. (P.). 41
——Ferric salt process. Rumbold. (B. P.) 424
Detroit Engineering Society meeting..... 950
Diatomaceous earth, Phalen 981
Differential method for melting point.... *28
Dimethyl sulphate mfr. Durrans. (P.).. 41
Dinitrochlorbenzene, Mfr. of. Heyden. (P.) 709
Diphenyl from benzene 102
Dracco system at Armour Fertilizer Co... *182
Drain tile, Cement, Durability in alkali soils 366
Driers, Paint: (See Paint)
Dry cells: (see Batteries, Primary)
Dust exhaust system at Arizona Copper Co. mill, Hull *207
Dust hazard at Niagara Falls plants, Elimination of 348

DYE BILL:

——Licensing system, Controversy over... 101
——Substitute for dye licensing system.. 248
——Dye bill ready for Senate 294
——Senate debate on dye bill 390
——Moses amendment 584
——A. C. S. resolution in favor of Longworth bill 770
——Before Senate 905
——Fate of dyestuffs bill 951
——Moses automatic tariff amendment.. 998

DYES:

——British, Finer colors lacking 909
——Cibucao wood used in Hongkong.... 888
——Dye industry in Great Britain 535
——Dye section, A. C. S., Plans..... 390
—— Meeting. (N.) 776
——From halogenated hydroxynaphthoquinones. Wheeler. (P.)..... 569
——German, Allocation of 1218
——German dyes imported 1088
——German, Scarcity of 909
——Hongkong excludes American dyes.. 1133
——Production costs in dye industry.... 488
——Purple dye from shellfish..... 906
——Swiss dyes received..... 1133
Dyestuff industry, Dangers in. Cone 33

E

Earth's crust Chemistry of. Washington. (N.) 665

PRODUCTION STATISTICS:

——Canada:
—— Minerals, 1919 .. 855
——England:
—— Iron and steel, 1919 .. 744
——Italy:
—— Chemicals, 1914 and 1918 .. 791
——Mexico:
—— Metals, 1916-1919 .. 782
——Sweden:
—— Copper, 1918 .. 792
——United States:
—— Ammonium sulphate, 1902-1918. *903
—— Beet sugar, 1913-1920 .. 560
—— Copper, 1913-1918 .. 38
—— Cottonseed products .. 1081
—— Gold and silver, 1919 .. 217
—— Mercury, 1919 .. 989
—— Nitrogen compounds, 1900-1918 .. 444
—— Peat, 1908-1918 .. 693
—— Petroleum products .. 504
—— Phosphate rock 1913-1917 .. 308
——World:
—— Coal, 1910-1919 .. 1020
—— Glycerine, 1884-1917 .. 226
—— Nitrogen compounds, 1900-1918 .. 444
—— Sugar, Beet and cane 1916-1919 .. 312
—— Beet .. 560
Propylene chlorhydrin from oil gas, Brooks .. *629

A Survey of The Chemical Industry

THE chemical industry, as always, is in a state of transition. Roughly speaking, five years ago one would say that the chemical industry required about two dollars of capital invested for every dollar of annual turnover. Now capital requirements are almost doubled for the same turnover. Disregarding war contracts, which were largely made and enjoyed by men who are not ordinarily manufacturers of heavy chemicals, it is doubtful if any other essential industry has maintained so level a curve of prices as this.

The war has not produced new developments in chemical war materials, except, perhaps, in regard to sulphur. New sources chiefly in Texas promise cheaper sulphur, and for the first time in many years the element has been widely used in the place of pyrite and other metallic sulphides in the production of sulphuric acid. This, however, was rather due to shortage of iron pyrites than to competitive prices. It remains to be seen whether the sulphur producers can or will adjust their prices to compete with those ores under future normal conditions.

Muriatic, nitric and acetic acids were all used in very large quantities during the war, but the war did not perfect or revolutionize any process for them in this country.

Practically all the war plants built under Government auspices are closed. They were not planned for industrial use, and many of them unfortunately were not even happily designed for industrial advantage. Whether these plants can ever work themselves out of the category of junk aggregates is a serious question. At present they are incomplete and idle or in process of dismantling, and their prospects are not rosy.

No official effort has been made in this country toward the unification of chemical industry during or since the war, although in England there has been a marked tendency in this direction. In Germany all of their war developments were laid out with a view to improving the condition and co-ordination of chemical industries after the war. There is a curious psychology in this. Nobody enjoys making a dollar more than the typical American, but nobody cares so little for it after it is made or is less anxious to keep it than he. At the same time, if anyone has the courage to venture his wealth in an enterprise that has been organized by the Government, and succeeds in his venture, suspicion is immediately aroused. His profits are resented, and the officials of the Government who planned for just such industrial success are condemned. So it is fair to say that our Government has given substantially no consideration to permanent industrial development, and that the people of the country will therefore receive no benefits from it.

The Germans in the past have gone ahead faster than we have. This is not due to better chemists; it comes rather from better chemical understanding in high places, and greater concentration of resources.

Chemical research in the U. S. A. during the war period has been confined largely to the organic field, and since Germany was in control of a great part of that industry, it has consisted principally in trying to follow Germany. Otherwise the war has hindered rather than promoted true research.

As to markets and plant operations, the tremendous momentum of production at the time of the Armistice in November, 1918, was arrested by February, 1919, and in March and April of that year trade was very dull. By May and June it had picked up, and now everybody is busy. This is more than can be said of England and France, where, in neither country, are the peace plants operating at full load.

Industrial chemistry has made a big forward stride during the past year, not so much through the development of new processes or through any remarkable improvement of established processes, but rather through a silent and unspectacular invasion of industries that have heretofore gotten along with but little assistance from the chemist or without an intensive application of the principles of chemical engineering. There has also been evidenced an extension and broadening of the scope of the work performed by the chemist and physicist in chemically controlled industries and an added importance placed upon the technical positions in industrial organizations. Thus we note an expansion of the personnel of research departments and an extension of their investigations to cover the whole field of industrial activity, and also find the chemist employed in the smaller plants as an addition to the operating staff.

That this should take place during a year in which industry as a whole has marked time awaiting a more favorable opportunity for expansion and development augurs well for the future position of the industrial chemist and of the chemical industries.

Electrometallurgy In 1919 and Afterward

THE year just passed was an active one for the electrometallurgical industries. The beginnings of large improvements were numerous and important. In fact, one feels that the electrometallurgical processes are "coming into their own."

In the iron and steel industry the introduction of electric melting and refining furnaces in steel plants was more active than ever before. This industry has already far outstripped the crucible steel process, and if it was not so well fitted to work duplex or triplex with the bessemer converter or open-hearth furnace, or both, we might say that it was a potential successor to these

standard steel apparatuses. Works experience with the electric steel furnace is certainly short and limited in comparison with other processes, yet it is the most rapidly developing improvement in the whole steel industry.

In Scandinavia the electric reduction of iron ores to pig iron is on a sound commercial basis, and large extensions are already under way, such as at Lulea, where six of the largest size (2500 kw.) furnaces are being erected. It looks as if the knell of the iron blast furnace is about to sound in Sweden, and the situation is likely to spread to other countries similarly situated as to power and fuel cost.

The electrolytic refining of iron, for the commercial production of very pure iron, made its commercial début in France in 1919. Details are not yet published, but the plant is invaluable for producing the basic material for the highest quality of special alloy steels.

The synthetic production of cast iron of carefully controlled quality from the superabundance of steel scrap from munition machine shops was a war development in which electric furnaces were the necessary apparatus. A description of several fine plants erected for this purpose in France has just been distributed by the American Electrochemical Society, written by the chief director of this industry in France, CHARLES A. KELLER. How much of this industry will survive under post-war conditions is not certain; we believe that a considerable part of it is bound to survive as a stable industry.

Automatic heating, hardening and tempering furnaces electrically heated and controlled have attracted great attention in the past year. The leading American designer and constructor of these apparatuses has rapidly devised one type of furnace after another, designed to replace the trained and experienced workman by the impeccable machine with its superhuman electric control, and served by a common laborer. The steel industry stands to benefit largely in the near future from these innovations, and other metal industries will likewise share the advantages of these electrical improvements.

In the non-ferrous metal industries 1919 was characterized by the rapid introduction of electric melting furnaces in place of melting in crucibles or open-combustion furnaces. Crucibles cost twice as much and are not half as lasting as they once were; the electric furnace had a great opportunity, and it was grasped. It is hardly conceivable that the industry can or will back-track. Fifty or more electric furnaces were erected in a single brass-producing city (Bridgeport, Conn.), and all the other brass makers in the country are either looking on with interest or have determined to follow suit. America is leading the world in this development, and the brass and other related industries of other countries cannot do otherwise than imitate our methods and follow our lead.

Altogether, just from this fragmentary review of what is only a part and not the whole field of electrometallurgy, the advocates of this branch of science and industry must feel proud of the rapid progress made and the innovations introduced in 1919. It is only a fraction of the progress which will be recorded in this line for this year, for the door is just opening, and the general introduction of electrometallurgical methods bids fair to work revolutions in many of the metal industries in 1920.

The Alkali Industry During the Past Year

IN REGARD to alkalis there is substantially nothing new in technology. Before the war $12 a ton was a more or less standard price for soda ash, and Europe could not compete with domestic manufacture in this territory. Now labor and steam power have become very uncertain factors both here and abroad, but it hardly seems likely that we need fear foreign competition in the home market for soda. Business in soda ash and caustic has been very similar to that of sulphuric acid: great demand during the war, followed by a heavy slump after the Armistice, and now plants are running nearly to capacity again. It should be remembered that many big caustic plants have lately doubled and some even trebled their capacity, but in spite of that they are running nearly full time.

This is partly explained by exports to the Scandinavian countries, which are the natural customers of Germany; to South America, formerly supplied by England and Germany; and to France and Spain and elsewhere. These markets have been obtained by American producers, not by low prices or cheap production, but because there has been no competition. Germany does not seem to have soda for export as yet, which may be due to labor troubles, or coal shortage, or to difficulties in transportation. The same may be said of England, so that when European manufacturers start to go after that trade, to get back what was formerly theirs, it may be that production will have to be curtailed. It will be largely a question of manufacturing costs.

There is considerable talk of a combination of the Haber process for making ammonia with the Solvay process in Europe. For the Solvay process it will be recalled that brine, ammonia and limestone are needed, and by this combination of processes the ammonia would come direct from the Haber plant, enter with CO_2 and water as ammonium bicarbonate into reaction with salt in which acid radicals are exchanged. Then sodium bicarbonate precipitates from the ammonium chloride solution, and this liquor, on treatment with caustic lime, sets the ammonia free. The ammonia may then be treated with sulphuric acid to form ammonium sulphate and sold as fertilizer.

We fail to see any very great advantage, because in the Solvay process the ammonia is mostly recovered so that the total amount required for renewals is not very great. Then, too, the two products are respectively an industrial and a fertilizer material, and the demands for the two are not adjusted to joint manufacture.

Occasionally there are rumors of a reintroduction of the Leblanc process. Some three years ago there were two or three such plants still in operation in England, and a very few similar works along the Rhine in Germany. There is none in this country, but the gossip usually arises from the fact that there are great deposits of sodium sulphate in Arizona, New Mexico and California. As thenardite, which is anhydrous Na_2SO_4, it is sometimes 98 per cent pure. When a cheerful promoter sees the deposits and reads the price of Glauber's salt as a drug or as a chemical need in the dye baths of the textile mills or in glass works he usually has visions of great wealth. These industries being all far away from the source of supply, to encourage production his next thought is the Leblanc process for soda! For this the materials

are brine, sulphuric acid, limestone and coke. While limestone is sometimes available it is the absence of coke and the problem of freights that usually kills the propositition. Such an undertaking, however, is a possibility.

In regard to potash, we have now a producing capacity of nearly 100,000 tons K_2O per year, or a little less than half of our requirements before the war. This can be extended, provided there is profit enough in the business, or provided technical research advances rapidly enough. It is likely to be two or three years before some establishments are shaken down to economic production. In addition to this, the problems of fuel, labor and freight are all in a state of flux.

The most promising prospects are certain California and Nebraska lakes; the greater deposits being in California. Here we have very strong natural brines in a hot, dry region. This is as rich as German or Alsatian products, dug out and brought up from many hundred feet underground. Now it is up to American technologists to get this salt by the aid of the sun and artificial evaporation as cheap as Germans can mine it, and it seems as though this were possible. It is also up to American producers to refine it at the same costs as Europeans can. The chemistry of the refining, including the separation of borax, and all other ingredients, is all worked out.

From 1000 to 5000 tons each are coming in from other sources, some of which may be materially increased. For lack of space we shall merely mention them: Dust from cement mills, beet sugar waste, molasses alcohol waste, Utah alunite, and Wyoming leucite. Two iron blast-furnaces are making potash recovery at present. This source may have considerable development in a couple of years. Working over the green sands of New Jersey may also become an important factor in the future, but they are not producing as yet. Kelp is practically dead for the present. The trouble was the cost of handling 90 per cent water which it contains when harvested, and the large amount of unprofitable organic matter to treat before the potash could be produced. The United States Government has an experimental plant in operation, with a view to developing enough useful byproducts from the kelp and thus to put the industry upon a commercial basis.

Gold and Silver Metallurgy in 1919

THE conditions that have prevailed in the gold industry during the past year have approximated stagnation. Probably not a mine operated throughout 1919 at full capacity, and all have faced increased costs. It is true that some reduction in the cost of many mining and milling staples has been experienced, but the benefit which might have been derived from these has been offset by the shortage of labor and its falling efficiency.

Naturally, the result has been retrenchment. Metallurgical developments have been such as have been dictated by the necessity of paring expenses to the bone; generally speaking, they have been refinements of existing practice rather than additions to known methods or to underlying principles. This condition, and the state of mind it inevitably produces, has also been in evidence in the technical press and the publications of the national societies. Passing these in review, we recall few of more than ordinary interest.

CROWE and LENNOX have described work done with Chilean mills at the Portland. It would appear that they have developed a mill that is superior to earlier designs, but it is not so clear that it has merit enough to threaten either the stamp- or the ball-mill. Ball-milling has contributed nothing new during the year, other than a steady improvement in technique and a more general understanding of the limitations of this type of machine. The stamp-mill operators have had an unsatisfactory experience with alloy steels, forced on them by war conditions as a substitute for hammered iron in such parts as camshafts. We understand that the steels have failed dismally, but feel that the failure may be redeemed when the manufacturers take time to give intelligent study to the exacting requirements of the stamp-mill. Several new screening devices, as the Mitchell and the Maxton, have been offered during the year.

ALLEN, in the *Engineering and Mining Journal*, discussing general tendencies in metallurgical practice, interested us in his insistence that this country has not wholly appreciated the advantage of gravity-leaching of finely crushed sand, suggesting by inference that our "all-sliming" work has been carried to an unwarranted extreme. We think there is much good sense in his argument. Sand-leaching is cheap; it is effective. Moreover, its possibilities have not been exhausted.

As an illustration, a single point may be instanced. For effective extraction, one of two conditions is essential. Usually, ample time must be allowed; sometimes it is sufficient that a certain minimum quantity of solution be applied. When the first condition prevails, the question of leachable depth of sand becomes of interest. Given clean classification, the depth may cover a considerable range without affecting leaching rates. Leaving out of consideration such factors as saving in cost of installation, increased washing time, etc., there remains the fact that, if 10 per cent more sand can be treated in a vat, extraction will be effected with 10 per cent less solution, and consequently with enrichment of effluent solution and reduction of all losses except the cyanide actually destroyed by the ore. Close attention of the problem is warranted.

The work of the copper men in leaching is of increasing interest to cyanide operators. The large scale of operations, the mechanical devices used, the manipulation of solutions, all carry valuable suggestions to practitioners in the older branch of hydrometallurgy.

CROWE'S process is a success, proclaimed as such not only by its continued introduction but also by criticism of the merits of its claim to letters patent. Of the soundness of the points raised against these claims we are not convinced, but that they should be made at all is excellent indorsement of the value of the process.

Of collateral interest is the publication by WHITE, in South Africa, of a method for the determination of oxygen in cyanide solutions. He apparently overlooked Sir WILLIAM RAMSAY'S work on the same subject, published eighteen years ago. Indeed, RAMSAY seems not only to have originated but to have pointed out the weaknesses of the method, which impresses one as being of rather limited application, too readily influenced by slight irregularities in the sampling and subsequent manipulation.

South Africa has been sharing our experience with unrest and disorganization of business; technical matters are for the moment of secondary importance. A new wage scale, with provision for a six-day week, has recently been negotiated on the Rand.

The great demand for silver has stimulated production everywhere, subject, of course, to the universal limitations imposed by unsatisfactory business conditions. BRYAN is again the prophet, and we have wondered at times, with the metal quotations before us, whether he may not have been, after all, an unduly modest conservative.

This reviving interest is being evinced by the reopening of old mines and camps, and interesting metallurgical problems may arise from these. Cyanidation will no doubt be the most favored method, as it has been almost the only one practiced in recent years and wider margins will extend its economic field. But in the bonanza days of the last century many ingenious processes were developed. In addition to the old Patio process, the Washoe, Von Patera, Augustine and Russell processes may be mentioned, to name but a few. Exhaustion of rich ores or falling prices of bullion led to the complete elimination of these methods. It is of interest to speculate whether the current market will bring back any of the old processes, rehabilitated with the machinery and equipment of the present day, and drawing on the experience of cyanide operators for supervision.

Then, too, the experiments in volatilization, quoted by LYON and RALSTON, and the work in this field by the staff of the Chief Consolidated, suggest that this radical innovation has possibilities. If the vagaries of the chloridizing furnace can be controlled, there may be a future for these methods.

Developments in Ceramics During 1919

ALMOST without exception ceramists have confined their efforts to adapting their technology to the available types of clays. They have never, except in a few individual cases, attempted to do much chemically with their raw material. Before the war great quantities of foreign clays were imported into this country. Little real effort was made to obtain them from among the vast and varied domestic deposits until the foreign supply was cut off. How successful were the clay geologist and ceramist has been frequently reported and is undoubtedly familiar to all.

However, the accomplishments of the clay chemist have been extolled with a weak voice indeed! It has almost become a dying one, for the work of our analytical friends in ceramics has furnished insufficient as well as only indirect guidance in this industry, where physical properties are mainly wanted and which can be controlled directly by physical tests.

Some valuable chemical developments in ceramics appear to have been accomplished during the past year in a laboratory located almost within hearing distance of the din from the narrow streets of the New York financial area. A practical process has been developed here for making a lean clay fat—a bond clay out of pure kaolin, which gives promise of a new era in refractories and the many industries depending upon them. The technical details cannot be described at present, but will be during the coming year.

In the fused silica industry progress can be noted at home as well as abroad. Since 1901 the variety of products has increased simultaneously with a decrease in prices. Large acid plant installations were made during the war and two domestic concerns are now operating on a small scale. The bulk of this material has been imported from England, but with the impending prohibitive duty once enacted, we will soon be fusing our own sand and use more fused silica equipment than can even be anticipated under present conditions.

Petroleum Industry In 1919

BUT a few years ago the low valuation of that undesirable by-product of the petroleum refinery, gasoline, gave impetus to the development of the internal combustion engine. The latter in turn was to create markets of inconceivable magnitude for the many petroleum products then practically unknown, ranging all the way from gas to pitch, surely a desirable substitute for the market of lighter products, ever becoming more circumscribed by the displacement of the candle and oil lamp with more modern methods of lighting.

In the past year the major products of the petroleum refineries—gasoline, lubricating oils, asphaltic residues, and coke—have largely been utilized so as to get more miles of transportation out of our several million motor cars and trucks. Just as it was the function of the lubricating oils to reduce the power lost by friction within the machine, so it was that of the asphaltic residue to produce less resistant roads and that of the coke to reduce alumina to aluminum for use in the fabrication of bodies and motor parts of less weight. All three of these factors helped to reduce the tractive energy required and therefore actually have a gasoline equivalent of considerable magnitude. An improvement in the technology of any one of these four products can be said to have a bearing second to none in regard to public convenience and pleasure.

Gasoline made by the cracking process is not stable and upon standing partly polymerizes into products which clog the carburetor, unless a considerable proportion of saturated hydrocarbon is mixed with the destructively distilled product. It has consequently been thought that the new cracking processes were of limited application. Some investigators have anticipated this difficulty by working out hydrogenation processes for building up the saturated hydrocarbon content. However, it has been found that by making prompt delivery of the destructively distilled gasolines, they will usually be consumed before sufficient time is given for the polymerization to take place.

None of the cracking processes gives the most desirable conditions for getting maximum yields. Temperature, heat input and pressure are not so difficult to control, but they must now be maintained below the ideal, due to the safety limitations of the equipment used. Considerable work along these lines is being done which gives promise of development of great importance. The oil fraction to be cracked is passed through a bath of molten lead. Evidently, the pressure is easily controlled by the head of metal maintained above the oil inlet. Very great pressures can thus be obtained without danger of ruptured containers and conflagrations. The temperature is controlled by regulating the heat applied to the container of the metal in conjunction with which the rate of the oil feed and its dispersion governs the flow of heat into the oil.

Asphaltic residues are usually brought to the required specifications of melting point, penetration, or tempera-

ture susceptibility by proper mixing of bases and blowing with air. It has been found that a better product is made by using a very high rate of air input and shorter heating periods than has generally been adopted hitherto.

In one of the large Eastern refineries, a segmental still-head has been designed so that the coke zone can be readily exposed and the deposit removed mechanically. Stills thus equipped will not have to stand idle for days to be cooled down to a temperature at which men can enter to clean them. Many asphalt and other stills containing bituminous solids will eventually be equipped with some such type of segmental plate and mechanical cleaner in preference to carrying excess equipment for peak operation.

During the year the petroleum refining companies formed a Petroleum Institute which will undoubtedly have considerable influence in many aspects, legislative, technical or economic. At the present time new specifications governing the use of fuel oil are being discussed. The Institute keeps its members informed as well as obtains and makes known their opinions on points at issue. It is planned to organize a technical section which will afford men the long and much needed opportunity to meet, swap ideas and return to their plants with their minds opened and stimulated.

Review of the Year's Advance in Rubber

THE shifting from a war to a peace basis has been accomplished by the rubber industry with no great difficulty. This was due chiefly to the fact that rubber has a wider range of application in the arts of peace than in war. In 1917 and 1918 the rubber factories were running at minimum production and every effort was put forth to aid our Government. Peace brought a decrease of production in some lines, but the effect was just the opposite in rubber. The stocks of all the major companies began to rise. Production organizations were expanded, and since then practically all companies have been hard pressed to fill their orders. This is particularly true in the tire business, which had been considerably under the ban due to the restriction of crude rubber imports.

One of the most gratifying results of the war has been the better appreciation of the value of the chemist and chemical engineer. This lesson has apparently been well learned by the rubber industry. During the past year practically every company has either installed or enlarged its laboratory, and the tendency is to give more weight to the opinions of its chemists. The day of the rule-of-thumb compounder is nearly over. His place is being taken by the rubber chemist, whose duty it is so to combine science and common sense that products may be improved and cheapened, while at the same time production may be increased and a uniform quality maintained.

Another achievement of the year has been the reduction in the number of tire sizes for pleasure cars. Through co-operation between the Society of Automotive Engineers and the tire makers many unnecessary sizes have been eliminated. The resultant saving in cores and molds has been enormous.

There is a marked tendency for a wider application of the cord principle in tire construction. There are now no 5-in. tires which are not cords. It is predicted that before long all sizes, even down to 3 in., will be made in this way. While cord tires have a higher initial cost than fabric, they do give a lower cost per mile and more comfortable riding, which is due to the greater pliability of cord casings over those of fabric. This increased pliability has permitted the development of pneumatic truck tires, which are now past the experimental stage and are being manufactured in quantity by several large companies. There is a growing tendency to equip all long-haul trucks with pneumatics and to use solid tires only on very good roads and for short hauls. This is due to the fact that trucks so equipped can average 30 to 35 miles per hour over a long trip.

Because of the failure of electrically driven street cars adequately to care for the traffic in many large cities, more and more attention is being paid to the operation of buses which are simply large trucks with special bodies in which seats are provided for from 25 to 75 persons. Such buses, equipped with pneumatic tires, are comfortable and make very good time. Since no tracks or trolley wires are required, they are free to operate on any street. There is a great saving in initial expense and upkeep, and since only one man is required to operate most of them, there is a saving in labor as well. Keen students of the traction problem say that the street car is doomed.

The growing of long staple cotton equal to the best Egyptian or sea island varieties in Arizona is of particular interest to American tire manufacturers. The success of the project is now assured and many thousand more acres of former desert land will soon become productive.

In tubes the consensus of opinion seems to favor increased pole size. It has been found that if the diameter of the tube more nearly equals that of the casing its life is longer. In other words, the lower the strain the tube is under when the car is still the better it will age.

American tube makers are showing great interest in antimony sulphuret. It is admitted by most rubber chemists that a properly compounded antimony tube made with rightly prepared sulphuret is absolutely the best tube that has been made to date. The American branch of a French rubber company enjoys a national reputation because of the high quality and long life of its tubes. There are now approximately six firms in this country making antimony sulphuret, and antimony tubes are being manufactured by quite a number of rubber companies.

The pioneer work of EATON, GRANTHAM, DE VRIES and others in producing fast-curing rubber of high quality is now bearing fruit. At least two of the large rubber companies are producing it on their own plantations and using it in their compounds. There is an increasing tendency among rubber growers to pay more attention to selective breeding and like problems with a view to making the *Hevea* tree more productive.

In the accelerator field hexamethylene tetramine is now almost as extensively used as thiocarbanilide was a few years ago. Another accelerator that has recently come into general knowledge is the reaction product of dimethylamine and carbon disulphide, dimethylamine-dimethyl-dithiocarbamate, which is the most powerful curing agent known to date. A quarter of 1 per cent of this substance will give a good cure in three minutes heating to 140 deg. C. If this same stock is made into a cement and the accelerator added in benzol solution, the whole mass will

set to a very stiff vibrant jelly in about a week's time at room temperature. There are as yet no practical applications of this accelerator, but one may reasonably expect the development of a line of self-curing cements and patches at no very distant date.

There has been very little labor trouble in this industry, chiefly because rubber workers are well paid and the large majority of them are home-owning Americans. Several firms require their foreign-born workmen to become American citizens or quit. In many factories there is a healthy spirit of co-operation between the men and the management which has brought about a good appreciation of each other's responsibilities. There is no room for Bolshevism here.

The coming year should be a very fruitful one for the rubber industry. The demand for rubber goods of all kinds was never greater, not only at home but abroad. Materials are available in quantity and labor is willing. These are certainly the principal factors necessary for prosperity.

Hydrometallurgy and Pyrometallurgy Of Copper in 1919

NEW smelter construction appears to be centered in South America, and the Andes Mountains bid fair to witness a building boom such as occurred ten years ago in Arizona. Strangely enough, each one of the four leading copper producers is engaged in the design, if not in actual construction, of new and larger plants. Braden has completed plans for a new blast-furnace plant some five miles below its present mill site, concentrates to be transported by rail or aërial tram. Cerro de Pasco has started on the construction of a new smelter at Oroya, some distance below La Fundicion, the site of its present one, planned and built some 15 years ago. Its new plant (which will probably not operate before 1922) will have two blast and two reverberatory furnaces, and will make about 100 million pounds of copper annually—somewhat more than the present installation gets with nine smaller smelting units. Chuquicamata is engaged on a project which calls for doubling its present output—the same leaching system will be utilized, and the extension will be on the same site. Andes Copper has its preliminary work on its property at Potrerillos well in hand, the metallurgical details having been carefully worked out by LAIST at Anaconda and the mechanical design for a 12,500-ton unit nearly complete in all respects. Briefly the scheme for the oxidized capping will consist of crushing to ½ in., leaching by downward percolation in rectangular concrete tanks containing one day's ore receipts, precipitation by pig iron or SO_2 and refining by melting down under bone ash.

Of this new construction it is seen that over half is devoted to leaching—to hydrometallurgy—and the conclusion is safe that from now on the sulphuric acid leach will be given careful consideration by those contemplating treatment of low-grade oxidized ores. As a process for roasted sulphides it is not so attractive. For instance, ROGERS at Anaconda has found that table tailings from old dumps containing 0.7 per cent copper can be reground and reduced to a 0.2 per cent tail by flotation as cheaply as the same material can be roasted and dissolved in its leaching plant, and the former method is now practiced using either one section exclusively or distributing the available sands throughout the mill.

But there is a range between straight sulphide ores and straight oxide ores where the losses in either process may be too much to countenance—in fact much work is being done, particularly in Arizona, on combined methods which will catch the oxidized copper comprising the bulk of the tailings values. If the ore contains few acid-consuming materials—a point impossible to determine from the usual chemical analysis—it would obviously be good engineering to leach coarse material, then grind and float the cleaned sulphides, a scheme which ALDRICH is now operating at Inspiration in a 30-ton experimental mill. On the other hand, the Miami Copper Company, in co-operation with VAN BARNEVELT of the Bureau of Mines, is investigating a scheme for handling mixed ores which entails fine grinding followed by flotation. The pulp is then passed through a large wooden drum against a current of SO_2, which leaches soluble copper out as sulphite, changing rapidly into sulphate, however. The whole mass then goes through a very long ball mill, acting not as a grinder but as a precipitator, after which the cement copper is to be recovered by flotation.

Precipitation of copper sulphate presents the most interesting problem in leaching. Some ores may be so fortunately constituted that any contained iron is insoluble; then the solutions may be electrolyzed almost completely without precautions to lower the ferric content and with the simultaneous production of little or no cement copper. On the other hand, manipulation may change the ratio of cement to electrolytic copper. Thus, at New Cornelia, during curtailed production TOBLEMAN found that the longer the time of leach and the lower the corresponding acid concentration, the less would be the amount of impurities dissolved and consequently the greater the proportion of electrolytic copper to cement copper produced, a very desirable condition. On some ores, solutions may become so foul that only a small percentage of copper is removed in one passage through the tanks and that at a low ampere efficiency; this condition, coupled with a high cost of electricity and acid, would make some clean method of chemical precipitation quite attractive. FRICK at Anaconda has therefore worked out the details of precipitation by SO_2 for the new Andes plant. In this scheme, leaching solutions, thoroughly reduced by liquid SO_2, pass through heat interchangers into lead-lined autoclaves, there to be heated to 150 deg. C. under 125-lb. pressure for 4 hours, when half of the metal is thrown out as bright red copper crystals with the generation of sulphuric acid according to the formula

$$CuSo_4 + SO_2 + 2H_2O \rightarrow Cu + 2H_2SO_4$$

The hot mixture is then discharged through interchangers and thickened; the liquid returned to circuit and the copper dried and furnace refined.

Reverberatory and blast furnace still maintain supremacy in their individual bailiwicks, despite rumors of the latter's demise. Anaconda has cut one of the 51-ft. units into the two 15-ft. stacks from which it sprang, and runs the small one only intermittently, while KUZELL has just doubled the capacity at Clarkedale by a battery of new reverberatories, and other Southern plants have hung up wonderful records for long campaigns. Thus, CLARK at Calumet & Arizona, by widening furnace, raising verb and enlarging uptake, has been able to smelt regularly 700 tons of dry charge daily plus 100 tons of converter slag, with an oil consumption of 0.7 barrel of oil per ton. Large modern

reverberatories are doubtless pre-eminent for smelting fusible fine charges, especially where fuel and silica brick are cheap. On the other hand, a blast furnace has all the best of the argument with refractory, coarse ores, high in sulphur, especially in places where power is relatively cheap and cost of coke not prohibitive. Even fines may be smelted to advantage after sintering or nodulizing, as will be done in Braden's new plant, and introduction of powdered coal through tuyeres bids fair to remove the disability caused by expensive coke.

The soundness of the latter idea seems definitely established. Early in 1918, CAVERS ran a blast furnace at Tennessee Copper for a fortnight, blowing pulverized coal through ten tuyeres on one side of the furnace. But very little coke was charged occasionally, it being replaced by two-thirds its weight in fine coal. This practice was discontinued because of unburned carbon discoloring the acid; but later experiments at International Nickel have shown beyond question that pulverized fuel can replace a considerable percentage of coke, a result confirmed at Cerro de Pasco, by RICHARDS at Garfield and by HAMILTON at Midvale.

VAN ARSDALE and MAIER have published a most important contribution as to the exact condition of copper in furnace slags. To a certain small extent copper sulphide is held as a true solution, but the balance occurs as globules of white metal, floated by attached bubbles of SO_2, the latter gas formed by reduction of iron sulphide by ferric iron in the slag. Continued settling would not recover either the dissolved or the buoyed metal, and this can only be done by changing the composition of the slag so as to practically eliminate the occurrence of ferric oxide. In the light of this information, data on the operation of the large slag furnace at Anaconda are interesting. Here liquid converter slag is poured through a side door of a reverberatory, banked by high-sulphur calcine and siliceous tailings. Reaction with this material melting along the sides of the bath reduces the magnetite in the converter slag and tailings are dissolved so that whereas the incoming slag carries 4 per cent copper, 63 per cent iron reported as FeO, and 23 per cent silica, the outgoing slag has been reduced to 0.6 per cent copper, 53 per cent FeO and 34 per cent silica.

Anaconda's new Cottrell plant started during the summer, giving good clearance of very fine fume. The relative difficulty and expense of catching fume and dust are vividly exhibited by a comparison of this monumental plant with a little plate treater tucked away in a short section of gas flue at Tooele. In comparison it is only a toy, yet it gets 90 per cent of the dust passing a dust chamber, even when handling gas from twelve McDougalls at 20 ft. per sec. With the problem of how to catch solids now solved, the next to appear in the near future will be how to get rid of the unusual substances which will accumulate and finally saturate the smelter system. How to do it at a profit will at times be subordinated to the compulsion to do it in some way which will create no nuisance or positive danger.

Refineries were left with much war-time excess capacity as well as war-time copper on hand, and it is hardly probable that any considerable plant extension will occur for some years. An interesting possibility for the future is the casting of large ingots to be rolled direct without cooling into rods or sheets in mills built closely adjacent to the furnace refinery, a practice long standard for blooming mills in steel plants. ANTISELL, at Raritan, has been able to use a high-sulphur Mexican topped oil of high specific gravity in cathode-melting furnaces, without any harmful effects from high sulphur in the resulting wire bars. If electroyltic copper, notoriously sensitive to minute impurities, can thus be melted without slag protection and with impunity with what is commonly regarded as dangerously impure fuel, the harmful effects of SO_2 in furnace gases in other metallurgical operations are possibly overdrawn. It may be remembered that high ash pulverized coal was not suitable for reverberatory smelting on account of an "insulating blanket of fine ash settling upon the slag," until some ignorant person went and used it!

Even in rock-ribbed Michigan are signs of change visible. Needs must, for the Federal Trade Commission's reports show that as a group, Lake copper costs more than that from deep mines or porphyries in the West, even the biggest Michigan companies returning costs of from 16.2 to 16.6 cents per pound, while at the same time the price differential between Lake and electrolytic copper has definitely vanished. Deep mining, low-grade ores and fine concentrates point to a certain revision of Lake practice to that more modern; at least some simple labor-saving devices are necessary purely on account of the continual decrease in number of laborers of the broad-back, narrow-forehead type. The cheapest copper coming from Michigan is probably that reclaimed from regrinding tailings, and it is even possible that the old slag dumps can be made to yield metal more economically than can an ore body 5,000 feet below.

The Steel Industry's Growth

THE actual commercial capacity of the United States for producing steel ingots crossed the 50,000,000-ton mark in 1919. To secure a basis for computation one must go back to the year 1916, for in none of the three years intervening has there been opportunity to test the industry under fair working conditions. In 1917 and 1918 there were transportation difficulties curtailing the output at one time or another, and in 1919 there was a lack of orders for a large part of the year. The steel ingot production in 1916 was 41,401,917 gross tons. Deducting the estimated production of new capacity installed during 1916, and adding about 80 per cent, to be conservative, of the rated capacities of new installations from January 1, 1916, to January 1, 1920, one reaches a figure slightly in excess of 50,000,000 tons. It seems perfectly safe to assert that given the same operating conditions as obtained in 1916 such a tonnage can be produced.

On the whole, there has always been sufficient rolling capacity to take care of ingot production. The sum total of rolling capacity is always well in excess, as provision must be made for variations in the distribution of demand. Except for the dislocation produced by the rolling of shell steel, with heavy discards, the production of finished rolled steel, in rods, skelp, sheets, plates and shapes, has always run approximately 76 per cent of the ingot output. Hence the capacity in finished rolled steel may be taken at fully 37,500,000 gross tons a year, or 725,000 tons a week. The year 1920 opens with a conspicuous shortage of steel, and with production at 550,000 or 600,000 tons a week, and thus it may be seen readily that making up the shortage is chiefly a case of

bringing production as nearly up to the capacity rate as may be.

Electric steel has made a magnificent record in the past four years. Previously the statistics had given it a little bit of a black eye. It looked bad that production of electric steel ingots and castings should jump from 13,762 tons in 1909 to 52,141 tons in 1910, and then show a lower production in each of the four years following. The excess production in 1910 was chiefly of rails, made for experimental purposes. For many, if not all, other uses the production of electric steel increased in the four years following 1910, with the exception, of course, of 1914, which was an "off" year in practically all respects. The remarkable growth of the electric steel industry is shown by the following production statistics, the figures referring to gross tons:

	Ingots	Castings	Total
1909	13,456	306	13,762
1910	50,821	1,320	52,141
1911	27,227	1,878	29,105
1912	14,147	4,162	18,309
1913	20,973	9,207	30,180
1914	15,458	8,551	24,009
1915	46,348	23,064	69,412
1916	126,048	42,870	168,918
1917	239,632	64,911	304,543
1918	403,068	108,296	511,364

While the war was largely responsible for the rapid increase in the production of electric steel, there has been no retrogression since hostilities ended. Instead there has been much new construction, at a rate not far below that which obtained during the war. The half-million ton output of 1918 is large in itself, but the tonnage is made the more impressive as the output of a young industry when it is observed that the steel industry of the U. S. was regarded as very large at the time the United States Steel Corporation was formed, early in 1901, and that the 1918 output of electric steel is 5 per cent of the output of the entire steel industry just before the formation of the Steel Corporation.

The pig iron producing capacity of the United States, on a fair estimate of actual production under normal operating conditions, not a summation of rated capacities of stacks, is about 45,000,000 tons a year, with a dozen furnaces being built, to add about 2,000,000 tons to production. Output for years past has grown not merely by the erection of new stacks but by the remodeling of old stacks and by apparently slight changes in equipment and methods whereby individual furnaces have materially increased their output.

Statistics have now accumulated for a number of years of the consumption of iron ore, fuel and limestone by blast-furnaces, so that some comparisons may be made. Beginning with 1909 there are complete statistics of the quantities of iron ore, mill cinder, scale, etc., and limestone consumed by the furnaces, while the fuel consumption figures are complete since 1912.

The average iron content of the Lake Superior ores has been going down more or less steadily for about 20 years, partly by reason of the exhaustion of the choicest deposits and partly because expanding requirements necessitated the opening of lower-grade deposits. One might suppose, therefore, that the average ore consumption of the whole industry, per ton of iron made, would increase. The ore consumption was 1.886 tons per ton of pig iron in 1909 and 1.895 tons in 1910, since which year it has been less, and 1918, with 1.853 tons, was almost the lowest year of the ten for which statistics are available. The statistics, however, furnish a plain offset to this, in that while the consumption of mill cinder, scale, etc., was 0.098 ton in 1909 and 0.102 ton in 1910, it was 0.130 ton in 1918. The total of the two was almost constant in the ten years, the maximum being 2.018 tons, in 1911, the minimum being 1.937 tons, in 1917.

Scale is much richer in metallic iron than any of the iron ores available, and scrap is nearly all metallic iron. Taking the industry as a whole, there was practically no choice as to the consumption of scale. Presumably the blast-furnaces consumed nearly all the scale that was produced in rolling steel. As the production of the steel has increased more rapidly than the production of pig iron, a smaller percentage of the total pig iron output being used in foundries, the relative supply of scale has increased at least slightly. The proportions of the charge in 1909 were 95 per cent iron ore and 5 per cent cinder, scale, scrap, etc., while in 1918 the proportions were 93.4 per cent and 6.6 per cent. The increase in the material other than ore may be attributed entirely to an increase in the scale available, which would mean that the blast-furnaces are not using larger quantities of scrap.

Seeing the uniformity of the figures, one might possibly incline to the notion that blast-furnace managers have endeavored to regulate this matter for themselves, using scrap as necessary to get out certain tonnages. It is interesting that in ten years the amount of ferrous material has deviated only slightly from a mean of about two tons per ton of pig iron.

It should be noted that in statistics like these, where simply the totals for the whole country are considered, the declining iron content of Lake Superior ores is balanced, to some extent at least, by two other influences. One is that rich ores have lately been imported to a greater extent than formerly, while another is that the proportion of Lake Superior ore to total ore has increased, and the Lake Superior ore remains of higher iron content than the Southern ores. The total production of iron ore in the United States increased from 51,155,437 tons in 1909 to 69,658,278 tons in 1918, but the production of all ore outside the Lake Superior region was practically stationary, being 9,291,802 tons in 1909 and 9,878,484 tons in 1918.

The fuel statistics are complete only for 1912 and subsequent years. They show, as to the coke furnaces, 2436.5 pounds per ton of iron for 1912 and 2375.2 pounds for 1918. Very small quantities of bituminous coal were used, and weighed in with the coke, the quantities being so small as not to affect sensibly the showing of fuel consumption. Comparing 1912 and 1918, there was a slight decrease in the quantity of ferrous material used, and these two changes are almost precisely in proportion. There is a larger decrease in the consumption of limestone than in the consumption of coke, but very precise comparisons cannot be made because the limestone statistics are not separately given for coke furnaces, the anthracite totals being included.

The general conclusion one may draw from the statistics is that no great change has been occurring in these matters, taking the industry as a whole. At individual plants furnace managers may effect important changes, but the industry as a whole is operating much the same now as ten years ago.

Actual production in 1919, which was distinctly an "off" year, was approximately 30,500,000 tons in pig iron, 33,000,000 tons in steel ingots and 25,000,000 in finished rolled steel, or in the neighborhood of two-thirds of capacity.

Manufacture of Pure Tungsten Metal—Operations at the Fansteel Products Company

Smelting and Leaching the Ore—Production of Ammonium Paratungstate, Tungstic Acid, and Oxides—Reduction Operations and Design of Furnaces Used to Secure Pure Metal—Working Qualities of Product—Future Markets

BY CHESTER H. JONES

FROM comparative obscurity and classification with the rare elements twenty years ago, tungsten has come to take a place among everyday substances in the metallurgical world. It has largely received prominence through use in the steel industry and later in the incandescent electric lamp manufacture. Automobile ignition equipments have also consumed large quantities of tungsten metal for contact points.

We have been accustomed until recent months to think of these substances in the metallic state as powders of varying impurity. The steel industry has called for only a crude refining of the ore; the lamp manufacturers have kept the processes secret and made little attempt to market the fine wire they produce; and makers of tungsten contact points have made no effort to market the pure metals for general application.

It is hoped that by a description of the process of producing pure metal from the crude ore and an outline of the properties of the final and intermediate products the chemical industries may find particular application to supply needs hitherto unfilled.

TREATING THE REFINED ORE

The wolframite ore is received in 100-lb. bags at the plant of the Fansteel Products Co., North Chicago, the present supply coming from Korea. It is a hand-picked product about pea size (Fe,Mn) WO_4, heavy dark gray to black, sub-metallic crystals, orthorhombic in appearance, but actually monoclinic. The material has a hardness of 5 to 5.5; specific gravity 7.1 to 7.55; streak, dark brown to black; opaque, brittle and slightly magnetic. The chemical analysis is about as follows: WO_3, 73 per cent; tin, 1 per cent; copper, 0.05 per cent; manganese oxides, silicon oxides and iron oxides, 25.95 per cent.

This ore is first crushed in a small jaw crusher and subsequently ground to a coarse brown powder in a Braun planetary disk crusher. It is then mixed with commercial soda ash in a ratio of one part of WO_3 content to one part of Na_2CO_3, plus a 15 per cent excess of soda ash. This mixture is placed in a belt-driven Abbé pebble mill, about 1-in. diameter pebbles, and reduced to pass 100-mesh screen.

FIG. 1. REVERBERATORY FURNACE—OUTLET SIDE

ROASTING

The fine mixture is shoveled by hand into a small reverberatory furnace in charges consisting of about 200 lb. of ore to 100 lb. of soda ash. It is hand-rabbled

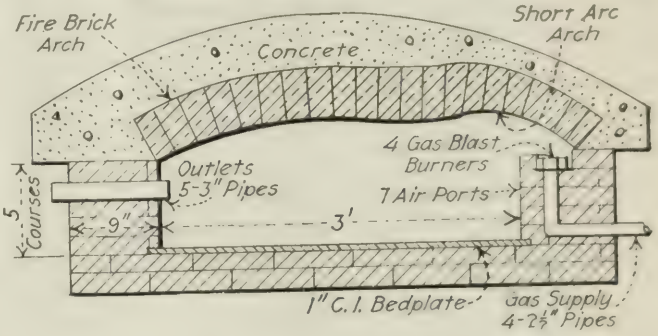

FIG. 2. TRANSVERSE SECTION OF REVERBERATORY FURNACE

at a temperature of about 800 deg. C., just sufficient to convert all the manganese oxide to dioxide during the following main reaction:

$$2FeWO_4 + O + 2Na_2CO_3 = 2Na_2WO_4 + Fe_2O_3 + 2CO_2$$

The operation requires about 2 hr. per charge. Care must be taken that the temperature does not mount high enough to fuse the mass, which must be kept in a pasty condition. When the reaction is complete the hot material is raked out in cast iron pans to cool.

DESIGN OF THE FURNACE

The furnace is located out of doors and its general appearance may be noted in Fig. 1. This view shows the five fume outlet holes and the single door, used for charging, discharging and as a rabbling port; with flat pan before the opening ready to receive the finished roast.

The structure is erected on concrete base with concrete roof to protect the brick work from the weather. Length of inside is 5 ft., with 3 ft. width of hearth and five brick courses from floor to point where arch intersects. Fig. 2 shows sectional sketch of furnace. Ordinary fire brick is employed as a refractory, but is unsatisfactory because of rapid deterioration, especially on the floor and side walls where the charge comes in contact with the brick. For this reason a 1-in. cast iron bed plate is inserted over the floor. This resists

FIG. 3. REVERBERATORY FURNACE. GAS FEED SIDE ON RIGHT

the chemical action of the charge, but is not suitable, as its continual warping and crawling under the temperature changes break up the walls, as can be seen in Fig. 3. In the construction of a new furnace magnesite or dolomite brick should be used.

The gas supply system appears on the right in Fig. 3. Gas is furnished at about 3-lb. pressure and the air blast is maintained by a small positive-pressure blower. The Zander blast burners furnished by the Chicago Pulley & Shafting Co. are imbedded in the brickwork to protect from heat in the main chamber, and the flame near this point is directed downward by the small arch constructed in the main roof.

Leaching the Roasted Ore

The cooled matter from the furnace is crushed to pea size in a jaw crusher and taken to the leaching room. Here it is shoveled into wooden tanks 4 ft. in diameter and 4 ft. high, where solution with process water is agitated by wooden mechanical stirrer. The sodium tungstate goes into solution quite rapidly, but the liquor is usually agitated over night to assure complete dissolving. A 2-in. pipe line near the bottom of the tank connects up with a small centrifugal pump, which forces the slurry into a 36-in. Sweetland filter press made by the United Filter Corporation.

The clear filtrate, Na_2WO_4, is discharged through a 2-in. hose to the precipitating tanks. The sludge, consisting of MnO_2, Fe_2O_3 and other oxides, is washed in the press and washings returned to mixing tank. When thoroughly cleansed of all tungstate the residue is thrown away. In testing the first solution in the mixing tanks a hydrometer is employed. If a 50 deg. Baumé reading is secured the solution is saturated. It is not allowed to go below 30 deg. Baumé.

Commercial Tungstic Acid

The precipitating tanks are wooden or stoneware tubs about 3 ft. in diameter by 3 ft. high. The clear liquor is heated by live steam jet from hose bubbled directly into the solution. When brought to a boiling temperature the hose is removed and a 20 deg. Baumé solution of $CaCl_2$ is added in excess. A white flour-like precipitate of $CaWO_4$ is thrown down. This is washed with process water, by decantation, until all the excess chlorides are removed.

$$Na_2WO_4 + CaCl_2 = CaWO_4 + 2NaCl.$$

The calcium tungstate is baled over to glazed-ware bowls about 3 ft. in diameter and 2.5 ft. deep and a 20-gal. carboy (120 lb.) of commercial hydrochloric acid is added to excess. A stoneware pipe is inserted in the solution to supply the live steam for boiling. The reaction

$$CaWO_4 + 2HCl = CaCl_2 + H_2WO_4$$

is continued over a period of about 1 hr. The yellow precipitate of tungstic acid is allowed to settle and the excess $CaCl_2$ and HCl are siphoned off. This acid and chloride solution is treated with lime to obtain $CaCl_2$ for the preceding operation.

The yellow precipitate is shoveled to a General Ceramic Co. suction filter, operating under about a 20-in. vacuum, and is repeatedly washed with process water. The resulting product has the following average analysis:

H_2WO_4	99.53 per cent
FeO	.02 per cent
Al_2O_3	.05 per cent
CaO	.20 per cent
SiO_2	.20 per cent

This is the ordinary commercial tungstic acid known on the market as Grade A. It is seen to be impure as compared with the required acid.

Purification of Tungstic Acid

The washed precipitate is removed from the suction filters to the ammonium paratungstate room by hand and dumped into a high enamel-lined steel tank 3 ft. in diameter by 5 ft. This tank is painted on the outside with aluminum paint to resist ammonia fumes. Sufficient distilled water, together with about 5 gal. of concentrated ammonium hydroxide, is added to nearly fill the tank and obtain a 7 per cent solution of ammonium paratungstate.

A 1-in. jet of live steam is added through the hose to bring the solution to boiling. Fig. 4 shows this tank with the steam hose hanging down between the windows.

The hose on the right-hand edge of the tank is connected to a centrifugal pump which decants the liquor to a 12-in. wood-leaf Sperry filter press shown in the foreground. This press is equipped with filter paper between the leaves and the spigots are replaced by glass tubes inserted in rubber corks, as shown emptying into the wooden trough in Fig. 5. The clear filtrate of paratungstate is carried by 2-in. hose shown at the lower right hand of Fig. 4 to 150-gal. enameled, steam-jacketed Elyria kettles. The second ammonia room mentioned later is equipped with Pfaudler kettles.

Reference to the kettle in Fig. 5 will show the steam piping, the liquor hose across the floor from tank to pump and the wooden hood over the evaporating kettles,

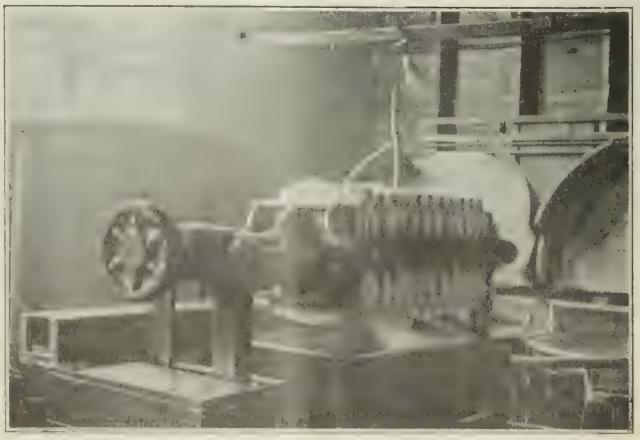

FIG. 4. AMMONIA ROOM, WHERE AMMONIUM PARATUNGSTATE IS MADE

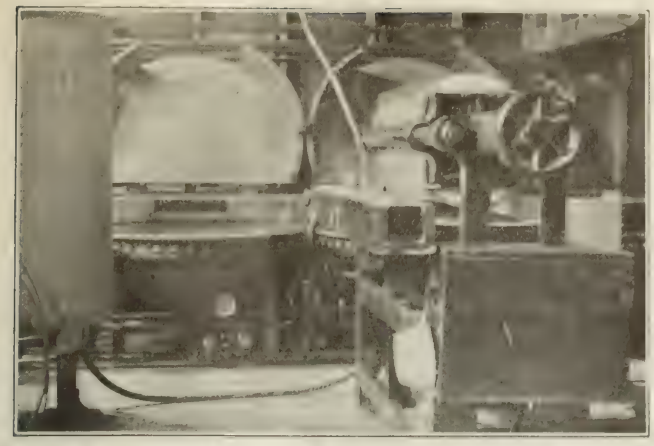

FIG. 5. AMMONIA ROOM SHOWING TANK, KETTLES AND FILTER PRESS

lifted out of place. This hood collects the ammonia fumes during evaporation, which are carried off by an exhaust fan. The rectangular exhaust opening is shown in the wood housing directly back of kettle.

The filtrate is evaporated to a small volume in the pans and dried to a mud in stoneware suction filters and is washed with distilled water. The sludge from the filter press consists of impurities and some quantity of blue mud, ammonium metatungstate. This, together with the filter paper, is saved for the scrap salvage mentioned further in this article.

The white mud, ammonium paratungstate, is removed to the nitric acid room, where 40-lb. batches are placed in the 7-gal. steam-jacketed enamel-lined bowls shown in Fig. 6.

C.P. nitric acid, about 40 per cent solution, is added. The white precipitate is slowly changed to the yellow tungstic acid H_2WO_4 as the liquor is heated. The color of this product is a much brighter yellow than the original commercial tungstic acid noted at the beginning of the purification process.

The nitric acid fumes collected in the hood shown over the kettles in Fig. 6 are exhausted from the room by a 6-in. General Ceramic Co. stoneware fan direct-connected to a 2-hp. General Electric motor running at 1800 r.p.m. Considerable trouble with the handling of these fumes was experienced until the installation of this apparatus, which has been giving perfect 24-hr. service for a year.

The contents of the kettles are removed on completion of the reaction to two 10-gal. stoneware suction filters, where they are washed repeatedly with distilled water. In spite of the processes through which the tungsten compound has passed it is not yet of sufficient purity for production of the metal, and is therefore taken from these filters and returned to the ammonia room, redissolved as paratungstate, filtered in a Sperry press, evaporated, filtered and washed with distilled water in suction filters and returned to the nitric acid room.

It is again treated with C.P. nitric acid solution, filtered and washed repeatedly in suction filters and dried to give the pure tungstic acid needed for metal production.

Pure Tungstic Oxide

The next operation consists in placing the yellow tungstic acid in No. 6 fused silica crucibles, 44 crucibles per heat, and placing in a gas-fired oven. The temperature is raised to about 1000 deg. C. and the following reaction occurs:

$$H_2WO_4 + \text{heat} = WO_3 + H_2O$$

The resulting tungstic oxide is a light green color due to mixture of WO_3, yellow, and lower oxides of tungsten, which are blue. The following analyses give some idea of the purity of this product:

SAMPLE NO. 1

WO_3	99.94 per cent
Fe_2O_3	.024 per cent
Al_2O_3	.018 per cent
CaO	.009 per cent
P	Trace
SiO_2	.010 per cent
S	none

SAMPLE NO. 2

WO_3	99.96 per cent
Fe_2O_3	.0075 per cent
Al_2O_3	.016 per cent
CaO	.028 per cent
P	none
SiO_2	none
S	none

A very pure tungstic oxide has been produced in small quantities for special purposes with the following analysis:

WO_3	99.995 per cent
CaO	.005 per cent

The metal tungsten is of higher purity than the foregoing analyses because of volatilization of the impurities. All oxides produced are analyzed and if a content above 0.02 per cent Fe_2O_3 is present they are returned to the process for further purification.

Raw Materials Used

The process water enters two Hygeia Filter Co.'s Steward non-agitator filters connected in parallel and is distilled in a 55-gal. Barstead automatic still. A 750-gal. storage tank supplies the requirements for the pure water.

About 40 per cent of the output at the present time consumes scrap tungsten for the raw material. All scrap metal, filter paper, sludge from ammonia rooms, sweepings, etc., is reconverted by ignition in a small gas-fired brass-melting furnace with sodium nitrate to get the soluble sodium tungstate. Thirty lb. of sodium nitrate and 25 lb. of scrap constitute the usual charge. The powdered metal and sludge may be thrown in with a reverberatory charge. The process on scrap then continues as described for the ore.

Difficulties in Chemical Process

The over-all efficiency of the chemical process is 90 per cent, that is, 90 per cent of the tungsten in the ore

FIG. 6. NITRIC ACID ROOM—STEAM-JACKETED EVAPORATING BOWLS

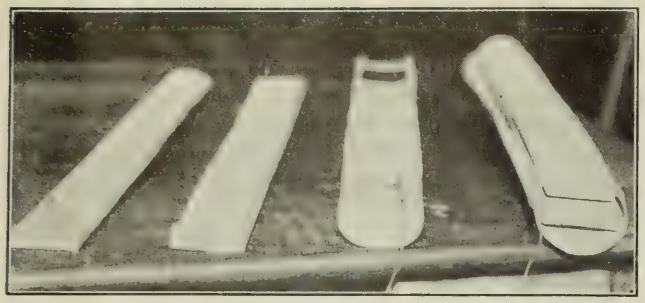

FIG. 7. NICKEL BOATS AND TRAYS FOR FURNACE

is recovered. The greatest difficulty in the work is to maintain absolute cleanliness in each step of the operations. The item that has given the most trouble in this connection is the refractory containers, especially the enamel linings in tanks and evaporating kettles. No enamel lining has been found that will remain perfectly intact under the action of hot acids and alkalis. Alkaline conditions cause chipping of linings, resulting in the presence of iron, silica and silicates in the process. The linings become de-vitrified. These impurities occur in actual combination with the product and not as mechanical inclusions.

When the impurity is carried through to the metal product the physical structure of the sintered bar is weakened to a marked extent. Continual supervision is necessary to prevent this condition.

Reduction of WO_3 to Tungsten Powder

Until recent years the only commercial methods of reduction were (1) by hydrogen and (2) by use of carbon. The latter was generally employed because of difficulty in control and of completion of reaction with hydrogen. As a result it was impossible to secure pure tungsten. The hydrogen method has been improved upon so that it is now entirely used in the Fansteel Products Co. plant to secure the purest metal obtainable. Ten thousand cu.ft. of hydrogen are consumed daily in the process.

The WO_3 powder is placed in small nickel trays about 18 in. long, which are stacked in pairs in nickel boats as shown in Fig. 7. The two trays appear on the left; the third object is the nickel boat empty, showing cross-wire supports and wire for pulling out of furnace, and on the extreme right is the boat containing two loaded trays. This charge is placed in a closed-tube type electric furnace, heated to about 1200 deg. at completion of exothermic reaction, through which passes a stream of pure hydrogen. The reaction is as follows:

$$WO_3 + 3H_2 = W + 3H_2O$$

The tungsten is withdrawn as a gray powder. The excess hydrogen passing out is dried from water content and re-enters the system.

Design of Reduction Furnace (Old Type)

The older type of furnace, still in continuous operation at this plant, is well illustrated in Fig. 8. Each set consists of four tubes with three in operation, the fourth one a spare. Each tube is composed of a quartz member about 5 ft. long, around which is formed the heating element, a coil of nichrome or molybdenum wire. About this element a heat insulating jacket of Sil-o-cel is held in place by a galvanized iron jacket. The quartz tube is attached to water-cooled, cast fittings at each end which are provided with connections to the hydrogen supply and exhaust system.

Single phase current is supplied to each tube at 220 volts, a set of three consuming about 50 amp. on tungsten reduction and 30 amp. on molybdenum reduction. This difference is due to necessity of getting 1200 deg. C. on tungsten and 900 deg. C. on molybdenum. Two sets of the old type furnace consume about 3000 cu.ft. of hydrogen per 24 hours.

When starting up with a new charge the heat must be applied very slowly to prevent fusion of the WO_3 powder before the exothermic reaction starts. Should this fusion occur, the reduction would be accomplished only on the surface of the mass.

New Type Reduction Furnace

The Fansteel Products Co. has just completed and placed in operation a four-tube tungsten reduction furnace set of entirely new design and larger than those previously operated. The complete outfit consists of the furnace proper, assembly drawing of which is shown in Fig. 9, the water chest beneath the tubes; three calcium chloride towers about 1 ft. in diameter and 8 ft. high for drying the hydrogen from the furnace; complete pyrometer equipment for noting temperature of hydrogen in the jacket of each tube; three glass tubes packed with absorbent cotton to purify hydrogen; one hydrogen pump oil type, manufactured by C. Crowell, and hydrogen pressure tank; together with complete switchboard and control equipment for the heating coils.

The hydrogen supply enters the annular space between the 3-in. and 1½-in. pipe and is preheated prior to entering the furnace by the exhaust in the 1½-in. pipe as seen in Fig. 9. Passing into the space between the quartz tube and the jacket, it is further heated, and finally enters the main tube, passing out near the point of entrance.

The tube is equipped with an additional preheater coil at the right of the drawing with connection terminals as shown on extreme right. Fig. 10 shows the feed end of the furnace with the hydrogen apparatus in the rear. The picture was taken before all the lower piping connections had been made. Peepholes are evident in the doors. Glass-absorbing tube appears in the background beyond door of rear tube. The whole equipment is excellent in design and shows careful workmanship. The operating record should prove a distinct advance in reduction furnace efficiency.

The gray tungsten powder is removed from the furnace after a period of about 7 hr., when it has been reduced to a high state of purity. Analyses are given under tungstic oxide. This powder is then placed under a hydraulic pressure of 300 tons and formed into a bar

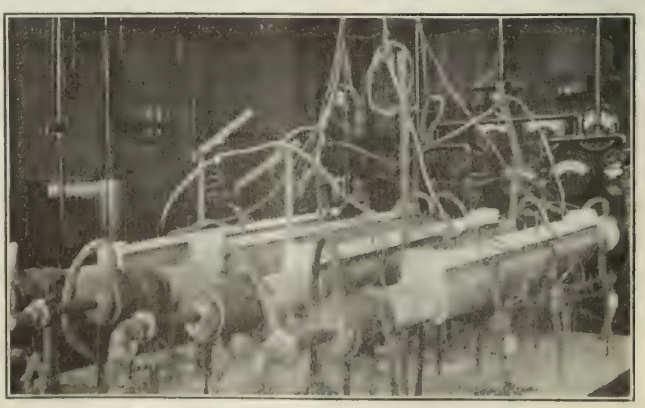

FIG. 8. OLD TYPE REDUCTION FURNACE

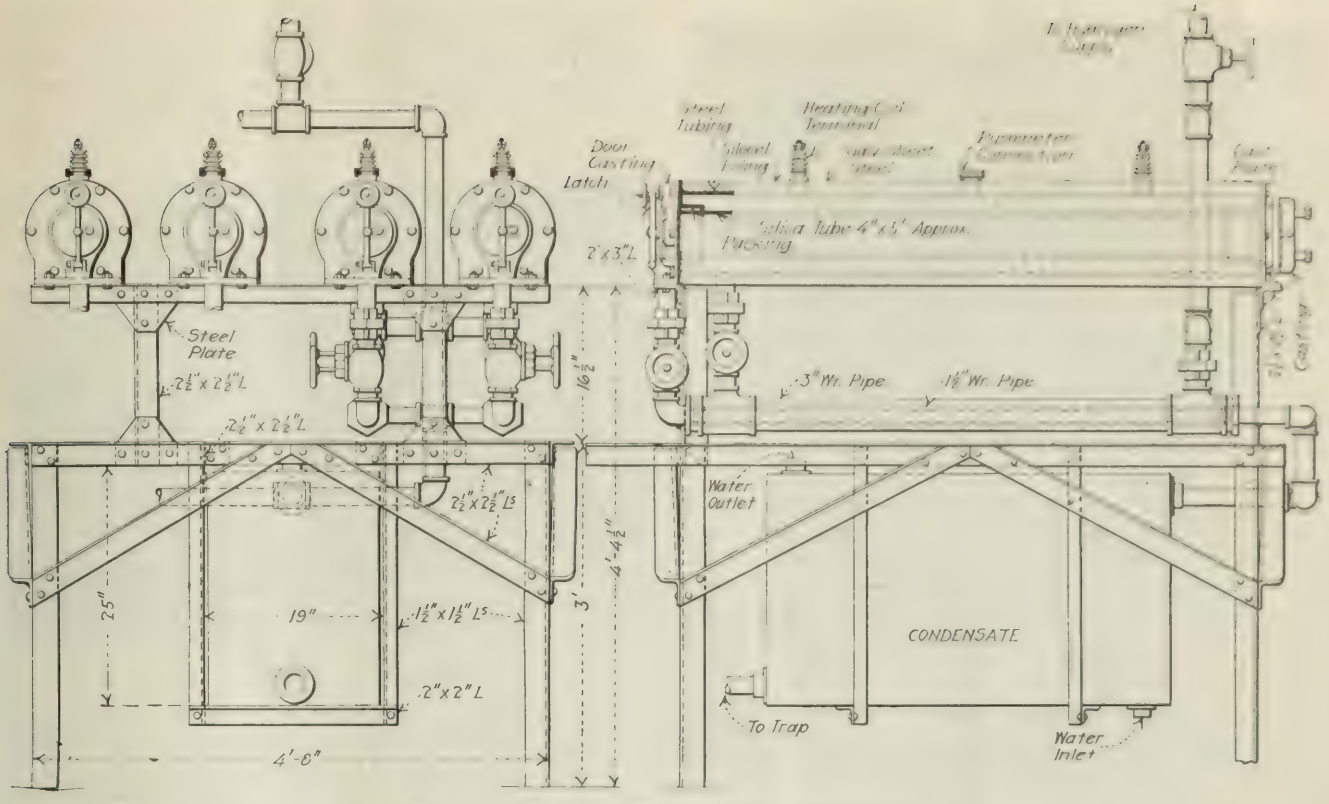

FIG. 9. NEW TYPE OF REDUCTION FURNACE

which might properly be termed cast tungsten. The bars vary in size as desired according to die used. The average bar is 1 in. square and 8 in. long.

Sintering Furnaces

These bars are placed between contacts as shown in the sintering furnace, Fig. 12, where they are subjected to a current of 2750 amp. at 220 volts single phase. The temperature is maintained in an atmosphere of dry hydrogen and the body of the furnace is water cooled. The large bottle on the right contains calcium chloride for drying the hydrogen.

Fig. 11 shows the furnace closed and in operation, while Fig. 12 illustrates a bar just finished and in place in the furnace. This process causes considerable shrinkage in size, as may be noted by comparing with the unsintered bar on the table directly below the one between the contacts.

Swaging and Drawing

The sintered bars are taken to the swaging room, where 14 specially designed furnaces are in operation. Each furnace consists essentially of a refractory tube surrounded by a jacket at a distance from the tube to form an annular space. The hydrogen is introduced into this space, permeates the walls of the refractory alundum and enters the center of the tube where the metal bar is placed. The hydrogen then passes out the opening through which the bar has been placed and burns in contact with the air.

Each furnace is heated, by a coil wrapped around the refractory tube, to a temperature of from 1100 deg. to 1500 deg. C. The fourteen furnaces consume 185 amp. at 220 volts single phase. The alundum tubes burn out in from 3 to 6 weeks, operating at 14 hr. per day.

The bars are heated and one end is drawn in an Excelsior Needle Co. machine appearing on right of furnace (Fig. 13). The opposite end is then placed in the furnace first, heated, and the drawing operation repeated. This continues until the bar is brought down to the required size, either as bar or heavy wire. It is then ready for the market or for cutting into fine contact buttons.

Contact Manufacture

The wheels for cutting tungsten are about 0.016 in. thick, 3 in. in diameter and made of an abrasive material with rubber as a binder. A cooling mixture is continually sprayed over the point of contact during the cutting operation. The small tungsten contact button is attached to the steel screw stud in an interesting manner. Buttons are placed in a jig with a thin sheet of copper on top of each button. Over this the screw studs are inverted so that the copper sheets lie at the surface of contact between tungsten and steel. The

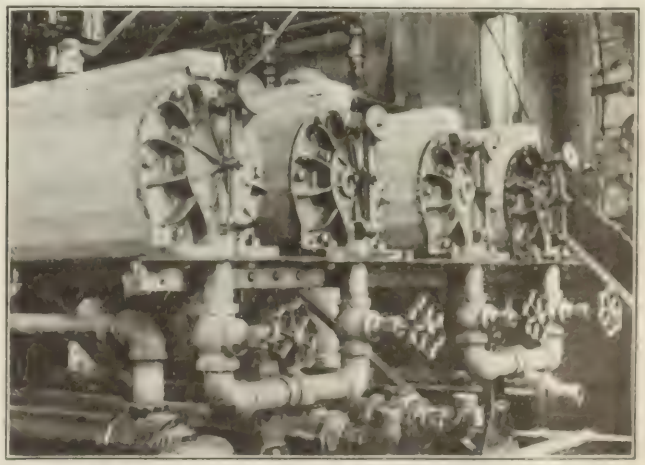

FIG. 10. FEED END OF FURNACE, WITH HYDROGEN APPARATUS IN REAR

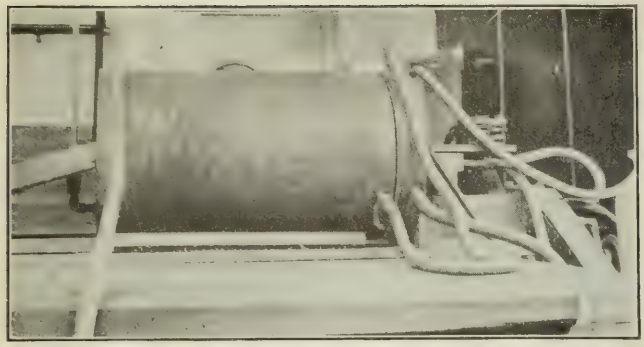

FIG. 11. SINTERING FURNACE CLOSED

whole is then placed in a hydrogen atmosphere furnace battery illustrated in Fig. 14 and of design similar to swaging furnaces.

The temperature is brought up to a point where the copper volatilizes, permeating both the steel and tungsten to a sufficient extent to braze the two firmly. This covers the entire contact with a copper plating, which is removed in a Hanson-Van Winkle deplating bath. The point is then polished on an oiled abrasive wheel and is ready for the market.

Rolling Sheets

The rolling operation is somewhat more difficult and requires expert attention. The swaged bar about $\frac{3}{8}$ in. by $\frac{3}{4}$ in. in section is heated in a small furnace shown in

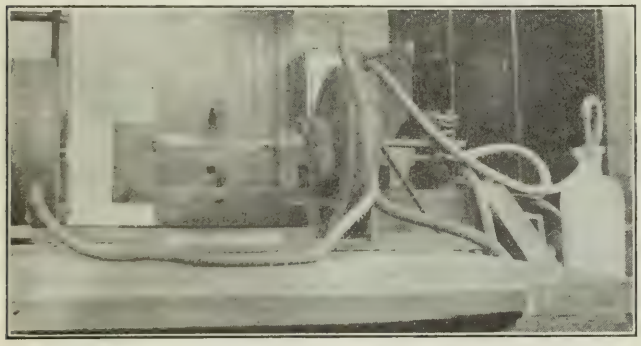

FIG. 12. SINTERING FURNACE OPEN

Fig. 14 to about 1200 deg. to 1400 deg. C. The furnace consumes 45 amp. at 220 volts single phase.

With continued heating and rolling in the preliminary rolls shown in Fig. 15 the bar is brought to a thick strip. As the strip grows thinner care must be exercised during the heat to prevent excess heat resintering the metal. The strip is then removed to finishing rolls and furnace (Fig. 16), where it is brought down to required thickness by continued heating and rolling.

It will be noted in the background of several of these illustrations that a quantity of electrical apparatus is in evidence. All the transformers, furnaces and regulators were designed and made by the Fansteel Products Co. This was necessary owing to the special nature of the work involved.

Properties of Pure Metallic Tungsten

The company produces tungsten wire in round shapes from 0.080 wire up to $\frac{1}{2}$-in. rods and sheets for special purposes as desired. The metal is a pure wrought, ductile, fibrous substance as shown in the foregoing processes. It is rolled into thin sheets and it may be welded at yellow heat. The melting point is about 3080 deg. C. and the specific gravity 18.8.

The tensile strength in a 5-mm. diameter wire is 460,000 lb. per sq.in. and in a 1.2-mm. diameter is 580,000 lb. per sq.in. Rolled sheets have a tensile strength of 500,000 lb. per sq.in. It is not affected by air or water at temperatures below red heat.

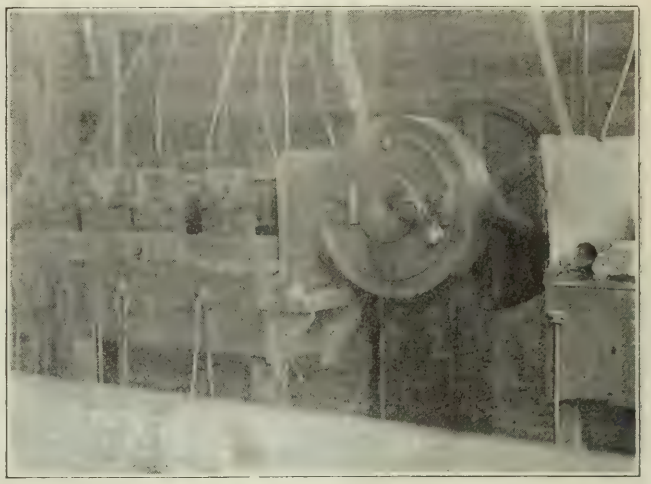

FIG. 13. SWAGING ROOM

While fused nitrates, peroxides, potassium bisulphate, alkali carbonates and caustic alkalis attack the metal, it remains unaffected by solutions of these chemicals.

Reactions With Acids

Sulphuric acid, boiling, dilute, has no effect.

Sulphuric acid, boiling, concentrated, attacks very slowly.

Hydrochloric acid, boiling, concentrated, attacks slowly, but neither strong nor dilute affect at ordinary temperatures.

Nitric acid, concentrated or dilute, has no effect.

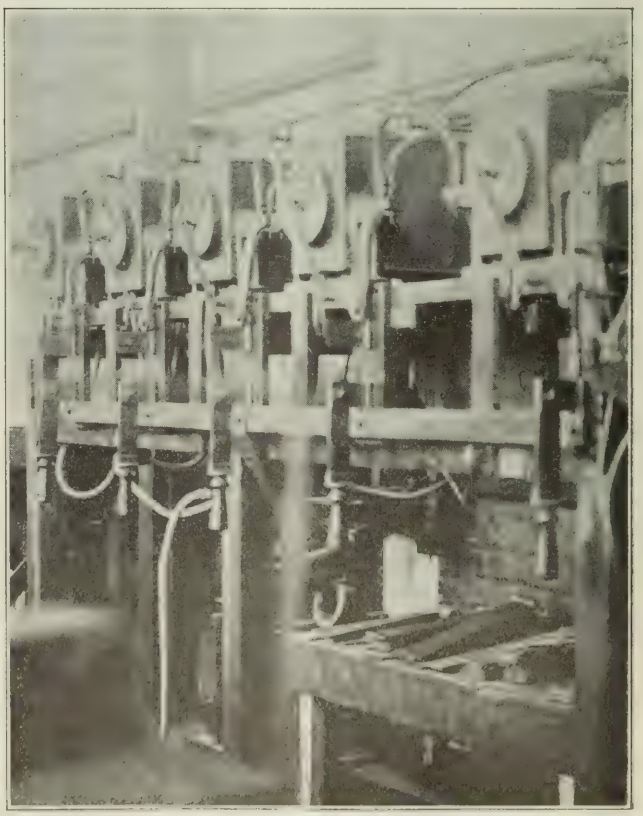

FIG. 14. BRAZING FURNACES

Hydrofluoric, concentrated or dilute, has no effect. Mixture of concentrated HCl and HF attack rapidly.

Uses of Tungsten Aside From Steel Industry

In the electrical industry the use of tungsten is well known, being superior to platinum for contact points on account of its hardness and having a heat conductivity equal to twice that of platinum. It is employed as a target for Röntgen Rays in electrophysical work.

Tungsten bronzes are produced by fusing with pure tin. These are resistant to ordinary acid action.

The dye industry employs tungsten for fireproofing cloth, and as a mordant for silks the salt has the added feature of serving as a weighting material.

In the ceramic industry the tungstic oxide is used for producing yellows in glass and porcelain. (A. Granger, *Compt. rend.*, 1905, pp. 140–935.)

Sodium tungstate decolorizes acetic acid.

In the chemical industry the wire and sheet, being impervious to alkali solutions and to cold and hot acids to the extent described above, should find many practical applications, such as binding cloth on filter wheels, wire gauze for filtering acids; wire mesh for supporting filter cloths; as a support for asbestos packing at Duriron connections; in utensils for nitric and hydrofluoric acids in the laboratory; heating elements in laboratory ovens; as electrodes in certain electrochemical processes; in instrument parts where subjected to fumes from the processes; and as supports for incandescent gas mantles. A thermocouple of tungsten-molybdenum gives an increase in electromotive force with the increase in temperature up to 540 deg. C. and passes through zero millivolts at 1300 deg. C.

Non-Ferrous Alloys

Many alloys useful to the chemical industry have been made, and research will prove that the field in this regard is far from exhausted. Following are some of the better known metal compounds.

Aluminum (metallic) can be hardened with tungsten. Its resistance to oxidization makes it much superior to copper. See "Tungsten, Its Uses and Value," *Mining and Sci. Press*, Dec. 17, 1904.

Partinium ("Tungsten," J. H. Pratt, *Min. Wld.*, Dec. 3, 1904) is an alloy of aluminum and tungsten. It is used by the French in automobile construction because of its lightness and strength.

Sideraphite ("Tungsten," J. H. Pratt, *Min. Wld.*, Dec. 3, 1904) is an alloy containing a large proportion of iron, some nickel, aluminum and copper, and 4 per cent of tungsten. It resembles silver in appearance, is very ductile, malleable and not easily attacked by acids.

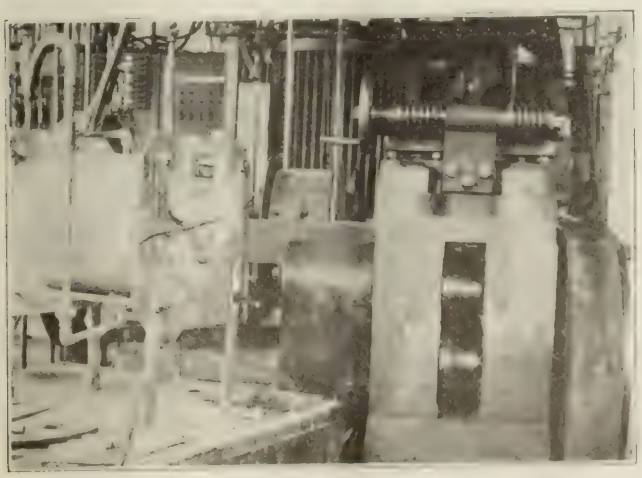

FIG. 15. ROLLING EQUIPMENT. PRELIMINARY ROLLS

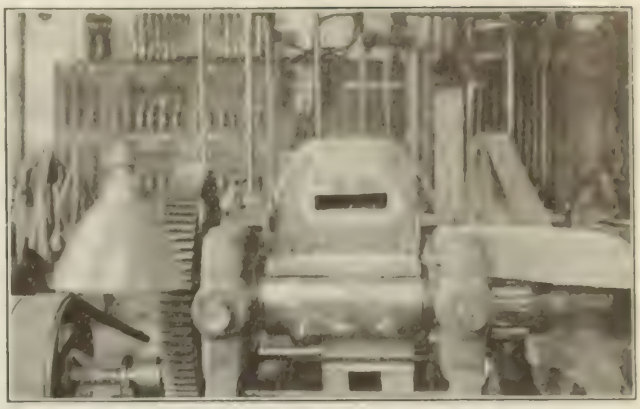

FIG. 16. ROLLING EQUIPMENT. FINISHING ROLLS

Minargent ("Tungsten," J. H. Pratt, *Min. Wld.*, Dec 3, 1904) is an alloy of copper, nickel and tungsten.

Backford, or Britannia metal, is an alloy of copper, tin and tungsten (Hadfield).

The Blackwell Company manufactures a tungsten-nickel alloy which consists of 73 to 75 per cent tungsten, 23 to 25 per cent nickel, and 2 to 2½ per cent iron, 0.75 to 1 per cent carbon, and 0.25 to 0.50 per cent silicon (Pratt).

Platinoid consists of 60 per cent copper, 25 per cent zinc, 14 per cent nickel and 1 to 2 per cent tungsten. It has a high electrical resistance, which does not decrease with heat (Hadfield).

An alloy of tungsten, aluminum and copper is used in the manufacture of propeller blades. (See "Tungsten," Min. Res. U. S. G. S., 1901.)

A series of unnamed alloys has been made by L. P. Hamilton and Edgar F. Smith, *J. Am. Chem. Soc.*, March, 1901, p. 151, which consists of tungsten and copper and aluminum, tungsten-iron-titanium-carbon, and tungsten-iron-columbium-tantalum.

Technical Characteristics

A table of physical and chemical constants for ductile tungsten has been prepared by C. G. Fink of the General Electric Co. as follows:

Density 19.3 to 21.4.
Tensile strength 322 to 427 kg. per sq.mm.
Young's modulus of elasticity is 42,200 kg. per sq.mm. (steel 20,000), i.e., twice that of steel.
Melting point, 3177 deg. C.
Boiling point, 3700 deg. C. (?)
Thermal conductivity 0.35 g. cal. per sq.cm. per sec. per 1 deg. C. (Pt is 0.166). Calculated.
Expansion coefficient 4.3×10^{-6}.
Specific heat 0.0358 (Weiss).
Resistivity (25 deg.) hard, 6.2 microhms per cu.cm.; annealed, 5.0 microhms per cu.cm.
Temperature coefficient of resistance 0.0051 (0-170 deg. C.).
Hardness 4.5 to 8.0 (Mohs scale).
Insoluble in HCl, H_2SO_4, HNO_3, NaOH, KOH (aqueous), $K_2Cr_2O_7 + H_2SO_4$.
Soluble in mixtures of HF and HNO_3 and in fused nitrates, nitrites and peroxides.

Ductile tungsten and molybdenum are available in quantities for commercial consumption; the purity is such as to give metals with properties greatly needed by the chemical and electrochemical markets; new uses are being developed by research; and it would therefore appear that the increase in consumption must of necessity continue.

We wish to acknowledge the courtesy of the Fansteel Products Co. in furnishing facilities and information for the preparation of this article.

Care of the Lumber Pile in Chemical Plants*

THE chemical plants in this country are in a continual state of development, which means that there is always a supply of lumber on hand for repairs and expansion of various projects. As in other lines of industry, this material is usually handled carelessly, where by the expenditure of a small amount of time and money the companies might save considerable sums each year.

One of the simple methods which may be used is the coating of the ends of timber, logs, etc., to prevent splitting and checking, which occurs especially in dry climates, due to the fact that timber dries much more rapidly from the ends than from exposure to the atmosphere on the sides. The rule for end coating in simple terms is that the harder and greener the wood, the more effective must be the coating. Paint is convenient to handle, but is of low effectiveness. White lead is convenient to handle, and is of medium effectiveness. Lorac, a commercial compound, is convenient to handle and also of considerable effectiveness, but the best application is rosin-lampblack, which is inconvenient to handle, but is of high effectiveness.

Rosin-lampblack is made according to the following formula:

Clear grade rosin	60 parts by weight
Lampblack	1 part by weight

The mixture is prepared by melting the rosin but not allowing it to boil or froth, and when in a thoroughly molten condition the lampblack is thoroughly stirred in.

This coating is applied where feasible by dipping the ends of the sticks in the molten mixture to a distance of about one-half inch, which when hardening gives a smooth, shiny coating free from bubbles and about an eighth of an inch thick over the ends. Where large timbers are to be coated the mixture may be applied with a brush or paddle.

If the stock is to be subjected to rough handling which might cause the coating to chip when cool, linseed oil may be added in the proportion of 1 to 15 by weight. This, however, will have a tendency to make the coating excessively soft at temperatures which are higher than 130 deg. F.

STORAGE

Many serious losses from decay in wooden structures are caused by the fact that the timbers used were infected with wood-destroying fungi while in storage. These losses may be greatly reduced by keeping the storage yard in a sanitary condition.

Strong efforts should be made to store the product on well-drained ground removed from possible danger of floods, high tides and standing water. All rotting debris scattered about yards should be collected and burned, no matter whether it be decayed formations and timbers or stored lumber which has become infected. In the case of yards already filled in to considerable depths with sawdust and other woody debris the situation can be improved by heavy surfacing with soil, slag or similar material. Weeds should be cut away from the piles to allow good ventilation.

Solid foundations should never be used for supporting timbers. In damp climates the stock should not be piled less than 18 to 20 inches from the ground. Wood blocking used in direct contact with the wet ground should be protected by the application of creosote or other antiseptic oils or else replaced by concrete, brick or other durable materials. Treated skid timbers would be highly advantageous.

Foundations should be built so that the piles will slope approximately one inch to every foot of length. In most regions lumber should not be close piled in the open, but should be set with crossers at least one inch thick. Lateral spacing is also very desirable. Roofing or cover boards should be placed over the piles and extend for several inches in front and back.

Instead of throwing the crossers about on the ground to become infected with decay, they should be handled carefully, and when not in use piled on sound foundations and kept as dry as possible. If pine saturated with resin or the hard wood of such durable species as white oak or red gum be employed, the danger of possible infection will be greatly decreased.

Where lumber is stored in sheds the necessity of piling higher from the ground is very apparent in many cases. The same remedies apply here as for pile foundations in the open. The sheds should be tightly roofed and the siding should not be run down below the bottom of the foundation sill. Free air circulation is very necessary and only thoroughly dry stock should be stored in close piles under cover.

Should fungous outbreak occur in the storage sheds, the infected foundation timbers should all be torn out and be replaced with wood soaked in an antiseptic solution, or by concrete or brick. In all cases the new foundation should be so constructed as to keep the lumber well off the ground and the soil and timber immediately adjoining the infected areas should be sprayed or painted with an antiseptic solution of water, soluble salt, like sodium chloride, mercury chloride, zinc chloride, or copper sulphate.

*Abstracts from Forest Products Laboratory *Technical Notes*.

New Process for Extracting Wool Grease

A company has been formed in Melbourne for the purpose of exploiting a new process for extracting grease (adeps lanæ, the base of lanolin) from wool, and for the manufacture of special neutral wool-scouring and other soaps. The principal supply of lanolin in pre-war times, it is stated, was drawn from Belgium and Germany. The method of treatment was a trade secret, and no public description is in existence, but it is known that sulphuric acid was used in the final process of refining. In the new Australian process no sulphuric or other acid is used, and the product of the process is wholly animal and pure. A small plant has already been erected and the process tested sufficiently to prove that by it adeps lanæ can be produced in commercial quantities at a very low cost.

(Persons interested can obtain the address of the inventor of the process from the Bureau of Foreign and Domestic Commerce, or its district or co-operative offices, by referring to file No. 40859.)

Filtration and Filters*

By Henry B. Faber

THE importance of filtration in industrial work has during the past three or four years been emphasized particularly in those chemical and industrial lines dealing directly and indirectly with products necessary for war. As we are approaching an era of expansion in all industries, and particularly so in the chemical industry, research and development will call for new methods of manufacture. A note of caution may properly be sounded at this time. Too often the technical man, carried up to too great an altitude by his chemical research, flies too high and neglects to give proper emphasis to the simpler operations, such as filtration, which act as the Scylla and Charybdis to wreck the chemical mariner.

From experience in the handling of a large number and variety of filtering problems, I am inclined to classify them in two major groups.

First, those problems in which the slurries contain suspensions of a colloidal nature. These can hardly be dealt with except by highly specialized forms of apparatus and might even be regarded as a class not applicable to simple filtration. This group will, therefore, be passed over.

Second, those problems in which the solid suspensions may be separated from the liquid by the simple expedient of a filter medium. This latter group may be divided as follows:

Class A, which embraces those slurries in which the suspensions are fine, but not of a colloidal character. This group includes those slurries which contain slow filtering suspensions in large or small bulk, and those slurries which by reason of a relatively small amount of suspended matter require merely clarification.

Class B embraces those slurries containing relatively free filtering suspensions, which permit the liquid content to be separated readily from the solids, where the solid content is of considerable bulk, crystalline or definite in its form.

Class C embraces those slurries which are principally mother liquors, containing relatively large crystals, in which the liquid content can be drained readily, the crystals washed easily, the principal problem being the automatic and easy handling of the solids.

The filtration engineer has designed various types of filtering equipment to be applied to these various groups. A description of their types and their limitations as applied to the various groups will, I believe, be of interest, together with a short sketch of the development of these various types.

Filters for Class A Problems

In class A of group II, in which the suspensions are fine and the slurries slow in filtering, the engineer has two problems confronting him—the problem of large area of filter surface and that of keeping the filter surface clean.

The Filter Press

The filter press is probably the best known type of filter equipment in use. The press consists of a series of shallow frames separated one from another by plates and nested together, forming a series of shallow chambers. Against the plates, which are channeled or scored with shallow galleries, are placed filter cloths, which act as the filtering medium. The slurry to be filtered is pumped into the chambers, the liquid forcing its way through the medium and making its exit by means of the galleries or grooves, leaving the solids deposited upon the medium and gradually filling up the chambers.

Open Tank Leaf Filter

It remained to one George Moore, a metallurgist, to invent a process of filtration in the mining field which has had world-wide acceptance and renown. This process employed the use of filter leaves, operating in an open tank. These leaves were frames of pipe, usually rectangular in shape, over which was sewn filter cloth completely incasing the frames and forming a hollow shallow chamber with ribs spaced equidistant across the face of the leaf for the purpose of preventing the two faces of the cloth from touching. The pipe constituting the lower edge of the frame was perforated. When the leaf was submerged in the slurry to be filtered and suction applied, this suction was translated throughout the entire space within the leaf, causing the liquid to pass rapidly through the cloth, leaving deposited upon the outside surface the solids, in the form of an adhering cake. Many of these leaves were attached to a common header and in this form was called a "basket." The simplicity of this construction permitted the operator to throw into use very large areas of filtering surface at a relatively low cost.

Self-Dumping Filter

At the time of this invention, George Moore anticipated that many problems would be encountered where a greater force than that exerted by a vacuum pull would be necessary to make the separations of solids from liquids. His original patents also called for the incasing of these filter leaves in some simple form of container for use by either suction or pressure. The self-dumping filters, so called, in which the container may be parted from the leaves, shortly made its appearance on the field, and met with wide acceptance in both the mining and industrial world. These filters, in which the basket of filter leaves is completely incased by a container permitting either suction or pressure to be applied to force the liquid through the medium, have a wide application in the many filtering problems of to-day.

Comparison of the Various Types of Filter

To sum up the virtues of these various types, the press, by reason of the fact that the filter cloths can be replaced readily, at a relatively low cost, protects the operator from serious curtailment in his filtering operations by reason of accidental damage to the cloths.

The open tank leaf filter has the advantage of large area of filtering surface and extremely low initial cost.

The self-dumping types of filters, by reason of the fact that they can use pressure as well as suction, have a wider latitude of use, but the same argument applies to them as applies to the open tank leaf type in that time is lost in re-covering the leaves, and repair and renewal are costly.

Filters for Class B Problems

In reference to the handling of problems in class B, viz.: those slurries which are relatively free filtering and build a substantial firm filter cake quickly, the rotary filter is the most desirable type to use.

*Extract from address before the Fifth National Exposition of Chemical Industries, Chicago, Sept. 25, 1919.

The rotary filter made its first appearance in Belgium about 50 years ago or thereabouts, and consisted of a headed barrel rotating about its long axis. The face of the drum was perforated and a filtering medium was stretched around, completely encircling the drum, and held in place by winding cords. This machine was used for the filtration of salts and proved very effective. A gooseneck entered through the head of the drum, dipping down to within an inch of the bottom, and was the means through which suction was applied to the interior of the drum. The drum rotated in a shallow container, dipping into the slurry through an arc of about 40 deg. Later this type of machine was built of sturdy metal construction. The perforated surface was replaced by bars of iron, forming a grating so that the drum had the appearance of a heroic-sized squirrel cage. In all cases, a gooseneck dipping within the drum downward to within a few inches of the bottom served as an exhaust and also to carry the liquid from the inside of the drum.

When rotating, the filter cake, which adhered to the surface of the drum, passed upward and over beyond the zenith, and was removed by means of a scraper.

It remained to the same George Moore who invented the Moore process of filtration to invent a multiple compartment or revolvable filter, which is the rotary filter of today. This filter, instead of being of the squirrel-cage type with a gooseneck outlet, has the peripheral surface of the drum composed of a number of shallow hollow compartments, over which is stretched the filtering medium. Each of these hollow compartments has its own separate pipe line connected to a valve hub by means of which suction or pressure may be applied at will, through any desired arc.

These machines have had wide usage in the mining field for the handling of concentrates and are extensively used in the industrial chemical field, where automatic and continuous filtration is rapidly replacing the batch or intermittent method.

Filters for Class C Problems

In handling slurries of the character mentioned as class C, viz.: crystals from mother liquid or coarse granular suspensions, the centrifugal or draining boards have been widely used.

Rotary Hopper Dewaterer

The rotary filter has failed in many cases by reason of the fact that the solids will form too heavy a cake and will not adhere firmly enough to prevent the cake breaking away from the drum and thickening in the container. The rotary hopper dewaterer is a type of filter machine built especially for this class of work, and consists of a series of elongated hoppers arranged radially about a central axis, each hopper having a filter bed, below which a pipe line connects with the central valve hub, similar in design to that used in the construction of the rotary filter. As the filter beds are set quite a distance below the rim of the hoppers, they form in reality a series of filter trays, revolving slowly about a central axis. The slurry is fed into these trays at a point about 30 deg. from the zenith and dewatered by means of suction as they rotate through an arc of about 40 deg. Suction is then automatically cut off and the product discharged either by gravity or by a puff of air, making the operation continuous and automatic.

Practical Suggestions for the Engineer

Settling Should Precede Filtering

In a great number of the ordinary filtering problems, settling should precede the operation of filtering, or the slurries should be thickened by some means until the amount of suspension has reached the maximum permissible for easy handling. Suspensions will settle at a relatively uniform rate of fall until they thicken to such an extent that they begin to clump. It is usual to consider the rate of settling as uniform until the particles approach one another by a distance less than five times their diameter, at which point the settling rate begins to slow down very rapidly. A simple test that is often made in the laboratory is to permit the slurry to settle freely and plot a curve, showing the widening of the clear supernatant liquor. A point will be noticed in the large majority of problems where the curve shows a marked slowing down of the rate. It is at this point that we find it desirable to complete the separation by filtration. Too often the engineer attempts either to settle completely his slurries or to filter completely his slurries, where a combination of settling and filtering will give a much more efficient operation. This is a general statement, but one which will bear emphasis.

Experimental Filter for Classifying Filtration Problems

The class in which a particular filtration problem belongs may be determined easily by using a small experimental filter leaf constructed as follows:

Bend a small piece of $\frac{1}{8}$-in. brass pipe in the form of a square paddle with sides approximately $3\frac{1}{4}$-in., perforate the lower side and stitch over the frame either unbleached muslin, No. 10 duck or other suitable filtering medium. Strips of wood about the thickness of a lead pencil are inserted between the faces of the cloth in order to prevent collapsing. The filter leaf is now complete. By vacuum rubber pipe 2 or 3 ft. in length, the leaf may be attached to a graduated Woulff bottle, which in turn should be connected up to the suction line. Introduce into a battery jar or large beaker the slurry and submerge the filter leaf. When the suction is turned on, the liquid will pass through the leaf into the Woulff bottle, leaving deposited upon the face of the leaf the solids. Note the time, quantity and character of the liquid constituting the filtrate and the thickness and character of the filter cake produced for the given period of time. The filter leaf with the adhering cake when withdrawn from the slurry may be introduced into a receiver containing wash water, and the wash water drawn through in the same manner as the filtrate. The amount of water necessary to wash the cake can be readily measured, the period of time necessary for washing obtained, and the dryness of the cake determined by allowing the filter leaf with adhering cake after being withdrawn from the wash water to be held suspended in the air until the occluded liquid has been sucked out of its pores. A filter leaf of the above-mentioned size will have approximately one-sixth of a square foot of active filtering surface, and when a ratio is struck between the volume of filtrate or weight of cake to one-sixth of a square foot for the particular period of time employed, the operator can readily calculate the number of square feet of active filtering surface he will need for an installation capable of handling a given quantity of liquid or solid. He will

also be able to determine the amount of wash water, the purity of his cake and moisture content of the latter, which will closely approximate the results he will obtain on a commercial installation.

Deductions From Experimental Tests

From these tests a few general deductions can be made. If it takes a longer time than ten minutes to form a filter cake of at least ¼ in. in thickness, in all probabilities the problem falls into class A, in which are included the filter press, open tank leaf filter and the self-dumping filters. If a firm cake of from ¼ in. to upwards of 2 or 3 in. in thickness can be formed in less than ten minutes, and if the cake frees itself readily from the filter leaf, a rotary filter will very likely handle the problem. In determining the size of the rotary filter by this simple test required for any problem, it must be borne in mind that any point on the peripheral surface on the filter drum will require from one to ten minutes to pass through the full 360 deg. according as the machine makes one r.p.m. or one-tenth r.p.m. Consequently, as frequently less than one-half of the surface of the drum is submerged continuously in the slurry through which it rotates, the requirements for filter surface for continuous operation must be multiplied by approximately two, as less than one-half of the drum is active for cake building. If in making the tests a cake builds so rapidly on the filter leaf and the product is of such a granular nature that in attempting to withdraw the leaf from the slurry the cake will not adhere, but slough off, the centrifugal or the rotary hopper dewaterer will most likely be the type of machine for use.

Suggestions on Washing

Often it is as important to wash the solids as it is to filter them, and a few suggestions along this line may be in order. Irrespective of the type of filter used, the one important factor to provide against is the channeling of the filter cake. In the filter press as well as the self-dumping type it is difficult to provide against a classification of the solids, as the heavier particles will often settle away from the lighter, forming areas of less resistance to the passage of the filtrate. This classification is not met with to any noticeable extent in the open tank leaf type of filter, as the slurries may be kept in constant and thorough agitation during the process of filtration, thus insuring a homogeneous slurry. Consequently, it has been my experience that washing on the open tank leaf type of filter can be accomplished with less wash water and a more thoroughly cleansed product obtained than by either the press or self-dumping type. It seems to be a prevailing custom among engineers to determine the degree of wash that a filter cake has been subjected to by merely testing the wash water coming from the filter. Let me suggest to those who are operating different types of filters, to sample the filter cake itself. Without a doubt, in many instances surprisingly curious results will be obtained. In sampling I do not mean the ordinary grab sample, but a number of samples taken from different parts in the chamber or on the filter leaf. In many cases it will be found that the most astonishing results are due to channeling.

Another important point on the subject of washing is that we do not get the advantages of diffusion to the extent desired by passing our wash water through the cake, and it has been my practice to recommend wherever it is possible where extreme degrees of washing are required with a minimum amount of wash water to discharge the cake after the mother liquor has been replaced to a reasonable extent by wash water, and to churn up or cream the product, thus getting the advantages of diffusion and refilter. I wish to emphasize this method of washing, particularly in the case of the rotary filter, where the period of washing is relatively short, and where much is left to be desired where filtering and washing and automatic discharge are accomplished in one revolution of the filter drum. Most gratifying and surprising results have been obtained on difficult problems of washing where only a sufficient amount of wash water is sprayed upon the cake to replace the mother liquor held by the cake volume for volume, and the cake discharged into some form of agitating tank in which it is creamed up with wash water in sufficient amount to permit of easy handling of the slurry and refiltered.

One other important point before closing the subject of washing is, in dealing with free alkalis, the passage of steam through the cake prior to washing with water will often show very beneficial results.

Importance of Ample Pump Capacity

Why it is that the engineer after recommending the purchase of expensive installation will suddenly take it into his head to economize on the size of the pump, and particularly the size of the pump lines in connection with vacuum filtration, has always been a mystery to me, and yet it is a fact. Allow me to emphasize the need of ample pump capacity. In the filtration of bicarbonate of soda the pump displacement should be from 10 to 15 cu.ft. per minute of free air per sq.ft. of active filtering surface unsubmerged. This amount of free air per sq.ft. decreases rapidly as the porosity of the cake decreases. Carbonate of lime or caustic lime mud from the ordinary soda-lime process requires only from 3 to 5 cu.ft. per unit square area of filtering surface. Another point that the engineer seems to neglect to take into consideration is that short suction lines are preferable to long lines. In one instance I have in mind a 500-ft. suction line, which, although of adequate diameter, failed completely to function, due to its extreme length.

Conclusion

In concluding, allow me to offer a few suggestions to the manufacturers and chemists who have filtering problems to solve.

Filtration is too important a factor in the operation of any plant, where the separation of solids from liquids is a step in the operations, to neglect careful, faithful research on the most practical means of obtaining the separation. These problems cannot be brushed hastily aside or decided hurriedly, but should entail the same thoroughness in research that any technical chemical operation deserves. One of the most important points to emphasize is that in many cases filtration will not be as difficult an operation if more care and attention are given to the form in which the solids appear at the time that filtration is to be attempted. In other words, the chemical reactions should have run their course and the suspensions should have been allowed to form themselves in a physical condition as far as practical, giving the best separation possible in consideration of their nature and crystalline structure.

Recovery of the Nitrogen Contained In Oil Shales

By Louis Simpson

THE question of the economic retorting of oil-yielding shales will be governed by the results of the retort controversy. Whether the oil shale operators of this continent decide to use the "dual purpose" retort of Scotland, with its elaborate attempt to secure as large a yield of nitrogen as may be possible, or whether they will elect to use a "single purpose" retort, which will give them the largest possible yield of high-grade oil, with a small yield of recovered nitrogen, remains to be seen.

It is a pity that the governments, which are so greatly interested, have not as yet seen their way to aid the operators to solve this question. The proof can be gained only at the risk of a considerable expenditure, much of which would be common to all the tests that would have to be made, hence much duplication of expense would be avoided, were any one or more of the governments interested to arrange for comparative trial runs of the several classes of retorts.

Economic Comparison of the "Dual Purpose" and "Single Purpose" Retorts

The first question that has to be decided is whether the "dual purpose" retort or the "single purpose" retort is the more economic when operating under the special conditions existing in different parts of the North American continent.

The "dual purpose" retort has been perfected to educe the oil contained in the shale and at the same time to recover to the greatest possible extent the nitrogen contents of the shale. Owing to certain peculiar conditions present in Scotland years ago, this retort was perfected so that the nitrogen contents might be recovered and were recovered even at the expense of the oil contents. The "single purpose" retort is designed so as to make the utmost recovery of the oil contents and so to make such recovery that the risk of cracking the educed oil is lessened. The "double purpose" retort with its necessary accessories is very expensive to build, while the best examples of "single purpose" retorts can be constructed for very much less money. In Scotland, years ago, when the selling price of oil was very low, when gasoline was almost unsalable and when sulphate of ammonia was selling at prices very much higher than pre-war prices, the operators solved the question, so far as they themselves, then, were concerned, by perfecting the "dual purpose" retort. The operations of this retort in Scotland have certainly proved to be very profitable, but it was the local conditions that made the operations of the retort profitable and given other and widely different local and unfavorable conditions, the results would have been very different. The local conditions now existing on the North American continent are nearly, in every item, the opposite to those existing in Scotland when the "dual purpose" retort was perfected, and on this account it is not safe to accept the results obtained in Scotland from the operations of the "dual purpose" retort as the results likely to be obtained by the use of that retort when operated on this continent.

To make this point clear, the conditions that existed in Scotland and the conditions that exist at many, probably at the majority of locations on this continent, are given in Table I, placed side by side for comparison. It is, however, admitted that locations are to be found where the conditions as stated are not present.

TABLE I—COMPARISON OF CONDITIONS IN SCOTLAND AND IN NORTH AMERICA

	As they existed in Scotland	As existing in North America
Shale, quality	Relatively low in oil contents, but high in nitrogen contents	Relatively high in oil contents, but usually low in nitrogen contents
Oil contents	Sale price low	Sale price much higher
Sulphate	Sale price very high	Pre-war sale price very low
Sulphuric acid	Very low in price delivered	Generally high in price delivered
Bagging	Very low in price delivered	Generally high in price delivered
Machinery and repairs	Low in price delivered	High in price delivered
Wages	Low	Before the war double the scale; now probably four times the old rate
Coal	Low in price delivered	Generally dearer, but in this cost great variations will be found
Market for sulphate	World-wide and therefore in constant demand	Local and therefore seasonal, entailing carrying large stocks
Money	Easily obtainable at low interest	Much dearer

The probable future demand for sulphate of ammonia and its market price are quite obscure. It is known that the manufacture of the products of nitrogen has been immensely increased during the war, while the present consumption is probably not larger than it was before the war, if as large. It is known that much of this increase is from by-product coke ovens, and therefore this source of supply will be persistent in the future, whatever level prices reach. It is known that the remainder of the increase is from processes that obtain the nitrogen from the air, and although it is not certain, it is supposed that these plants will continue to operate.

If sulphate of ammonia and other products of nitrogen are necessary for the welfare of those interested in agriculture, it is not likely that these works, indirectly, in part, paid for by those so interested, will be allowed to lie idle, so that the coke barons and others may charge a high price for a by-product. It is therefore probable that prices will fall to their pre-war level and perhaps lower. Notwithstanding, and in spite of these facts, writers and speakers still persist in claiming that the successful establishment of the oil shale industry depends upon the continued extreme recovery of the nitrogen contained in the shale.

This article is written with the hope of showing that this contention is wrong. Only under special conditions, not often present on this continent, will the utmost possible recovery of the nitrogen in the oil shale become of financial and economic importance and in such rare cases it is possible to add to the approved "single purpose" retort special machinery, especially designed, operated independently from the retort, which will recover the nitrogen as well as if not better than can today be done in the nitrogen recovery section of the "dual purpose" retort.

The axiom still holds good, that by-products should not be manufactured unless the profits accruing upon the money invested in the works and machinery and the working capital necessary for the recovery are equal to or exceed those which would have accrued had the same amount of money been expended in enlarging the output of the original business.

Before a judgment can be arrived at it is necessary that the cost of producing sulphate of ammonia from

nitrogen recovered in the "dual purpose" retort be correctly ascertained.

The late Dr. R. W. Ells, in his report published in 1909 by the Canadian Government on the "Oil Shales of New Brunswick and Nova Scotia," has unintentionally been the cause of much misunderstanding on this point.

On page 35 of his report the cost of the "manufacture of sulphate" is given as 46c. per ton shale. It is not stated to what yield of sulphate per ton shale this figure applies, and as the cost in certain items varies with the yield of sulphate per ton shale, the yield becomes a matter of considerable importance. As, however, Dr. Ells on the previous page had mentioned a shale yielding 77 lb. sulphate per ton, it is presumable that the 46c. was given as the cost of manufacturing 77 lb. of sulphate per ton shale. This cost totals $11.95 per ton of 2000 lb. of sulphate.

Authorities in England have given the cost of manufacturing sulphate from ammonia liquor as being before the war as stated in Table II.

TABLE II—COST TO MANUFACTURE SULPHATE FROM AMMONIA LIQUOR

18 cwt. sulphuric acid at 60 deg. B. at $13.33 per ton	$12.00
3 cwt. lime at $ 2.40 per ton	0.36
Coke	1.10
Bags (containers)	0.86
Repairs, etc	1.10
Labor	3.00
Cost in England before the war	$18.42

This cost is considerably higher than that given by Dr. Ells. Dr. Ells gives no details, so it is not possible to explain this wide (50 per cent) difference, which, however, probably consists in the increased cost of acid (the Scotch purchase their acid at a very low cost, delivered), bags and fuel. Perhaps also Dr. Ells forgot to make any allowance for repairs. In neither estimate are included costs of interest, depreciation or management.

Both Dr. Ells' cost and the English cost were costs before the war, and the cost in both countries would have to be considerably increased to represent today's costs, which may safely be taken to exceed $25 per ton sulphate.

But the $25 cost represents only the cost of manufacture from ammonia liquor to the sulphate. Besides this cost, the cost of recovering the nitrogen (in the form of ammonia) from the shale must be ascertained.

At this point it may be wise to point out that the objective of the investor of money in the oil shale industry is the winning of dollars upon the dollars invested. It is from this viewpoint that the rival retort processes have to be judged. Therefore, to the costs already discussed must be added the extra overhead charges of interest, depreciation and repairs chargeable, owing to the extra cost of the "dual purpose" retort and of its larger exhausters, condensers, pipes and steam boilers, also the extra cost of fuel and water and the extra interest upon working capital required to carry a stock of bags and of sulphate, waiting for shipment to fill the season's orders.

As the making of money is the objective, it is quite legitimate to charge up against the cost of manufacture the interest upon the capital expended, at the rate the money so expended would have earned had it been expended in the recovery of oil from an increased quantity of shale instead of in the recovery of nitrogen and of the manufacture of this nitrogen, so recovered, into sulphate. When this is done, if the total so arrived at is less than the selling price of the sulphate, the manufacture of this sulphate may be considered, but if the total be more, then, and in that case, the manufacture of the sulphate should be avoided.

To show at a glance how local conditions affect the result, Table III has been compiled. The basis upon which this table has been calculated is as follows:

An installation to treat 1000 tons of shale per day of 24 hours, 365 days per year. (1) "Dual purpose" retort, plant with sulphate manufacturing costing $1,200,000. (2) "Single purpose" retort plant without sulphate manufacturing costing $300,000. Depreciation allowed at 15 per cent per annum, interest calculated at different rates from 50 per cent down to 15 per cent (it is believed that some deposits will make it possible for those operating to earn the larger figures and it is not thought that many will expect to earn less than 15 per cent). The returns of sulphate per ton shale are taken from 70 lb. down to 30 lb. By referring to this table and by adding the figure found, where the interest and the per cent of sulphate meet, to the $25 before mentioned, a total will be reached that will indicate nearly the actual cost of the sulphate, when made by the use of the "dual purpose" retort.

TABLE III—COST OF SULPHATE (Overhead and Profit only)

	70 lb. per ton shale	60 lb. per ton shale	50 lb. per ton shale	40 lb. per ton shale	30 lb. per ton shale
50%	$45.79	$53.42	$64.10	$80.13	$106.84
40%	38.73	45.20	54.24	67.80	90.40
30%	31.70	36.98	44.37	55.47	73.96
25%	28.17	32.87	39.44	49.30	65.74
20%	24.65	28.76	34.51	43.14	57.52
15%	21.13	24.66	29.59	36.99	49.32

It is believed that the $25 cost per ton for manufacture, which has to be added to the above, is far too low a present estimate; but using that cost as a basis, the following results are obtained:

Where oil discovery alone would yield only 15 per cent profit on the capital employed and with shale yielding 30 lb. sulphate per ton the cost would be $74.32 per ton; where the oil yields 50 per cent profit, the cost of sulphate would be $131.84 per ton. With 50 lb. shale the low cost would be $54.59 and the high cost $89.10. Seventy lb. sulphate per ton shale is an exceptional return. But to the above total a further charge may have to be added in cases where the capital at command is not sufficient to warrant the erection of a 1000-ton plant using the "dual purpose" retort. In many cases where only 250 tons per day are mined and assembled instead of 1000 tons, it may be assumed that the cost of mining, assembling, and of management will be increased by 25c. per ton of shale. This 25c. per ton shale when retorting shale that yields 30 lb. sulphate of ammonia increases the cost per ton sulphate by no less than $15.

Mention has been made of a possible arrangement by which the nitrogen left in the spent shale can be conveniently recovered. There is no doubt that were the spent shale from a 1000-ton shale unit treated in a revolving horizontal kiln (especially in such cases where the shale contains considerable fixed carbon), it would be possible to recover not only a very high percentage of the nitrogen, but also, if found desirable, the potash contents.

Conclusions

1. The "dual purpose" retort is only of interest when exceptional conditions are present, conditions that are not often met with on the North American continent.

2. The future of the oil shale industry is largely dependent upon the construction of a "single purpose" retort that can be erected at a low cost and which will recover the maximum quantity of oil.

3. It is possible to arrange for a machine which operates independently from the "single purpose" retort, which will recover the contents of nitrogen even more completely than can be done in the nitrogen recovery end of a "dual purpose" retort.

4. Some nitrogen, if desired, can be recovered from the "single purpose" retort, but such recovery is not advisable unless sulphuric acid is obtainable at a low price delivered or unless there be a good local market for the sulphate.

C. P. Zinc for Fixation of the Temperature Scale

By A. O. Ashman

ZINC is probably the most important substance (aside from water) used in the fixation of the temperature scale, its value in this connection being due chiefly to its melting or freezing point, the boiling point being seldom used. The characteristics of this melting point may be stated briefly as follows:

(1) The melting point (419.4 deg. ± 0.1 deg.) as determined by the cooling curve method is extremely sharp and easy to obtain.

(2) It has practically no undercooling effect.

(3) Zinc does not oxidize perceptibly at this temperature, and moreover the oxide is not soluble in the metal, so that the melting point is not affected by oxidation.

(4) Zinc is not easily contaminated by containers commonly used in making melting point determinations, and with due care will last indefinitely.

(5) The position of the melting point is about at the upper limit of usefulness of the copper-constantan couple, and at about the lower limit of the platinum-rhodium couple, the two most commonly used laboratory couples.

Source of Supply

Prior to the war, zinc sufficiently reliable for this work could be obtained from only one source, which in keeping with existing custom was a German concern. Kahlbaum zinc, as well as other metals, was recognized as the standard for this use. Since the opening of the war C.P. zinc has been prepared in this country in a much higher state of purity. This metal is now on the market, and can be obtained in stick form in any desired quantity. It has a constant purity and melting point.

Preparation

The method of preparing C.P. zinc has been published in detail by the Bureau of Standards,[1] and is briefly as follows: The pure zinc is prepared by redistillation of Horsehead spelter. This is carried out in a coal-fired muffle furnace.

Each muffle is filled with approximately 250 lb. of spelter and heated until volatilization begins. The temperature is very carefully regulated by means of a recording pyrometer, as the lead content is dependent almost entirely on the proper temperature, the process being a fractional distillation.

As the zinc is distilled off the lead content of the residue is increased proportionally, and at a certain concentration is carried over with the zinc. When this is the case the charge is drawn and a new one introduced. The burden in the muffles is kept constant by adding spelter equivalent to the weight removed by each draw.

The zinc so prepared is then cast into sticks ¼-in. diameter by 8-in. long, this shape being desirable on account of the ease of breaking without the use of contaminating tools.

The distinguishing characteristics of pure zinc are its extreme softness and beautiful crystallization.

Purity and Effect on Melting Point

Table I, copied from Bureau of Standards Circular No. 66, shows the chemical analysis for Kahlbaum zinc, and zinc produced by the New Jersey Zinc Co.

TABLE I—ANALYSIS OF ZINC SAMPLES

Element Sought	New Jersey Zinc Co.'s Redistilled Horsehead Spelter	C. A. F. Kahlbaum Zinc
Iron	0.005	0.001
Lead	0.0004	0.021
Cadmium	0.0018	0.021
Arsenic	Trace	Trace
Antimony	Not detected	Not detected
Tin	Not detected	Not detected
Sulphur	Trace	Trace
Zinc by difference	99.993	99.957
Total impurities	0.007	0.043
Melting point	419.44°C.	419.30°C.

Wardner and Burgess[2] have found differences of 2.5 deg. C. in the melting points of zinc obtained from different sources. Unfortunately, however, corresponding chemical analyses are not given.

Kreisinger and Barkley[3] point out that metals obtained for this work from chemical supply houses melt at from 2 to 5 deg. lower than corresponding Kahlbaum pure metals.

It is seen from the table that the difference in melting point is 0.14 deg. C. Assuming this is a function only of the impurities present, a difference of less than 0.03 per cent impurities in the zinc will change the melting point by 0.1 deg. C.

In view of the extreme purity of the New Jersey Zinc Co.'s zinc and constancy of the product, we believe that it would be well worth while for the Bureau of Standards to re-determine the freezing point, thereby fixing the temperature scale with an accuracy of at least ± 0.05 deg. and probably 0.01 deg. at that point instead of ± 0.1, as at present.

The methods used in making primary calibrations are well known[4] and will not be given here. It is sufficient to say that the determination of the freezing point is free from experimental difficulties, such as oxidization, contamination, etc. The freezing point of zinc is more sharply defined than that of any other substance used for this purpose, and is probably the easiest of all fixed points to reproduce.

Melting Point Methods at High Temperatures—I*

A Description of the Determination of Melting Points of Metals, Alloys, Salts and Refractory Materials by the Use of Thermo-Electric, Resistance and Optical Pyrometers

By LEO I. DANA and PAUL D. FOOTE

Introduction

THE determination of a melting or freezing point, whether for a physical or physicochemical purpose, resolves itself into the measurement of a temperature under particular conditions and with appropriate technique. The accuracy and ease with which melting points at high temperatures may be determined are due to the comparatively recent developments in pyrometry, electric furnace construction and refractory materials.

The general classes of substances considered are metals, alloys, salts and refractory materials. For the temperature measurements, thermo-electric, resistance and optical pyrometers are employed, depending upon the temperature range and other controlling conditions.

The melting or freezing point of a pure crystalline substance is defined as the temperature at which the solid phase can remain in equilibrium with the liquid phase at normal atmospheric pressure. The effect of pressure is ordinarily insignificant; it is only when the pressure reaches many atmospheres that any change in the melting or freezing point can be readily detected. At the melting point there is a discontinuous change of a number of the physical properties of a material, e. g., thermal conductivity, electrical resistivity, specific volume, etc. In general, alloys, excepting eutectoids, mixtures of refractory oxides and materials with impurities, do not have a definite melting point, but become liquid gradually; that is, they melt over a temperature interval and consequently are considered as having a "melting range."

I. Use of Thermo-Electric Pyrometers

Pure Materials

General Discussion. The experimental arrangement of this method consists of a crucible containing the substance in which a thermocouple, either protected or unprotected, is centrally inserted. The crucible is placed in a uniformly heated portion of an electric furnace. On account of cleanliness, clarity of the atmosphere and preciseness of control, electric resistance furnaces are preferable to gas- or fuel-fired furnaces for accurate melting point determination. When a melting or freezing point is to be observed, the temperature of the furnace is gradually raised or lowered and the temperature as indicated by the thermocouple is noted at frequent and preferably uniform intervals of time. If all conditions were ideal the temperature of the charge would remain constant during melting or freezing. Thus the temperature-time curve would be characterized by a straight line exactly parallel to the axis of time and by a discontinuous change of slope at either end of the line marking the beginning and ending of the period of melting or freezing. Actually, however, the change of state shown by the curve, even for pure materials, is not sudden, but more or less gradual. Only a part of the freezing curve will be flat, and the melting curve usually possesses greater obliquity than the freezing curve. For this reason freezing point determinations are usually more reliable and are employed whenever possible, although the temperature thus obtained is frequently called the melting point, to which it is numerically equivalent.

The reasons for obliquity, and for its existence to a greater degree in the melting curves, have been discussed in detail by White.[1] On heating, the furnace walls are hotter than the crucible and hence heat flows from the furnace to the crucible. When a layer of the charge near the wall of the crucible reaches the melting point, the heat absorbed by the charge goes to supply that necessary for the latent heat of fusion, and the temperature of the outside layer tends to remain fairly constant. The thermocouple measures the temperature of the solid metal in the center of the charge and when thus surrounded by an isothermal layer the rate at which the inside temperature increases is greatly diminished, resulting in a rounding off of the temperature-time curve. As the isothermal layer progresses inward the temperature of the couple slowly rises until the material immediately surrounding it begins to melt, when a condition of stationary temperature is maintained for a short time during which the thermocouple reading gives the true melting point. While the center of the charge is melting, however, the temperature of the outer layer of material in the crucible rises very rapidly and a large temperature gradient is established between the outside and center. The resulting rapid flow of heat to the center of the crucible accelerates the melting and, if the layer of remaining solid metal is unequally distributed about the couple, tends to increase the temperature readings and cause another rounding off of the temperature-time curve. The apparent degree of obliquity found near the beginning and end of the melting period depends considerably on the sensitivity of the temperature measurements and scale of plotting. Thus highly accurate data obtained with a precision potentiometer may be plotted on so large a temperature scale that the curve may appear quite oblique, while the same data replotted on a less-extended scale appear fairly flat. Aside from this, however, the degree of obliquity varies according to the factors controlling the differences in temperature within the charge, such as dimensions and thermal properties, rate of heat supply, etc. If the solid metal could be stirred during a melting point determination the temperature gradients could be diminished, but even with powdered materials where

*Part II will be published in the Jan. 14 issue.

[1] White, "Melting Point Determinations," *Am. J. Sci.*, vol. 28, p. 453; 1909.

stirring is possible it is not convenient and does not appear to be very satisfactory. The larger the diameter of the charge, the faster the rate of heating, the smaller the diffusivity and the less the latent heat of fusion the greater will be the tendency to obliquity. The obliquity may be decreased by slow heating and by using a charge of fairly small diameter. The protection tubes of the thermocouple should be small, of thin wall and should be deeply immersed in the charge. With metals the obliquity is not so great as with salts on account of their higher heat diffusivity and latent heat of fusion; in fact, for most cases the obliquity is of negligible importance with pure metals. But with salts and certain refractory materials, unless special care is taken, the obliquity may be so great as to obscure almost completely the true melting phenomenon.

On cooling, the crucible is hotter than the furnace walls, and heat flows from the crucible to the furnace. The outer layer of the charge solidifies first and during freezing acts as an isothermal layer, thus decreasing the temperature differences between the center and outside of the charge. The rate at which the temperature of the couple falls decreases, causing a rounding off of the first part of the temperature-time curve. While the center of the charge is freezing the outside is completely frozen and rapidly falls in temperature, increasing the temperature gradient and the outward flow of heat, and hence the latter part of the freezing is accelerated.

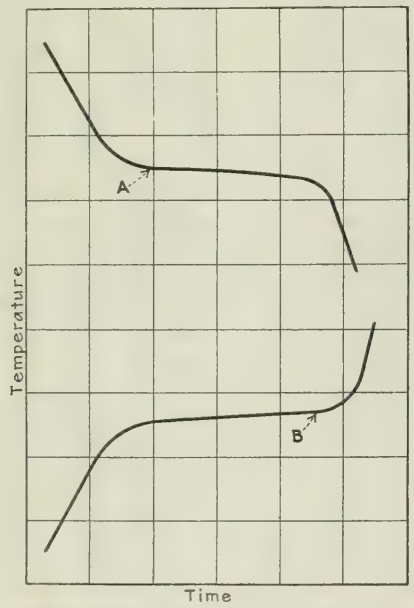

FIG. 1. OBLIQUE FREEZING AND MELTING CURVES

The first part of the approximately flat portion of the curve for freezing corresponds to the true freezing point, and the latter part of the approximately flat portion of the curve for melting corresponds to the true melting point. The same precautions of high narrow charges, narrow protecting tubes, sufficient depth of immersion and small thermocouple wires apply to both cases.

In general the freezing curves are more sharply defined than the melting curves. A liquid cooling and subject to convection currents is likely to possess a more uniform temperature distribution than a solid on heating. Furthermore, the freezing point is chosen at a time immediately following a period of small temperature gradients, while the melting point must be chosen

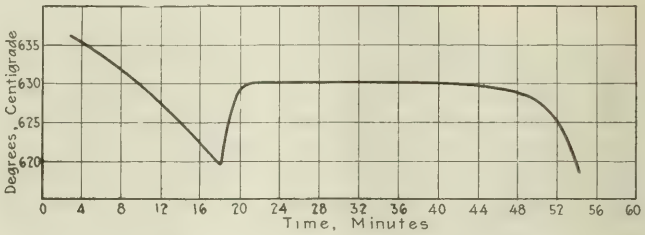

FIG. 2. FREEZING CURVE OF ANTIMONY SHOWING UNDERCOOLING

near the end of the period of melting, when there is possibility of temperature non-uniformity. A further factor of importance is the constancy of heat supply. On cooling with a furnace well insulated, the freeze may extend over a considerable time with all power supply shut off. The furnace thus acquires a uniform rate of cooling. In heating, however, the effect of slight variations in the power supply may alter the true character of the melting curve. Fig. 1 shows a freezing and a melting curve in which considerable obliquity is present. The true temperature for freezing is obtained by extrapolating the straight portion of the freezing curve and noting at what temperature *A* the continued straight line deviates from the observed curve. The melting point *B* is similarly obtained from the melting curve. The first part of the freezing curve and the last part of the melting curve determine these two temperatures, as stated above.

It is impossible to obtain satisfactory freezing curves with certain materials such as silicates on account of extremely slow crystallization, and the melting curves, even though frequently poorly defined, must be employed. The phenomenon of surfusion or supercooling is well illustrated by water, which may be cooled to —30 deg. C. without freezing. Surfusion is due to conditions which do not favor the attainment of equilibrium between the solid and liquid phases at the true freezing point. The conditions tending to produce equilibrium and the elimination of surfusion are slow cooling, stirring of the liquid and the presence of nuclei which serve as centers of crystallization. When a supercooled liquid freezes, it crystallizes very rapidly and the temperature rises to the true freezing point provided the supercooling has not proceeded too far. The

TABLE I.

Laboratory	Crucible Dimensions, All in Cm.				Charge Dimensions		Protection Tube		Distance from Bottoms of Charge to Protection Tubes
	Inside		Outside		Diameter	Height	Diameter		
	Diameter	Height	Diameter	Height			Outside	Inside	
Bureau of Standards	7	15	8.5	16	7.0	11	1.0	0.8	1.0
Geophysical	2.7	8	3.7	10	2.7	5	0.8	0.5	0.5
Bureau of Standards	1.2	3	2.0	3.5	1.2	2	0.15	0.1	0.3

subsequent freezing takes place in a normal manner. Surfusion in most metals seldom exceeds 0.1 or 0.2 deg. C., but in the case of antimony it is very marked and may amount to 30 deg., depending upon the rate of cooling, as shown by Fig. 2. Supercooling also occurs in alloys, especially in eutectics. While the contrary phenomenon of superheating is negligible with pure metals, it may become of importance with alloys, particularly in allotropic transformation and with salts and silicates.

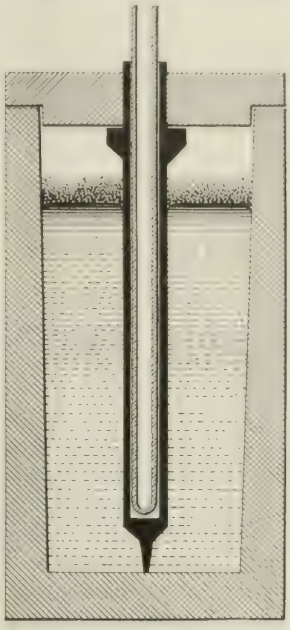

FIG. 3. GRAPHITE SHEATH FOR PROTECTION OF PORCELAIN TUBE IN ALUMINUM

Precision Work With Pure Metals. The primary method for the standardization of thermocouples consists in determining the e.m.f. developed by the couple at the freezing points of several very pure metals. The metals so employed are those the freezing points of which have been accepted as fixed points on the high temperature scale, e. g., tin, cadmium, zinc, antimony, aluminum, silver, gold, copper, etc. For this work and for the reverse problem of accurately determining the freezing points of metals and alloys the greatest precautions against contamination of the couple and the metal are required. Precision work at high temperatures requires the use of homogeneous platinum-90 per cent platinum, 10 per cent rhodium couples. The diameter of the wire usually employed is 0.5 or 0.6 mm., but for certain special purposes wires of 0.1 mm. are useful.

Crucibles and Protecting Tubes. Of all crucible materials Acheson graphite has the greatest utility. It is very pure, can be machined into any desired shape, and is not attacked by most of the common metals. At high temperatures the gases formed from its oxidation provide the reducing atmosphere necessary for the protection of the metal. Table I illustrates sizes of graphite crucibles which have been used in various investigations. For resistance thermometry the largest size shown is necessary, but for general work the intermediate size shown is recommended. In this case a smaller protecting tube is desirable, for example, one with an outside diameter of 5 mm.

Some metals, such as nickel and iron, combined with graphite, and certain other metals also should not be heated under the reducing conditions present with graphite. Crucibles of magnesia, alumina or mixtures of the two are suitable for iron and nickel. Porcelain crucibles may be used for many of the metals, but there is always danger of these cracking when the metal melts or freezes.

Up to 500 deg. C. protection tubes and insulating tubes for the couple made of pyrex glass are useful. From 500 to 1100 deg. C., lower grade porcelain glazed on the outside only or fused quartz are satisfactory. Above 1100 deg. C. tubes having a composition approximating that of sillimanite, Al_2O_3, SiO_2, are recommended.[2]

Porcelain tubes, or crucibles, or any material containing silica cannot be used in contact with aluminum, as the silica is readily attacked. Aluminum may be melted in a graphite crucible and the porcelain protecting tube itself may be protected by a very thin sheath of graphite. Fig. 3 illustrates one convenient manner on which the sheath may be mounted in the crucible. The sheath is held down in the metal by the weight of the cover and is allowed to remain in the crucible after the aluminum is frozen. The thermocouple protecting tube fits tightly inside the sheath. At present there is no satisfactory protecting tube for nickel. This material and its alloys can be best studied by optical methods.

Table of Melting Points. Table II lists the more common metals the melting points of which can be used for the standardization of thermocouples by the crucible method.

[2]Such porcelain is made by Stupakoff Laboratories, Pittsburgh, under the trade name "Usalite," and by Charles Engelhard Co., New York, under the trade name "Impervite."

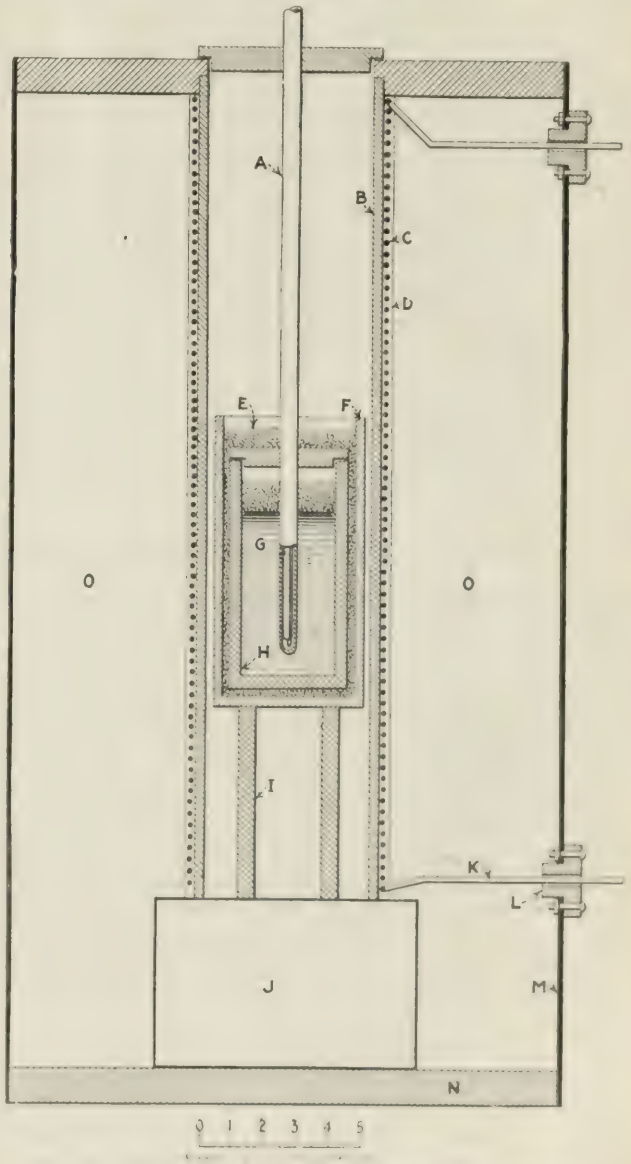

FIG. 4. MELTING POINT FURNACE FOR METALS AND ALLOYS

TABLE II.

Metal	Melting Point, Deg. C.	Crucible Material	Atmosphere
Tin	231.9	Graphite, porcelain or pyrex glass.	Reducing, neutral or air
Bismuth	271	Graphite, porcelain or pyrex glass.	Reducing or neutral
Cadmium	320.9	Graphite, porcelain or pyrex glass.	Reducing or neutral
Lead	327.4	Graphite	Reducing or neutral
Zinc	419.4	Graphite	Reducing or neutral
Antimony	630.0	Graphite	Reducing, CO
Aluminum	658.7	Graphite	Reducing, CO
Silver	960.5	Graphite	Reducing, CO
Gold	1063.0	Graphite	Reducing, neutral or air
Copper	1083.0	Graphite	Reducing, CO
Nickel	1452	MgO, Al_2O_3 or mixtures of the two	H_2, N_2, or vacuum

The surface of the metal should be covered with a layer of powdered or flaked graphite, and the crucible should be provided with a cover having a hole through which the thermocouple tube is inserted. Under no circumstances should graphite be exposed to an air current above 500 deg. C., as it readily oxidizes and crumbles away. The furnace should be tightly closed at the bottom and no larger openings exposed at the top than

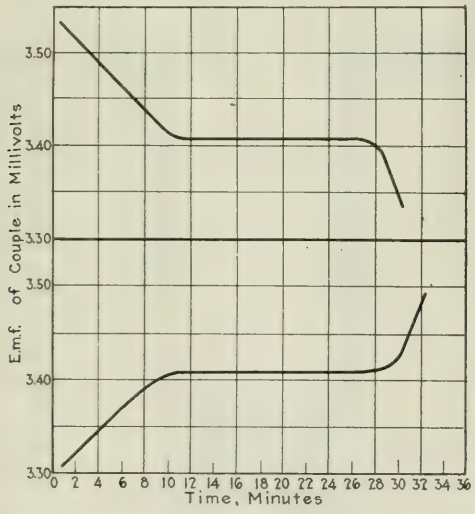

FIG. 5. FREEZING AND MELTING CURVES OF PURE ZINC

absolutely necessary. When fairly small graphite crucibles are employed it is frequently desirable to use a larger outside crucible of porcelain and fill the space between the two crucibles with graphite powder.

Construction of Furnace. Fig. 4 shows the construction of a furnace using crucibles of the intermediate size given in Table I for operation up to 1100 deg. C. The graphite crucible *H* containing the metal *G* and the pyrometer tube *A* rest in a porcelain crucible *F* and are completely covered by powdered graphite *E*. The porcelain crucible is supported in the alundum tube *D*. The heater tube is of alundum, R. A. 98, length 25 cm., inside diameter 5 cm. and wall thickness 3 mm. This is preferably corrugated on the outside and is wound with 60 to 80 turns of No. 14 "Chromel A" wire, *C*, to the ends of which are welded the lead in terminals *K* of No. 10 Chromel. The alundum tubes *B* and *D* rest on a good-conducting fire brick about 5 x 8 x 8 cm. The shell *M*, 32 cm. high, is of sheet iron or monel metal painted with aluminum paint. The ends of the shell are closed by impregnated asbestos boards *N*, 1 cm. thick and 17 cm. in diameter. The annular space *O* is packed with sil-o-cel powder. The lead-in wires are insulated from the metal shell by asbestos board or steatite bushings. The furnace in series with a rheostat for control may be operated on 110 volts and consumes about 1 kw. at 1100 deg. C.

Larger furnaces are required for the large crucibles described in Table I. Such a furnace may be constructed from the following stock material: Alundum tube, R. A.

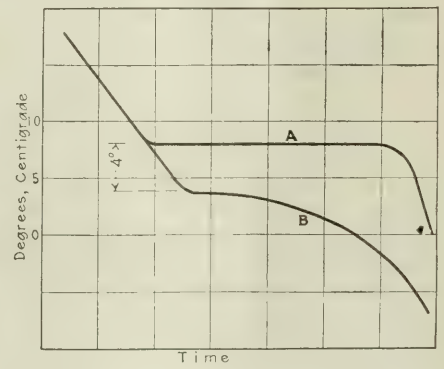

FIG. 6. FREEZING CURVES WITHOUT AND WITH IMPURITY

98, length 45 cm., inside diameter 8 cm., wall thickness 6 mm. Chromel A winding No. 5 wire; 60 turns separated by asbestos cord and covered over with a layer of alundum cement. Diameter of shell 36 cm.; height of shell, 60 cm.; sil-o-cel powder insulation, general construction similar to Fig. 4. Power required for 1100 deg. C. about 55 amp. at 60 volts. Using the large crucibles a freeze of copper with all power off extends over a period of about 20 minutes.

General Precautions. In order to melt for the first time a metal which is in small pieces, the graphite crucible, filled with the material, fitted with a cover having a hole in which the thermocouple fits tightly, and surrounded by powdered graphite, is slowly heated. If convenient CO or N_2 may be passed into the furnace, but CO_2 should not be used. The surface of the metal should not be covered with graphite at first, as it may filter into the interior and become imprisoned there. When the metal has been melted, however, the graphite

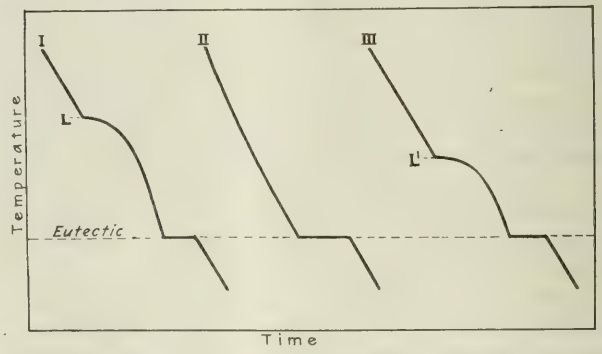

FIG. 7. FREEZING CURVES OF SIMPLE EUTECTIC ALLOYS

layer on the surface is quite desirable. With the exception of antimony, which should be stirred just as the freezing point is reached to reduce supercooling, it is not advisable to stir the molten metals, as pockets of graphite are thereby formed.

If there is doubt concerning the proper depth of immersion, several determinations should be made at different depths until a position is found where a slight variation does not affect the temperature measurement.

The pyrometer tube may be allowed to remain in the metal for a few degrees below the freezing point without breaking, and if it cannot be removed then, the metal should be immediately remelted.

A uniform rate of cooling of about 2 deg. C. per minute from 10 deg. C. above the melting point is satisfactory for a freezing point determination. The values obtained from melting and freezing curves should agree to from 0.1 to 0.01 deg. for pure metals, and the curves should have a flat portion extending over at least 10 minutes. If the curve is not fairly flat, the metal is likely impure and hence possesses a melting range instead of a true melting point. Fig. 5 illustrates an observed freezing and melting curve for zinc. The freezing curve is constant to 0.05 deg. C. for a period of 15 minutes and the melting curve for 10 minutes. The obliquity in the latter part of the melting curve amounts to 0.1 deg. in 6 minutes.

Metals With Impurities, and Alloys

An impurity in a metal usually lowers the melting point and produces obliquity in the melting and freezing curves, the magnitude of both of these effects increasing, within limits, as the amount of impurity is increased. Assuming the amount of impurity is small and that an ideal solution with the metal in the liquid state is formed, the lowering of the freezing point Δt may be expressed approximately by the Raoult-Van't Hoff equation:

$$\triangle t = \frac{R\Theta^2}{L} \cdot \frac{N_1}{N}$$

in which R = 1.99, Θ = absolute temperature of the freezing point of the pure metal, L = molar latent heat of fusion of the pure metal, N_1 = number of mols of impurity, and N = number of mols of pure metal. In Fig. 6, *A* represents the freezing curve of a pure substance and *B* the curve obtained when an impurity is present. The lowering of the freezing point is 4 deg. C., an amount readily caused by a few tenths of 1 per cent of an impurity at about 800 deg. C. In general, the above equation for freezing point lowering holds only for an impurity which forms the simplest type of eutectic alloy with the pure metal. Evidently it cannot be applicable to those impurities which are wholly or partly soluble in the metal in the solid state, that is, which form solid solutions, for in some of these cases the melting point is raised by the addition of the impurity, as for example nickel added to copper.

For most of the common metals the oxide is insoluble in the pure metal, but with copper this is not the case, and special care must be taken, preferably by the maintenance of a strongly reducing atmosphere, to avoid the formations of cuprous oxide, Cu_2O. This oxide forms a eutectic with copper saturating it at 3.45 per cent of Cu_2O or 0.395 per cent of oxygen by weight, and freezing at 1063 deg. C. As an example of the application of the above equation, the freezing point lowering of copper at the eutectic, considering the Cu_2O as the dissolved impurity, will be calculated.

$$\triangle t = \frac{R\Theta^2}{L} \cdot \frac{N_1}{N} = \frac{2\ (1083 + 273)^2\ (2.19)}{(63.6)\ (43.3)\ (143)}$$

$$\triangle t = 20.4 \text{ deg. } C.$$

The lowering found experimentally is 20.0 deg. C.

If the copper contains only a small amount of the oxide, the first solidification begins slightly below the melting point of pure copper and crystals of copper separate from the solution. The concentration of the dissolved impurity Cu_2O accordingly increases, so that the freezing point of the remaining part of the solution is still lower. The pure copper will continue to separate from the liquid at a gradually decreasing temperature until the solution becomes saturated with Cu_2O. This results in rounding or obliquity of the cooling curve. When the remaining solution is saturated, both the Cu and the Cu_2O solidify together, at a constant temperature, as a eutectic mixture. At this point a halt occurs in the cooling curve, the magnitude of which depends upon the amount of the eutectic present. The effect of a small amount of Cu_2O will escape notice in an ordinary melting point determination, but if considerable oxide is present the freezing curve shows the two retardations, one below 1083 deg. and the other at 1063 deg. C. Observation continued through the latter point may serve as a rough criterion of the purity of copper suspected of contamination by its oxide. The obliquity of the curve also may be an indication of impurity. If a copper wire is slowly heated in air, the melting usually

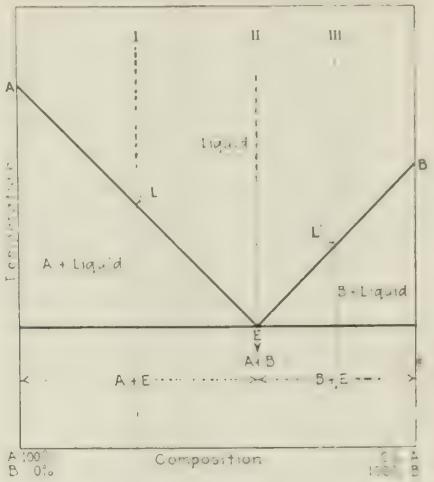

FIG. 8. TEMPERATURE-COMPOSITION DIAGRAM OF SIMPLE EUTECTIC ALLOY

begins at the eutectic point 1063 deg. instead of at 1083 deg. C.

Oxygen dissolves in silver and may lower the melting point as much as 5 deg. C. if the silver is heated in air.

An alloy may be considered as a metal containing large proportions of one or more impurities. Let us consider the simplest case of an alloy of two metals *A* and *B* which are mutually soluble when liquid and insoluble when solid. If *A* first begins to separate from the solution, the remaining liquid becomes richer in *B*, and as shown above, this part of the freezing curve gradually changes in slope as illustrated by Fig. 7, Curve I, L. As the temperature is lowered the solution finally becomes saturated with *B*, and *A* and *B* crystallize together as a eutectic, shown in Fig. 7 by the lower flat portion of the cooling curve. The alloy accordingly has a melting or freezing range extending from the temperature at which separation of *A* first begins to the temperature at which the eutectic mixture solidifies. If the original composition of the alloy is the eutectic mixture, there exists a true melting point as shown in Fig. 7, II, and not a melting range.

The general form of the temperature-composition diagram of the simple binary alloy described above is illustrated by Fig. 8. The curves I, II and III, of Fig. 7 show

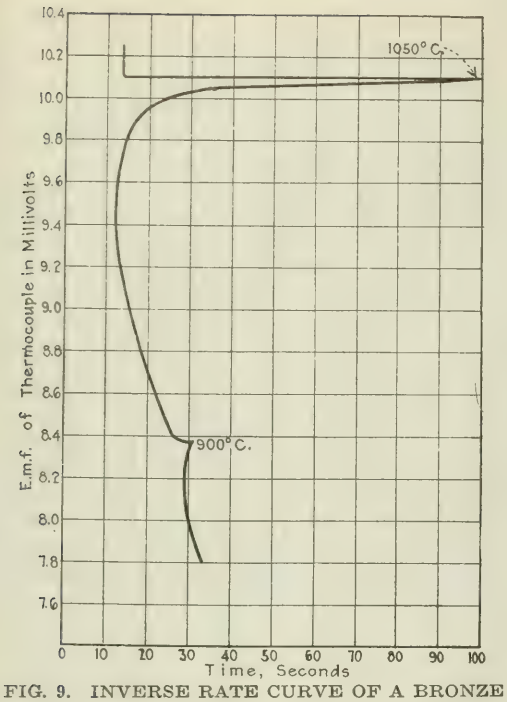

FIG. 9. INVERSE RATE CURVE OF A BRONZE

the form of the cooling curves obtained with the alloys of compositions I, II and III of Fig. 8.

Often a binary alloy exhibits two halts in the melting and freezing curves, one oblique and one flat, or both oblique. Furthermore, other complications may arise, such as the formation of solid solutions, compounds and allotropic transformations accompanied by heat changes which require more sensitive methods of detection than by a simple cooling curve. In general the larger the melting range in a binary alloy the more difficult it becomes to locate the lower transformation point because of the small amount of crystallization per degree drop in temperature and the resulting small heat effect. The same general details for melting point of pure metals apply to alloys. The eutectic alloy Ag-Cu, 71.9 per cent Ag, 28.1 per cent Cu, melts at 779 deg. C. and is useful as a standardization temperature for thermocouples.

For alloys having a large melting range, accurate control of the rate of heating and cooling is essential. Automatic control of the rate may be obtained by a salt water rheostat as applied by Burgess and Crowe,[3] or an automatic magnetic control system may be installed. Scott and Freeman[4] describe a modified Rosenhain furnace for critical point work. This consists of a vertical tube furnace, with a uniform temperature gradient, through which the material is automatically moved at a definite rate.

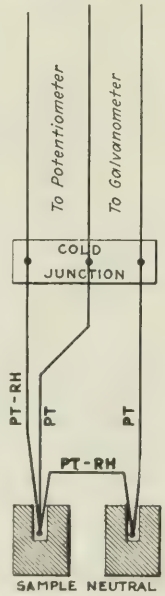

FIG. 10 DIAGRAMMATIC REPRESENTATION OF DIFFERENTIAL METHOD

If the ordinary temperature-time curve does not give evidence of a change of state at the beginning or end of a melting range or at a transformation point, the more sensitive means of detection, such as the inverse-rate method and differential method, may be employed. The former consists in determining the time required for the specimen to fall a definite temperature interval, and in plotting this time against the temperature. The experimental arrangements are the same as for the ordinary time method, except that the time must be measured more accurately. Merica[5] has described a device consisting of two stop watches, one of which is stopped and started at the end of each time interval. Fig. 9 shows an inverse rate curve through the melting range of a bronze. The lower transformation at 900 deg. C. could not be detected by the ordinary temperature-time method.

The differential method is still more sensitive to small thermal changes. This consists in measuring the temperature differences between the material in which the transformation takes place and a neutral body having no transformation points in the same temperature interval, such as platinum or nickel, and plotting this difference against the temperature of the material. Two thermocouples are employed as illustrated by Fig. 10, one a differential couple and the other an ordinary couple which measures the temperature of the sample under investigation. By use of a sensitive galvanometer with the differential couple, extremely minute thermal transformations may be easily detected. Slight variations in the rate of heating produce no noticeable effect.

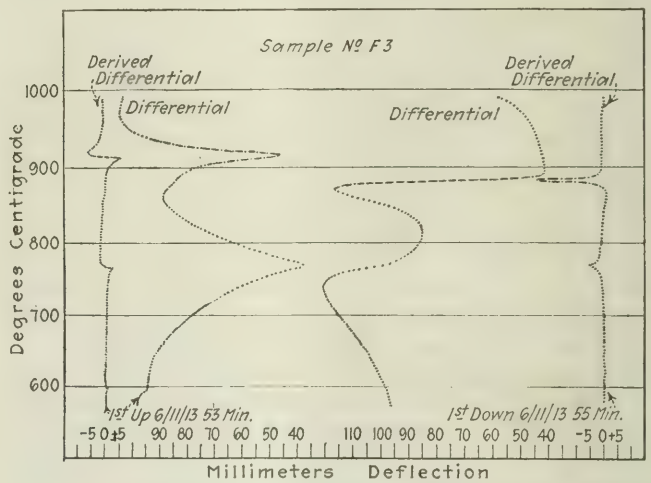

FIG. 11. COMPARISON OF DIFFERENTIAL AND DERIVED DIFFERENTIAL METHODS

Another method of interpreting the data is by means of the derived differential curve, first suggested by Rosenhain.[6] This amounts to differentiating the differential curve in respect to the tmperature and plotting the value so obtained against the temperature. The derived differential is accordingly related to the differential curve in the same manner that the inverse rate is related to the temperature-time curve. Thus if Θ is the temperature of the neutral body, the derived differential is the graph $\frac{d\,(\Theta - \Theta^1)}{d\Theta}$ vs. Θ. The method consists in observing successive values of $(\Theta - \Theta^1)$ for equal increments of Θ, say 2 deg. C., and plotting successive differences $(\Theta - \Theta^1)$ against Θ. The experimental arrangement is the same as that required for the differential method. Fig. 11 shows both differential and derived differential curves for the same sample of pure iron at the transformation points A_2 and A_3.

Present Status of American Glassware*

The American Pre-War Contribution to the Progress of the Glassware Industry Was Limited Mostly to Art Glass, Selenium-Red and Other Color Glass and Low-Expansion Glass; Now America Excels in the Manufacture of Glass and Glassware for All Practical, Industrial and Scientific Uses

By E. C. SULLIVAN

AMERICA had achieved certain results in glass chemistry before the war, but stimulus of necessity arising from the shutting off of foreign supplies both in glassmaking materials and of finished glasses has brought about more than ordinary progress during the past few years. As a result this country seems fully abreast of its competitors and in some respects has forged ahead, producing ware of better quality at no increase in price to the consumer and pushing development beyond that reached abroad.

America has long been the acknowledged leader in ornamental cut-glass, no other country having equaled the brilliance and richness of the American product.

An art glass which had its origin in America is the well-known Aurene or Favreuil glass, a glass of golden iridescence produced by spraying upon the surface of the finished article a liquid which reacts with the constituents of the glass and produces very remarkable soft color effects. It is made into vases, bowls for indirect lighting, etc.

Colored Glasses

A development of very great importance in the field of colored glass which owes its origin to America is the selenium ruby. Selenium, as is well known, is a rare element which is obtained chiefly as an impurity which separates from copper when that metal is refined electrolytically. It was discovered by a Pittsburgh glass maker that under certain conditions selenium could be made to produce a clear red of almost any depth desired. The selenium red has the great advantage for railway signal work that it transmits practically all the red rays and except for some yellow nothing else. In other words, it is a color filter. Other red glasses transmit other parts of the spectrum in addition to red. Gold ruby, for instance, transmits the red rays incompletely and at the same time lets some blue light pass. The selenium red is used universally by railways in this country for the danger signal, and tons of the comparatively rare element are consumed annually in preparing the glass.

In other railway signal glasses also this country is well in the lead, both in design of the semaphore lens and in production of the most efficient colors. Time was when each railroad had its own set of signal colors, the greens, for instance, ranging from blue-green to a yellow chrome-green, while the yellows varied from a reddish yellow to a green-yellow not far removed in hue from some of the yellow-greens. To straighten this confusion the glassmaking chemist called to his assistance the physicist and the physiological psychologist, and after years of collaboration the result today is for each color a universally adopted standard hue which affords maximum light transmission and maximum distinctiveness. The standard green gives more light than any other green and is less likely than any other green to be mistaken for another color, as yellow or blue. Similar standards now exist for each signal color. By the redesigning of the semaphore lens and the employment of the so-called high-transmission colors the intensity of the color-signal has been very greatly increased.

Low-Expansion Glasses

Another advance in glassmaking due to America was the introduction of low-expansion so-called heat-resisting glass for railway lantern globes. A trainman's lighted lantern set down on the car-platform or in the caboose is not unlikely to rest on a projecting brake-ratchet or on a broom handle, the result being that the flame plays directly against the glass. Then when the lantern is taken out into the rain or snow the overheated glass cracks and the signal fails—which in an emergency may be a matter of life or death. Chimneys of a thin glass of low expansion had been successfully used abroad. This glass, however, did not meet satisfactorily the severe conditions to which the thick-walled lantern-globe was subjected in service, and a glass was developed in this country for lantern-globes lower in expansion than any glass which had been made in commercial quantities up to that time. The low-expansion globes, both colorless and colored, are practically the only ones in use at present.

Glass for Electric Light Bulbs

Potash glass had always been considered essential for incandescent electric light bulbs, of which hundreds of millions are used annually. Glass chemists had developed non-potash glasses which appeared to have the same properties as the potash glasses, but the uncertainties involved in so radical a change were thought to outweigh the advantages, until the war, by excluding foreign potash, made action imperative. The non-potash glass has now been in use for some years and in many respects gives better results than the potash glass which it replaced. Except for certain special purposes a return to potash glass for bulbs in the future seems very doubtful.

This non-potash bulb-glass, however, like the potash glass and like all bulb-glasses from the beginning, contained 20 per cent or more of lead. One objection to the use of lead in glass is its cost. Even at its pre-war price of about 4c. per lb., it was an expensive glassmaking material, and during the war this price was doubled and trebled. Another drawback is the fact that among glassmakers there is a tradition that lead glass must be melted in pots and cannot be melted in a tank. Pot-melting is the old inefficient method of making glass, while tank-melting is the modern continuous op-

*Read at the Chemical Exposition, Chicago, Sept. 23, 1919.

eration adapted to the use of automatic conveying machinery for materials and to machine methods of working the glass. Two or three years ago a tank-melted bulb-glass was successfully introduced which contained neither potash nor lead, and its use has extended until a very large proportion of all lamp bulbs are now made of comparatively inexpensive materials by efficient labor-saving methods adapted to large-scale production.

Selective Spectrum-Absorbing Glass

In the field of glasses for transmitting or absorbing certain definite portions of the spectrum America appears to be at least abreast of her competitors.

There has been a demand for a glass which while absorbing as little of the visible spectrum as possible would afford the eye complete protection from the short wave-length ultraviolet. This has been accomplished in this country by development of a very pale but brilliant yellow glass which absorbs ultraviolet almost completely.

The glass just mentioned absorbs ultraviolet and transmits the visible light. Another recent American glass is unique in that it transmits ultraviolet and absorbs the visible. This ultraviolet has been called the invisible purple and is for the most part invisible. If all other light is excluded from the room, the radiation from an electric arc transmitted by this glass causes in the eye a puzzling and rather weird sensation of haze, owing to the fact that the eye cannot bring the rays to a focus as it can those of the visible spectrum. The weirdness is heightened by the ghastly appearance of teeth, eye-balls, finger-nails, etc., which like other fluorescent substances such as uranium glass, anthracene, rhodamite, willemite, change the invisible ultraviolet to visible light, which they radiate.

Welders' Glasses

For protection of operators of the electric-arc welding process from the radiation which if not guarded against causes serious burns of the skin and injury to the eyes, "welders' glasses" have been worked out which absorb not only ultraviolet but also infra-red and such excess of the visible light as causes glare. The light transmitted by these glasses is in the yellow green of the spectrum, in which visual acuity is highest.

Another unique glass absorbs only the infra-red. It is of pale-green color and transmits most of the visible, but in thickness of only 2 mm. absorbs 95 per cent or more of the invisible heat-rays. A piece of carbon paper so held in the rays from a projection lantern as to take fire almost at once is protected indefinitely if this glass is interposed. Ordinary glass is entirely ineffective. Eyeglasses of the heat-absorbing glass have a wonderfully comfortable and cooling effect in high-temperature work.

X-Ray Shield Glass

Various new glasses were developed to meet exigencies which arose during the war. One was a glass for X-ray shields which had about one-third the protective power of metallic lead of the same thickness and was the most effective glass used for the purpose up to that time. It formed part of a portable X-ray outfit used effectively close to the front lines in France. Colored glasses for marksmen, for naval gunners and for aviators, sextant glasses, special Fresnel ship lights, were other developments for direct use in connection with the war, and there were others which for military reasons are still held confidential.

Chemical and Cooking Utensils Glassware

The first high-grade chemical glassware made in this country was produced as long ago as 1902. It was fully equal to the best imported ware in resistance to chemical attack and was a low-expansion glass which could be heated directly over the flame without breaking. For 17 years, therefore, chemical glassware has been made in this country which for all practical purposes was on a par with the best foreign ware.

During the war other chemical glasses were put on the market, and today according to the findings of the Bureau of Standards at Washington better chemical glassware is made in this country than was ever imported.

With regard to resistance to chemical attack, the Bureau investigated flasks and beakers of five American brands with nine reagents each. Allowing one point for each of the 90 comparisons thus possible, the American brands score 60 points against 25 for the best foreign, 5 points being tied. Expressing the result in other words, this is equivalent to the American glasses having made a better showing in six of the nine reagents, an equal showing in one-half of one reagent, and a poorer showing in 2½ of the nine.

In power to withstand sudden cooling and in mechanical strength three American brands were found superior to the foreign, one of the American being far superior to all others in mechanical strength.

Apparatus built of the same glass used for flasks and beakers gave good service to chemical manufacturers during the war.

An expression from the Army medical authorities may be quoted as fairly typical of the enthusiasm of users of the American ware. They wrote that American flasks for preparing typhoid vaccine were far ahead of any such flasks ever obtained abroad; that the American glass had met the requirements so thoroughly that "aside from any sentimental reasons we would not take the foreign flasks if they were given to us."

In the same connection may be cited the fact that representatives of the American Chemical Society, the principal users of chemical glassware, appeared before the Ways and Means Committee of the lower house of Congress to urge that the domestic industry be fully protected by abolition of all duty-free importation of chemical glassware.

The glass baking-dish is a purely American development which seems to have established a permanent place for itself. The glass must possess the same qualities which are necessary for high-grade chemical glassware—resistance to the attack of water and dilute acids and alkalis, and low expansion-coefficient. A broad patent has been issued by the United States Patent Office on this invention. The unexpected feature of these dishes is the fact that baking takes place more rapidly in the glass than in metal, which has been shown to be due to the fact that glass reflects but a small per cent of the oven heat which is radiated upon it, while a metal utensil reflects 90 per cent or more of such heat.

Pots for Glass Melting

Before the war German clay had been considered essential to the manufacture of glass pots, but American clay pots are giving in every respect fully as satisfactory service as was had from the imported material.

A Rapid Method for the Analysis of Monel Metal

By Philip Covitz

BY COMBINING various well known rapid volumetric and gravimetric methods, an important saving of time without sacrificing accuracy is assured in analyzing monel metal, an approximate average percentage composition of which is:

Cu, 20 to 30; Ni, 60 to 70; Fe, 0 to 3.5; Al, 0 to 0.5; Mn, 0 to 3.5; C + Si, 0 to 0.8.

The usual procedure has been to dissolve a weighed quantity of the alloy (usually 1 gram) in nitric acid, filter off the silica and carbon, electrolyze the filtrate for copper, remove iron, aluminum and manganese by brominizing the ammoniacal electrolyzed solution, redissolve the precipitate and separate the elements; and finally determine nickel by the glyoxime method in the filtrate from the various precipitations. Carbon was obtained in a separate sample.

Separate Determinations

Inasmuch as all elements except carbon were determined on the same sample, precipitations and reprecipitations and washings resulted in the accumulation of large volumes of filtrates, which required considerable evaporation. The loss of time in concentrating filtrates should be avoided. In the method described below, this time factor is considerably reduced.

Carbon is determined by direct combustion in the Fleming apparatus.

Silicon is determined by filtering solution of metal before electrolysis, and ignition of the precipitate in a muffle.

Manganese is obtained by the bismuthate method on a separate sample.

Copper is found by usual electrolysis.

Nickel is determined directly on a separate sample, none of the elements interfering.

Iron and *aluminum* are separated from other elements in the solution of a separate sample, by precipitation with NH_4OH in presence of NH_4Cl. The precipitate is dissolved and the iron separated from the aluminum by boiling with KOH. The iron is then determined by the Zimmerman-Reinhardt process, while the aluminum is determined as $Al(OH)_3$ in the filtrate from the $Fe(OH)_3$.

Determination of Silicon

Weigh 1 g. of monel shavings into 200 cc. beaker, add 10 cc. HNO_3 (1.42), heat until dissolved and evaporate to approximately 7 cc. Dilute to 50 cc. with hot H_2O, filter through No. 42 Whatman 12.5 cm. paper into 300 cc. beaker. Wash thoroughly with hot H_2O, keeping volume of filtrate below 150 cc. Ignite and weigh SiO_2. If precipitate is heavy and discolored treat with HF and determine loss.

$$\text{Per cent Si} = 46.9 \times \text{SiO}_2 \text{ ppte.}$$

This method is open to criticism in that the silica is not dehydrated. In the opinion of the writer dehydration in most cases for silicon in monel metals is unnecessary. If the analyst should prefer it, however, the following procedure should be adopted:

Weigh 1 or 2 g. of borings in porcelain dish, add 10 cc. HNO_3 (conc.) and 5 cc. H_2SO_4 (conc.), evaporate cautiously to dryness, and heat until H_2SO_4 fumes freely. Cool, dissolve in 10 cc. conc. HCl, dilute to 50 cc. with hot H_2O, filter, wash with hot 1 to 1 HCl and hot H_2O, dry, ignite in muffle and weigh SiO_2. Do not use this filtrate for electrolysis.

Copper

Cool filtrate from SiO_2, make up to 150 cc., and add 5 cc. 1 to 1 H_2SO_4. Electrolyze, using a current of 1.5 amp. for 2 hours. Rinse electrodes, wash with C_2H_5OH, dry one minute in oven at 110 deg. C. and weigh deposited copper.

Iron and Aluminum

Weigh 1 g. of borings into 500 cc. beaker, add 10 cc. HNO_3, heat until dissolved, and dilute to 250 cc. with hot H_2O. Add 5 g. NH_4Cl, make ammoniacal, and boil 5 to 10 minutes. Allow precipitate to settle and filter through No. 40 Whatman paper (12.5 cm.). Wash thoroughly with hot H_2O. Reject filtrate. Transfer bulk of precipitate back to original beaker, pour hot 1 : 1 HCl through filter, and catch solution in this beaker. Wash paper free from iron. Warm beaker gently (do not boil). When precipitate has dissolved dilute to 250 cc. with hot H_2O, add 3 g. NH_4Cl and NH_4OH in excess. Boil 5 to 10 minutes, allow precipitate to settle and filter through No. 40 paper. Wash thoroughly with hot H_2O. Discard filtrate. Again dissolve precipitate as before, using as little HCl as possible, and wash filter thoroughly. Heat gently until iron is dissolved and add slight excess of 50 per cent KOH. Dilute to 150 cc. and boil 5 to 10 minutes. Let settle, filter through No. 40 and wash thoroughly with boiling H_2O. Save filtrate.

Iron

Place paper containing precipitate of $Fe(OH)_3$ into original beaker, add 10 to 15 cc. HCl and warm gently until precipitate dissolves. Add from dropper $SnCl_2$ solution drop by drop until decolorized, and then add 10 cc. $HgCl_2$ solution. Wash into 800 cc. beaker containing 400 cc. cold H_2O and 20 cc. preventive solution. Dilute to 600 cc. and titrate immediately with 0.03N $KMnO_4$ to end point which remains one minute. Conduct blank titration using same quantities of reagents.

To prepare 0.03N $KMnO_4$ dissolve 2 g. permanganate in H_2O and dilute to 2 liters; standardize vs. sodium oxalate. Preventive solution: dissolve 160 g. $MnSO_4$ in H_2O, dilute to 1750 cc.; add 330 cc. syrup H_3PO_4 (1.7) and then 320 cc. H_2SO_4 (1.84). Stannous chloride: dissolve 150 g. $SnCl_2$ in 250 cc. H_2O and 250 cc. strong HCl. Mercuric chloride: make up saturated solution with hot H_2O, allow to cool and filter.

Aluminum

To the filtrate from the $Fe(OH)_3$ add strong HCl in excess and boil thoroughly 10 to 15 minutes. Add excess NH_4OH and again boil 15 minutes. For small amounts of $Al(OH)_3$ it may be necessary to prolong the boiling and, in cases of traces of aluminum, standing over night in warm place is advisable. Filter off, wash precipitate thoroughly with hot H_2O, dry, ignite, and weigh as Al_2O_3.

$$\text{Per cent Al} = \text{wt. ppte.} \times 53.03$$

In some instances a trace of iron may dissolve on boiling the iron aluminum solution with KOH. This will of course show up with the Al_2O_3. In the event of any significant amount of Fe_2O_3 in the Al_2O_3 precip-

itate, purification may be obtained by fusing the combined oxides with KOH in a silver dish, dissolving the fusion in hot water and filtering off the Fe_2O_3. Aluminum may then be determined as indicated above.

Manganese

Weigh 1 g. borings into 300 cc. Erlenmeyer flask, add 20 cc. HNO_3, heat until dissolved and dilute to 60 cc. with hot H_2O. Add 1 g. sodium bismuthate and boil 5 minutes, or until permanganate color which forms is changed to brown. Now add 1 g. $FeSO_4$ and boil until brown fumes are expelled and the solution resumes its green color. Cool under tap to room temperature, add 1 g. bismuthate, agitate, and allow to stand 5 minutes. Filter by suction through asbestos and wash with 50 cc. 3 per cent HNO_3. Dilute filtrate to 300 cc. and titrate with ferrous ammonium sulphate solution to the disappearance of the permanganate color. A few trials will produce a satisfactory end point.

To prepare ferrous ammonium sulphate dissolve 30 g. $Fe(NH_4)_2(SO_4)_2.6H_2O$ in cold H_2O, make up to 2 liters and add 75 cc. concentrated H_2SO_4. Standardize against monel metal of known manganese content. In the absence of such, excellent results may be obtained by standardizing against a Bureau of Standards high-manganese steel (1 g. sample) to which has been added 0.25 g. pure copper, and, if available, 0.75 g. pure nickel. Three per cent nitric acid is made by diluting 60 cc. HNO_3 (1.42) to 2 liters.

Nickel

Weigh 0.1 g. borings into 200 cc. beaker, dissolve in 10 cc. HNO_3, dilute to 50 cc. with hot H_2O and filter into 500 cc. beaker. Wash thoroughly with hot H_2O and dilute to 300 cc. Add 10 cc. tartaric acid solution and make faintly alkaline with NH_4OH. Heat to 80 to 85 deg. C., add 50 cc. glyoxime solution, and allow to stand in warm place 15 minutes. Filter by suction through Gooch (which has been previously dried in oven at 110 deg. C. for 45 minutes, cooled and weighed) and wash thoroughly with hot H_2O. Dry at 110 deg. C. for 45 minutes, cool and weigh.

$$\text{Per cent Ni} = \frac{\text{wt. ppte.} \times 20.31}{\text{wt. sample}}$$

The following precautions should be observed: An excess of NH_4OH is harmful in that the red precipitate of nickel dimethyl glyoxime is slightly soluble in NH_4OH. The proper degree of alkalinity may be easily recognized by the appearance of the first permanent shade of the familiar copper ammonium blue. The solution should just barely smell of NH_4OH. The best temperature for precipitation is 85 deg. C.

In preparing the tartaric acid solution dissolve 150 g. crystalline tartaric acid in 300 cc. hot H_2O, filter and dilute to 500 cc.; in preparing the glyoxime, add to 4 g. dimethyl glyoxime in small flask 100 cc. ethyl alcohol. Connect flask to return condensor or to long piece of glass tubing, and warm on steam bath until the salt dissolves. Dilute to 500 cc. with C_2H_5OH, and filter.

Carbon

Run direct combustion on 1.3636 g. borings by any of the common combustion methods.

Gain in weight of absorption apparatus $\times$ 20 = per cent carbon.

The method advocated is one devised by William R. Fleming, metallurgist and chief chemist, Andrews Steel Co., Newport, Ky., with a few changes. (See *Iron Age*, Jan. 1, 1914.) The essential principle of this combustion is the rapid passage of oxygen through the combustion train (325 cc. per minute) and the short time of combustion (5 minutes). The absorption bulb is a double chambered apparatus (Sargent bulb), a large chamber containing 20, 40 and 60 mesh soda lime of 2 per cent moisture packed in alternate layers, and a small chamber containing P_2O_5.

The writer has found that it is safe to increase the time of combustion, and actually uses 15 minutes for combustion, especially on high carbon steels and cast irons. The furnace should be at 1000 deg. C. preferably, but should not fall below 950 deg.

Reports on Five Analyses

By running several determinations simultaneously, a monel metal may be analyzed with considerable accuracy in a few hours.

The following percentages were obtained by the above method.

Cu	25.88	28.92	28.70	28.34	27.59
Ni	68.41	67.05	66.65	66.12	67.25
Fe	3.09	1.75	2.26	2.58	2.48
Al	0.32	0.27	0.20	0.42	0.03
Mn	2.09	1.74	2.04	2.28	2.27
C	0.25	0.27	0.26	0.24	0.38
Si	0.02	0.02	0.02	0.04	0.02
	100.06	100.02	100.13	100.02	100.02

Cleaning and Pickling Iron and Steel for Enameling Purposes

A paper on this subject by Mr. R. R. Danielson of the Bureau of Mines was drawn up for presentation at the meeting of the American Ceramic Society, Sept. 24, 1919, but arrived too late for the meeting. It deals with the several phases of cleaning discussed under the following heads:

(*a*) Removal of grease.
(*b*) Removal of oxides.
(*c*) Neutralizing baths.
(*d*) Drying of wares.

Under the subject of grease removal, a list of the various types of chemical grease removers is given and the procedure for using them on a commercial basis is taken up. The advantages and disadvantages of scaling and cleaning are discussed. Considerable part of the paper is devoted to the problem of pickling with the various acids. Special attention is given to the use of niter cake as a substitute for acids and data are presented on the use of this material in commercial work.

Under the head of neutralizing baths, the development of mottling of gray ware enamels is discussed. The composition of a prepared neutralizing agent is given and the results are compared with those obtained with the use of soda ash on metal prepared for ground coating. The object of the paper is to present general data from cleaning and pickling practice as a guide for investigative work on the various problems of these processes. The paper in full will be printed in the *Proceedings* of the American Ceramic Society.

The Civil Service Commission announces that open competitive examinations for laboratory assistant (men only) will be held Feb. 4-5 and March 3-4, 1920.

Dangers in the Dyestuff Industry*

A Review of Incidental Accidents Due to Inexperience in New Industries, With Special Reference to the Dyestuff Industry—Explosion Risks of Dyes and Intermediates, of High Pressure Apparatus and of Inflammable Vapor Mixtures

By Dr. L. C. CONE,
National Aniline & Chemical Co., Buffalo, N. Y.

THE amount of danger in any industry is in inverse ratio to the knowledge and experience of the organization operating that industry. If a green crew, under the control of an inexperienced foreman, is employed in even so simple an operation as ice-cutting, there are bound to be accidents. The dyestuff industry of this country has been, in comparison with our older established industries, in the class of the above ice-cutting experiment. As a further complication added to inexperience has come the insistent demand for a large tonnage production of new products. These conditions have accentuated the dangers to such an extent that many serious accidents have resulted. Statistics gathered from our dyestuff and intermediates factories during the past five years would give a rather alarming picture of the risks of the business. There has been, however, on the part of the more stable companies engaged in the industry, no lack of appreciation of the nature of the risks involved. As a result of this appreciation of the dangers, constant progress is now being made in reducing the number and severity of accidents.

Inexperience a Source of Danger

Before we forget the hectic experience of the past five years some chemical genius, with a power of description and a keen sense of humor, should write the story of the war-time chemical development of this country. Many events in this development have the elements of sublimely ridiculous humor in them. One instance I have in mind where two college boys, without industrial experience, rented an old, abandoned, windowless brewery, with broken wooden floors, and a couple of rusty boilers. In this building they installed a makeshift aniline plant, and, in spite of every handicap, made aniline and sold it at a profit. It took American ingenuity and grit to make this plant go, and perhaps it also required American inexperience. An experienced aniline operator would have foreseen too many dangers to have ever started the project. Statistics of accidents from that and similar plants could hardly be considered the normal risk of our business. The proprietors themselves were always blue about the lips, and many a night they were just able to struggle home, get into a tub of warm water, drink a glass of milk, take a dose of salts, and go to bed. Is it not a wonder that, with the large number of such plants scattered all over the country, built by inexperience, and operated in spite of all hygienic laws, that the list of fatal accidents has not been greater? Gradually, however, we have been learning, partly by experience and partly by study, more about the risks of our business until today the hazards of the well-regulated dyestuff factory are little greater than the hazards of any mechanical plant containing a large and varied assortment of moving machinery. The chemical risks of the industry are largely centered about the manufacture of intermediates. The dangers of aniline, nitrobenzol, dinitrobenzol, dinitrotoluol, etc., have been so frequently discussed, and the methods used by companies like our own for minimizing the risks of these manufactures so thoroughly described, that there is no need to go into this matter at this time.[1]

Our company has never suffered a fatality from any of these poisons, although we have had some very sick men. Under the conscientious watchfulness of Dr. Kessler, of our Marcus Hook plant, the number of such cases has become relatively small. I am certain that if any safety man desires further detailed information in regard to our methods of handling these cases, Dr. Kessler in response to an inquiry would be more than willing to acquaint him with our experience.

Practical Results of Safety Work

The experience of our Buffalo works is the most illuminating experience of any of our plants, because in that factory is concentrated practically every risk of the dyestuff industry. While we do not make aniline there, we handle enormous quantities of the product under a very wide variety of conditions. We make and use large quantities of dinitrobenzol, dinitrochlorbenzol, and other poisonous products. In the first six months of 1918, as shown in the table, our serious chemical accidents were 21 in number against 59 of a mechanical nature, or 26.2 per cent. The first six months of 1919 there were 13 severe chemical accidents against 36 severe mechanical accidents, or 26.5 per cent. These figures, taken from a report by Mr. Doepke, our safety engineer, show that even under the rather strenuous conditions of high production prevailing during these periods, and during the very unsatisfactory labor conditions of 1918, the mechanical accidents far surpassed the chemical accidents. A closer analysis of the accident chart herewith will show that the majority of these accidents are of the preventable type. Acid burns, alkali burns, fume poisoning and eye accidents can, by education and constant watchfulness, be avoided, or at least reduced to a very low point.

Explosion Risks

Omitting further discussion in regard to these ordinary causes of chemical accidents, I wish to call attention to what I consider to be the greatest hazard of the dyestuff industry today, at least from the standpoint of severity of results. This is the explosion risk. From this cause alone we suffered three fatalities in 1918. These fatalities occurred in one instance where a considerable quantity of explosive dye ignited and killed three men. Records of the dyestuff industry,

*Read at the Eighth Annual Safety Congress of the National Safety Council, Cleveland, Ohio, October, 1919.

[1] *J. Ind. Eng. Chem.*, vol. 8, pp. 573, 1161; (1916).

during the last two or three years especially, have been full of reports of similar accidents at other plants. The disastrous fire at the plant of the Atlantic Dyestuff Co. in Nyack, N. Y., was caused by an explosion. According to the Sept. 1 issue of the *Journal of Industrial and Engineering Chemistry* (p. 893), there was recently another serious dyestuff explosion in Boston, Mass. Practically every dyestuff company in the country has had more or less experience along the same lines. This is a hazard which chemists and safety men must inform themselves about and which they must guard against more carefully. The greatest risks of explosions about dyestuff plants are three in number: Explosions of dyes and intermediates, explosions of pressure kettles, and explosions of vapors mixed with air.

Explosion of Dyes

The type of explosion which has caused our greatest loss is the explosion of dyes themselves. We have been prone to forget that dyes are organic compounds, some of them closely related to explosives. We have not accustomed ourselves to consider each new dye as a possible explosive, but have gone ahead, powdering and grinding our products in blissful ignorance until an accident has called our attention to the danger. A dye widely used for khaki shades on wool during the war was known as chrome yellow. This was made in very large quantities, dried, ground, packed, and shipped. It is doubtful if a single producer of this dye tested this material for its explosive properties before he began to produce it on a commercial scale, yet, as I can quickly demonstrate to you, by igniting a small portion of the dye, its quick burning properties render it more dangerous than many of our violent explosives. It is further doubtful if a single producer of this dye escaped the penalties of his failure to test the product. One large producer informed me that the total profits from his company's manufacture of this dye had been lost through disastrous fires and accidents. The same thing is true of another widely used chrome dye, which is frequently known as metachrome brown. This product has been the cause of at least three disastrous explosions in different companies to my own knowledge. With these experiences in mind we shall be very remiss in our duties if we do not examine every new dye for its explosive properties. A general rule, well known to chemists who have dealt with explosives, indicates what classes of dyes are apt to develop explosive characteristics. This rule may be summed up very roughly as follows: "Be extremely critical toward dyes which are to be handled in the form of dry powders unless they are well supplied with sulphonic acid groups."

Even after the dye is given a clean bill of health by the chemist because of its composition, it would not be remiss to have the dye tested before drying and powdering. This is a service which the dye producers owe to their consumers as well as to their employees, for many dyes are mixed in mills and exposed to conditions which might produce explosions.

Explosion of High Pressure Apparatus

With this danger of dye explosion eliminated, the next explosion risk which the chemical industry faces is that of pressure kettles. Chemistry at high pressure has only begun its development in this country. Processes which have normally been considered impossible are gradually being carried out under conditions of high pressure. The best illustration of this is the Haber synthesis of ammonia from nitrogen and hydrogen. This reaction will not take place between the two gases under atmospheric pressure, but when the two gases are brought together at very high pressure in the presence of a catalyst at elevated temperature, the two unite to a certain extent to form

ammonia. With the growth of our American chemical industry, reactions of this type will be more and more largely introduced into our manufacturing plants. As they are introduced, the explosion hazard will become greater and greater, and the safety men must co-operate closely with the technical engineers to see that every possible precaution is taken against disastrous results to our workmen and to our plants. It has been rumored that the very important intermediate, paranitraniline, has been made commercially by only one process in this country because another process, which offers many advantages, has a great explosion risk connected with it owing to very high pressure. If the American dyestuff industry is to be permanently successful, it must not permit itself to be restrained because of high pressure explosion risks. The control of this risk is primarily of course a technical engineering problem, but after the engineering lay-out is complete the safety man will find his opportunity to provide such appliances and such conditions as will give minimum destruction to life and property in case the engineering equipment ever fails.

Explosion of Inflammable Vapor Mixtures

The risks of explosion due to the ignition of mixtures and combustible vapors with air are already thoroughly appreciated by the technical and safety men. I only wish to call attention to the fundamental principles which must be followed in safety precautions to avoid explosions of this kind. While every effort to keep flames away from inflammable mixtures is commendable, these precautions alone will never entirely prevent ignition of explosive mixtures. Every effort must be concentrated on preventing the formation of such mixtures. Many disastrous explosions have occurred where every precaution has been taken to avoid the presence of all sources of fire. It is never possible to entirely do away with the chance formation of either frictional or electrical sparks. These are apt to be formed at most unexpected times, and at these times, if an explosive mixture of air and vapor is present, an unexplained disaster results. One of the most disastrous explosions I have ever witnessed, in which a large and well equipped plant was completely destroyed, was due to a chance frictional spark.

Static Discharges Must Be Guarded Against

As an illustration of the extreme difficulty of preventing ignition by chance sparks I will cite a case of my own observation where a large amount of toluene was stored in a glass enameled steel tank. It never occurred to the operators that a glass enameled steel tank is an ideal electrical condenser. The contents of the tank were not grounded in any way. A leak of toluene from the bottom valve soaked the floor under the tank; the workman, in attempting to repair this leak, made connection between the contents of the tank and the floor through a wire in his hand; the toluene on the floor immediately became ignited. Quick-witted workmen threw a few shovels of snow, which happened to be convenient, over the burning toluene and succeeded in smothering the flame before it ignited the tank.

For handling problems of this kind the safety engineer must have a very clear appreciation of the fundamental principles of both physics and chemistry, and must further work in close touch with the technical men of his own organization. By such close co-operation and careful study of each accident that occurs it will be gradually possible to eliminate the explosion risks of our industry.

Legal Notes

Exclusive License of a Patented Chemical Process Not a Sale of Business in a Foreign Country

By Wellington Gustin

THE distinction between the "sale" of a chemical company's foreign business and its contract to license the manufacture and sale of its products under the patents held by it in a foreign country was recently decided by the Supreme Court of Massachusetts (Arnold vs. North American Chemical Co., 122 N. E., 283). The inventor of a patented shoe "filler" brought suit against the defendant chemical company to recover his part of the proceeds of what he claimed was a sale of its foreign business.

Referring to the facts, it appears that the defendant chemical company, in a written contract with the plaintiff, agreed "that if it ever sells the filler business for Canada or for any foreign country," it would pay him a proportionate part thereof. The question for determination was whether the defendant had become liable under this clause of the contract.

The "filler business" was the right to manufacture and sell a certain trade-named shoe filler, a patented article used in the manufacture of shoes.

Terms of the Contract

After entering into the contract as stated above, the defendant chemical company made a contract whereby it granted to a British corporation, which theretofore had been its sole agent to sell this patented product in England, "an exclusive license under the patents in the territories of Great Britain and Germany to manufacture, use, exercise and sell this shoe filler from 1908 to August, 1919, subject to the further terms and conditions of the agreement, with right to assign the license or to grant sub-licenses therefor." Other terms and conditions followed as to the furnishing to the defendant by the British corporation of patterns of "outfits" and of the chemical compound required for the manufacture.

At the end of five years either party might terminate this part of the contract by one month's notice, whereupon the defendant was to furnish the British licensee with the formula by which to make the compound and further instructions as to its preparation, if necessary under some restrictions as to time. The payment to the defendant for these rights was a gross sum in several installments. In this connection it was stipulated that in the event the defendant should default for 21 days in furnishing the chemical compound required by the British licensee, the latter would have the option either to demand the formula with which the compound was made, with instructions as to its preparation, or to require a refund of all payments made to the defendant under the contract.

It was further provided that in case the British licensee should bring suit against any infringer of the patents before 1910 the defendant would bear half the court costs, lawyers' fees, etc. The defendant agreed to make no sales of the filler except for its American trade, and agreed also to pay one-half the British income tax in five annual payments.

In 1914 a supplemental agreement was entered into extending the term of the license for a further term of five years on six months' notice to the defendant.

This they called a "license extension." It was recited that the British corporation desired to discontinue its obligations as to Germany, and the defendant thereafter was to relieve it from paying German taxes and was to have the privilege of selling the product in Germany, Australia and South America. Defendant was to continue to supply the British corporation the compound for the manufacture of the filler on stipulated terms.

Was the Contract a Sale?

Since the plaintiff sued to recover under his contract with defendant, claiming a sale of the filler business for Canada and other foreign countries by the latter, the point decided by the court was whether these two contracts between the British licensee and defendant constituted a sale of its business in a foreign country.

There was no evidence introduced showing the patent laws of either England or Germany touching the sale or assignment of patent rights that might limit these contracts, therefore the court held that the words of the contracts and the acts of the parties were to be construed according to the common law principles prevailing in the State where the contract was made.

Definition of a Sale

The court defined a sale to be "the transfer of property from one person to another for a consideration of value." The word "sale," it said, had a well-defined meaning. It implies the passing from the seller to the buyer of the general and absolute title to property as distinguished from a special interest, a bailment, a license, a lease, a pawn, or other limited right falling short of complete ownership. Therefore it is plain that the contract between the defendant and the British corporation in form was not a sale. They called it an "exclusive license." Those terms imply a privilege or authority granted to another by one who possesses and retains a superior right or power. Applied to a patent it signifies the assignment by the patentee to another of rights less in degree than an interest in the patent itself. The law, however, will not be bound by the form of the transaction, but will look to the interest of the parties, considering all the words used, in order to determine whether there has been a sale.

Court Holds This Was a License, Not an Absolute Transfer

From this test the contract confers a license and is not the equivalent of a sale or absolute transfer. It was limited in point of time, for the period during which the British corporation had rights under the patents was definitely restricted, and well may have been less than for the term for which the patents were issued in England and Germany, as the unexpired term of these patent rights did not appear in the record.

Referring back to the terms and stipulations of the two contracts with the British corporation, they will be seen to impose restrictions and limitations and conditions such that the combined effect of these clauses demonstrates that the entire title to the patents in Great Britain was not transferred to the British corporation, and hence they did not amount to a sale. The obligation on the defendant to pay part of the expenses of litigation for infringement and to bear a part of the income tax, and the retention by the defendant of the formula of the compound show a retention of an interest, however small, in the British and other patents.

The other conditions which have been enumerated are confirmatory of an intention, as expressed in the contract, by the defendant not to sell and by the British company not to buy the "filler business." Without the aid of the defendant the plaintiff could not use the patent monopoly business in Great Britain.

Therefore, the court ruled, the effect of the written instruments was to grant a license and not to make a complete transfer, and judgment for defendant was affirmed.

Measure of Damages for Failure to Deliver Acid Under Contract

In an action founded upon a breach of contract a writ of attachment was quashed by the court for the reason that the damages for the breach were unliquidated. (T. J. Parker, Inc., vs. Anthony Hammond Chemical Works, 107 A., 44.) The plaintiff appealed from this order of the trial court to the Supreme Court of New Jersey.

From the plaintiff's case it appears that it entered into a contract with the defendant for the sale and delivery of 2,000 lb. of benzoic acid at $2 a lb., the delivery to be made in parcels of 500 lb. each and to begin in the first week of December, 1917, and to continue thereafter each week until the delivery was complete. The defendant failed to perform the contract, and plaintiff sought to recover the damages sustained by it by reason of this failure of performance and obtain its writ of attachment against the defendant.

Distinction Between Liquidated and Unliquidated Damages

The court said that on its face this was an action for unliquidated damages for which an attachment should not be granted. But plaintiff's claim to sustain its writ was that the damages are liquidated, in that after the breach of contract it went into the market and purchased 2,000 lb. of benzoic acid at $4.75 per lb., the daamges being definite and ascertainable by mere computation, the sum due being the difference between the contract price of $2 and the purchase price of $4.75.

However, the purchase by plaintiff was not made until more than a month after the time for the completion of the delivery under the contract had elapsed. Hence, the court said, this claim of plaintiff rested on an unsound basis. Ordinarily the difference between the contract price and the value of the goods at the date fixed for delivery is the measure of damages. In this case, whether the price paid was the fair market value of the acid at the time fixed for its delivery and whether the acid which was actually purchased was of the same character and value as that contracted for are questions to be determined by the jury and upon its determination the amount of the recovery would depend.

What the jury might determine is uncertain, and where the amount of the recovery depends on the finding of the jury upon these points the damages are, of course, unliquidated. Therefore the court held that a claim for damages for failure to deliver goods in pursuance of an executory contract of sale is a claim for unliquidated damages, and plaintiff's writ of attachment was quashed.

Copper-Aluminum-Iron Bronze as an Acid-Resisting Alloy

By O. L. Kowalke

ALTHOUGH much has been written concerning copper-aluminum-iron bronze for bearings, gears, etc., in machinery, there does not appear to be much data available on its acid-resisting properties. In tensile strength and ductility it ranks with mild steel; it can be easily machined to a nice finish; it can be forged while hot and also rolled into sheets. Sound castings of a wide range in size can be made of it free from shrinkage-holes or blow-holes.

A number of other alloys have been studied in the University of Wisconsin laboratories for their acid-resisting properties, but most of them were rather weak mechanically. The satisfactory mechanical properties of copper-aluminum-iron bronze prompted a study of the resistance to corrosion in acids and alkalis. Commercial bronzes were preferred over those made in the laboratory. Through the courtesy of the American Metal Products Co., Milwaukee, Wisconsin, several commercial bronzes were obtained for these tests, but the results on two only, Bronzes A and B, whose average compositions and properties are given below, will be reported here.

Composition:	Bronze A	Bronze B
Copper	87.0 per cent	85.6 per cent
Aluminum	9.8 per cent	10.81 per cent
Iron alloy	3.14 per cent	3.57 per cent
Ultimate unit stress	74,800 lb. sq.in.	66,600 lb. sq.in.
Per cent reduction in area	19.0 per cent	13.0 per cent
Per cent elongation in 2 inches	21.0 per cent	11.5 per cent
Specific gravity	7.71	7.58

The specimens for the corrosion tests were practically uniform in size, having dimensions approximately 1 in. long by 0.07 in. wide by 0.07 in. thick, were finished smooth, and had square edges. Each specimen was stamped to identify it for composition and serial number, and its total surface was measured so as to determine the corrosion per square inch.

Most of the corrosion tests were made at room temperatures, 72 deg. F. and 85 deg. F.; a few tests were made at 194 deg. F. The regular "C.P." acids of the laboratory were used and made up to strengths desired by titration methods. For the tests at room temperatures the various acids were put into covered beakers in amounts of 200 cc. Two specimens of bronze were set on edge in each beaker in such manner that all the surface was exposed to acid and that they did not touch each other. The specimens were removed periodically, washed in water, dried thoroughly, and then weighed on an analytical balance. The combined loss in weight of both specimens was then computed as loss per square inch. For the corrosion tests at higher temperatures wide-mouthed flasks were provided with rubber stoppers through which were inserted glass tubes 3 ft. long, open at both ends, to serve as condensers. An electrically heated oven kept the flasks and contents at an average temperature of 194 deg. F. In other respects the procedure was identical with that at room temperature. The results of the tests are given in Tables I and II for Bronzes A and B respectively.

It will be noted in Table I that Bronze A is resistant to several acids and particularly to sulphuric, lactic, phosphoric, tartaric, and acetic. Nitric acid attacks the metal readily, the concentrated acid acting violently. Hydrochloric acid and aqua ammonia both attack the metal too readily for commercial purposes. Caustic soda makes but little inroad on this metal either hot or cold; the slight gain during corrosion at 194 deg. F. is due to the formation of a film that was difficult to remove by rubbing with a cloth.

Table II gives the results for Bronze B, and the striking fact is the resistance to corrosion in sulphuric acid. By increasing the aluminum in this metal 1 per cent, the iron alloy about ½ per cent over the proportions in Bronze A, the resistance to corrosion is materially increased, even though the average temperature was 13 deg. F. higher. Nitric acid also attacks Bronze B too rapidly; hydrochloric acid attacks it more readily than Bronze A. Ammonia does not corrode this metal so readily as Bronze A.

TABLE I—BRONZE A

It is interesting to note from the results below that the corrosion in 35 per cent sulphuric acid of a forged specimen of Bronze A is only about one-half that of the rolled sheet and cast varieties.

Cost of Copper in 1918

IN submitting a report on the cost of producing copper for 1918, covering 85 companies, 95.5 per cent of the United States production, the Federal Trade Commission remarks that the reduction of prices by the Government did not hinder the maximum production nor prevent the very high earnings of copper companies. Table I shows the relation between production and prices, and despite the forced reduction in price by quarters in 1917 from 33.7c. to 32.4c., to 27.2c. and to 23.5c. per lb., production was practically stationary.

TABLE I. RELATION BETWEEN PRODUCTION AND PRICES

Year	Production,* Lb.	± %	Price in New York † Electrolytic, Cents
1913	1,224,484,098	.....	15.5
1914	1,150,137,192	—6.07	13.3
1915	1,388,009,527	+20.68	17.5
1916	1,927,850,548	+38.89	28.5
1917	1,886,120,721	—2.16	29.2
1918	1,908,533,595	+1.19	24.7

* U. S. Geological Survey.
† War Industries Board.

Again, on an aggregate investment of $672,000,000 it seems that about 30 cents investment is required to produce a pound of copper yearly. The profit per pound is shown by Table II to be 8.34c., or at an actual average rate of 28 per cent.

As a matter of fact 6 porphyries producing 570 million pounds netted 41.84 per cent; 6 lake companies producing 100 million pounds netted 46.97 per cent, and 6 other companies producing 424 million pounds netted 52.29 per cent. Another view of the matter is to be had from Table III, which shows that nearly half of the copper was produced for less than 16c, (and sold at 24.6c), while 85 per cent of the production cost less than 20c.

For the purposes of the Commission the term "cost per pound" is the cost of a pound of marketable copper at the Atlantic seaboard, including all items of labor, material, supplies, overhead, depletion and depreciation, but does not include interest, or income or excess profits taxes. Precious metals and by-products are credited. Production was reckoned by the quantity of copper in ore or concentrate, less smelted deductions, or by the smelter output.

Producing over 98,000,000 pounds	3	388,769,104	49.95	100.00	.13623
Total	11	778,360,356	100.00	.....	$0.14886

* Due to one company having a very low cost on account of the ore assaying close to three times as great as that of any other.

Costs were calculated on as near a uniform basis as possible, according to forms shown in blank in the report. The principal item of difference is in the calculation of the charge for depletion of the ore body. Two viewpoints stand out clearly in respect to the method of calculation and purposes of such a charge. For convenience they may be designated: (1) The cost viewpoint and (2) the tax viewpoint. The Commission has used the cost viewpoint in all reports, which makes an average difference of over 2c. per lb. and in individual cases as much as 5c. per lb. from that claimed by the companies.

The method of calculation used by the Commission is as follows: The actual cost of the mineral lands divided by the tons of ore in reserve plus the tons of ore mined gives the depletion cost per ton. To reduce it to depletion per pound, this result is divided by the recoverable pounds of copper in a ton of ore. The difficulties, of course, are to determine (1) the actual cost of the mineral land; and (2) the quantity of ore in the ground.

"Up to the year 1917," quoting the Commission, "few companies reported depletion as a cost; whereas practically all companies now include such a charge based on the revaluation of their mineral land. This is one of the largest single factors accounting for the apparently large increase in the cost of producing copper in the last year or two."

Table IV shows for the year 1918 the average costs of production by operations and by geographical divisions, giving the costs per lb. and the percentages of each item of cost, together with the same costs itemized by the elements of expense.

Items of note in Table IV are the relative low costs from Arizona and New Mexico, where most of the porphyries, as well as some high-grade mines, are located. Excessive values for depletion due to inflated land values may be noted in Montana, while the figure for mining reflects the fact that deep mines and high labor rates are the rule. Michigan mines from very deep levels, but the industry exists by reason of low smelting and refining costs as well as smaller transportation and other tolls. Abnormally low labor costs in Latin America are counterbalanced by the overhead.

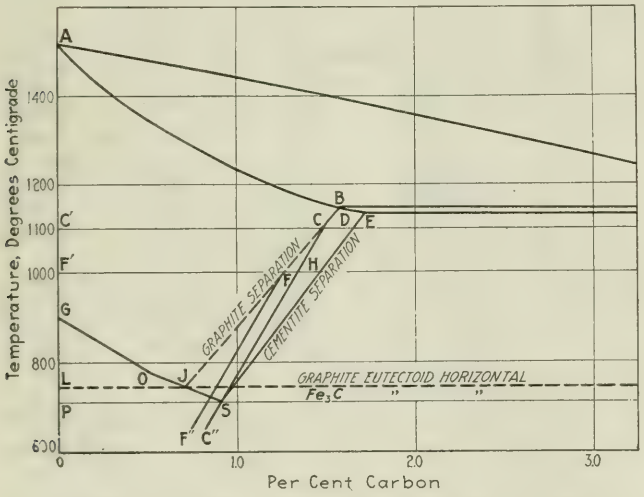
Reclassification according to nature of operations, as in Table V, also gives interesting materials for comparison.

Another interesting factor affecting the cost of production is the quantity of output. Table VI is a statement showing that large producers generally produced copper at a lower cost than the small ones.

Synopsis of Recent Chemical and Metallurgical Literature

Graphitization of White Cast Iron.—A study of certain phases of chilled-iron car wheel manufacture was made by Dr. MERICA and L. J. GUREVICH, of the Bureau of Standards, and the results, with certain theoretical conclusions, were presented in a brief paper read at the Chicago meeting of the American Institute of Mining and Metallurgical Engineers, Chicago, Sept. 24, 1919. The composition of the materials used ranged from C 3.67 to 3.90, Si 0.55 to 0.64, S 0.10 to 0.20, P 0.31 to 0.34 and Mn 0.53 to 0.63. Such variation in analysis did not affect the results, except that with higher carbons the temperature range at which graphitization is complete is somewhat more narrow. Speed of graphitization varies directly with the annealing temperature, but no considerable precipitation of carbon from these white irons occurred at 730 deg. C., even after 48 hours. This may therefore be taken as a safe annealing temperature for car wheels.

A curious fact was noted, that iron annealed at 1100 deg. C. and furnace cooled showed less graphite than another annealed for the same period at 1000 deg. C.



PORTION OF IRON-CARBON EQUILIBRIUM DIAGRAM

and cooled in the furnace, when practically all pre-eutectoid cementite had been decomposed. Quenching after annealing corroborated this observed difference. Upon slow cooling there is considerable crystallization of graphite upon the nuclei present, but a sample annealed at 1100 deg. C., cooled slowly to 1000 deg. C. and quickly cooled will have less graphite than one annealed at 1000 deg. C. and then quickly cooled. The authors present a diagram (shown herewith), to explain these facts. At 1100 deg. there is an amount of carbon in solid solution equal to C'C; at 1000 there is, if in equilibrium, a lesser amount equal to *F'F*. On cooling from 1100 deg. there is apparently a lag in its separation, not following line *BS*, but some line *CS*. Consequently upon arriving at the eutectoid horizontal, the combined carbon left in solid solution precipitates out as pearlite, and in amount will be greater in the sample cooled from 1100 than that from 1000. The graphite crystallizing about pre-existing nuclei along lines *CS* and *FF'''* is thus thought to come directly from solid solution. The fact that only 0.20 per cent of combined carbon was found in some specimens after annealing and slow cooling would either indicate that the graphite eutectoid lies at much lower carbon content than previously supposed, that a graphite eutectoid is precipitated on slow cooling, or that pearlite breaks up into graphite and iron directly upon its formation.

Recent Chemical and Metallurgical Patents

American Patents

Complete specifications of any of the United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Acetone From Acetic Acid.—Vapors of acetic acid are passed over a catalyst consisting of a manganese salt, metallic manganese or alloys of manganese, such as ferromanganese of high Mn content. The use of a metallic or alloy catalyst containing manganese presents the advantages, among others, that no extraneous support, such as pumice or the like, is required in order to present a large surface of catalyst to the vapors; and the relatively high heat conductivity of such catalyst renders it possible to maintain the temperature conditions practically constant, as well as uniform, throughout the reaction zone. At a temperature of 490 to 500 deg. C. yields of 95 to 98 per cent theoretical are obtained. (1,315,525; HARRY A. MORTON, assignor, to Union Carbide Co.; Sept. 9, 1919.)

Electrothermic Production of Acetylene From Hydrocarbons.—By introducing a high-frequency alternating current arc discharge beneath the surface of a hydrocarbon liquid, GEORGE O. CURME, JR., obtains a gaseous mixture containing hydrogen and acetylene. Using solar oil approximately 8.5 cu.ft. of gas was obtained per hour with a power input of 6.1 kw. for eight arcs in series. A frequency of 300,000 cycles or over is desirable. The gas analyzed: Hydrogen, 50 per cent; acetylene, 25 per cent; ethylene, 12.5 per cent; methane, 7 per cent; other hydrocarbons, 5 per cent. Approximately 4.5 lb. of carbon in the form of carbon-black distributed through the oil, and about 3.3 lb. of carbon in the form of electrode deposits, was produced per 1000 cu.ft. of crude gas. The oil consumption was about 50 lb. per 1000 cu.ft. of gas. (1,315,540; assigned, by mesne assignments, to Union Carbide Co.; Sept. 9, 1919.)

Acetaldehyde and Acetic Acid From Ethylene.—Ethylene combines with mercuric sulphate in aqueous solution to form a compound of the type $HgSO_4.C_2H_4$, which yields acetaldehyde and acetic acid by electrolytic oxidation. The cell consists of a steam-jacketed tank, mercury cathode, porous diaphragm and an anode of platinum, lead peroxide, magnetite or other suitable material. The anolyte is dilute sulphuric acid containing mercuric sulphate, the catholyte dilute sulphuric acid. The presence of cerium salts in the anode chamber acts catalytically in favoring the oxidation. Ethylene is passed into the anolyte through a perforated ring. If it is desired to produce acetaldehyde, the solution is heated above 21 deg. C., so that the acetaldehyde is volatilized as formed. If, however, acetic acid is the product required, the gas outlet is closed and the acetaldehyde is thus held in solution and further oxidized to acetic acid. (1,315,543 and

1,315,546; GEORGE O. CURME, JR., assignor, by mesne assignments, to Union Carbide Co.; Sept. 9, 1919.)

Production of Dimethyl Sulphate.—Anhydrous alcohol is saturated with SO_2 and treated with a mixture of SO_2 and Cl_2 in the proportions indicated by the equations:

$$Cl_2 + SO_2 + 2CH_3OH = CH_3Cl + CH_3HSO_4 + HCl.$$
$$Cl_2 + SO_2 + 2CH_3OH = (CH_3)_2SO_4 + 2HCl.$$

During the reaction, part of the methyl chloride is carried off by the excess SO_2 and the HCl formed. By heating the product on a water bath, the CH_3Cl, SO_2 and HCl remaining in solution are vaporized. The methyl chloride can be isolated from the gaseous products by passing through an alkaline absorption medium which will combine with the SO_2 and HCl. The product still contains methyl hydrogen sulphate, but by distilling under diminished pressure, this is converted into dimethyl sulphate and sulphuric acid, which may be easily fractionated.

$$2CH_3HSO_4 = (CH_3)_2SO_4 + H_2SO_4$$

Yields of well over 50 per cent by weight of dimethyl sulphate are obtained, which, in conjunction with methyl chloride also produced, represents a yield approaching the theoretical. (1,317,648; THOMAS H. DURRANS, assignor to A. Boake, Roberts & Co., Ltd., Stratford, London; Sept. 30, 1919.)

Apparatus for Treating Fuller's Earth.—The impurities contained in fuller's earth which has been used for filtering or bleaching hydrocarbon oils are soluble in sulphuric acid, so that the earth can be re-used after an acid treatment. The process consists in placing the earth in a vat and allowing sulphuric acid to percolate through the mass. The excessive time required in the method has led CLIFFORD M. HUSTED of Jersey City to devise an apparatus in which the complete purification (including washing and drying) may be accomplished in approximately one-half hour. The earth to be treated and the purifying chemical, sulphuric acid, are fed continuously into a rotating drum equipped with baffles to insure thorough mixing, and flanges to retard the passage of the mixture through the drum so that the earth is retained long enough to insure adequate treatment. The earth is now discharged into a washer and separating tank, where it is washed by a continuous stream of water. The bottom of the tank is inclined and provided with a screw conveyor which carries the settled earth to a second washer. From this the earth passes to a rotary drier. (1,317,372; assigned to Standard Oil Co.; Sept. 30, 1919.)

Graphitized Electrodes. — The manufacture of graphitized electrodes up to and including the 12-in. sizes which are the present commercial size limit involves the following essential steps: Petroleum coke, a low-ash, low-sulphur residue from petroleum distillation, is crushed and then calcined or "shrunk" by heating to approximately 1000 to 1100 deg. C., usually in a gas- or oil-fired kiln. Thereby the hydrocarbons which are volatile at or below the calcining temperature are largely expelled. The calcined material is again crushed, graded, bonded with pitch or similar heavy hydrocarbon, and molded or extruded through dies into the appropriate electrode sections. The resulting so-called green electrodes are then baked in gas-fired kilns, usually at a maximum temperature of about 1000 deg. C. They are then ready for graphitization, which is carried out in electric resistance furnaces at a much higher temperature range (above 2000 deg. C.). The principal advantages secured through graphitization are a large increase in electrical conductivity, and a marked decrease in the tendency to oxidation at the working temperature of the furnace. The present limit of industrial graphitization is reached at a diameter of approximately 12 in., either for round or square sections. As this limit is approached the proportion of losses through breakage or by the development of cracks or other defects undergoes a relatively very rapid increase, with the result that there exists a rather definite size limitation, above mentioned, beyond which graphitization has not up to the present time been commercially practiced. The breakage and the development of defects referred to occur partly during the baking of the electrodes prior to graphitization, and partly in the graphitizing operation itself.

In case graphitization is not desired, it is for many purposes advantageous to use in the electrode mix, instead of the low-ash petroleum coke, certain forms of carbon particles which are higher in ash but more compact, and of greater mechanical strength, notably hard coal of anthracite type. This coal is preliminarily calcined or shrunk to expel volatile matter, this operation being most advantageously carried out in electric calcining furnaces at relatively very high temperatures, up to 1600 to 1800 deg. C. This material is then crushed, graded, bonded and shaped, substantially as above described, and the green electrodes are then baked at about 1000 deg. C. to form the finished commercial article. Graphitization of these hard coal electrodes has not been commercially practiced. ARTHUR H. HINCKLEY of Niagara Falls has succeeded in making electrodes up to 24 in. in diameter from anthracite coal particles which can be graphitized. The process outlined above is modified as follows: The finely powdered anthracite coal (45 per cent to pass through a 200-mesh screen) is mixed with 12 to 15 per cent pitch in kneaders at 160 deg. C. The mass is briquetted in a steam-heated hydraulic press and baked at 1000 deg. C. The baked material is crushed and graded and is then ready for use. It is superior to the electrically calcined coal generally employed, since it has sufficient tensile strength to endure without fracture the strains set up in the electrode during the heating and cooling operations incident to baking and graphitizing, thus permitting the successful manufacture of larger electrodes. (1,317,497 and 1,317,498; assigned to National Carbon Co.; Sept. 30, 1919.)

Detinning Process.—Scrap tin is treated with a strong aqueous solution of caustic soda at 120 to 150 deg. F. in an iron tank which is lined with some material electro-negative to tin, such as graphite. The galvanic action set up between the graphite and the tin accelerates the solution of the tin. This operation is repeated until the bath is rich in tin. The tin solution is then transferred to a second iron tank. Bales of scrap tin are suspended in the bath and a current is passed, the tank being the cathode and the tin the anode. In this manner the tin from the bale is dissolved and deposited, while the tin is also deposited from the bath, so that the latter can be returned to the first tank. (1,316,926; CHARLES P. TATRO and GEORGE DELIUS of Seattle, assignors of one-third to BENJAMIN R. BRIERLY; Sept. 23, 1919.)

Cymene Sulphonic Acids.—Sulphuric acid of specific gravity 1.84 is caused to descend over baffle-plates, pebbles or coarse pumice stones, in a tower, which is heated and maintained at a temperature of 180 to 190 deg. C. Paracymene is heated to boiling and its vapors are passed up through the tower. The vapors come into contact with the descending hot sulphuric acid and are completely absorbed by it, with the formation of water and cymene disulphonic acids. The water escapes from the tower as steam and may be condensed in any suitable condenser attached at or near the top of the tower. The sulphonic acids, together with a slight excess of unused sulphuric acid, are carried downward by means of gravity, and discharged from the bottom of the tower. The product contains a considerable amount of cymene-2-sulphonic acid, which is separated from the disulphonic acid by well-known means, such as, for example, the formation of the barium salts by neutralizing with barium carbonate, filtering the solution of the salts of the sulphonic acids from the barium sulphate and concentrating the vapor to crystallization, when the barium salt of the monosulphonic acid of cymene separates first, leaving the barium salt of the disulphonic acid in solution, from which it may be obtained by the addition of alcohol. (1,316,823; JOSEPH A. AMBLER, HERBERT A. LUBS and HARRY D. GIBBS; filed under the act of March 3, 1883, 22 Stat. L., 625; Sept. 23, 1919.)

Book Reviews

INDUSTRIAL ELECTROMETALLURGY, INCLUDING ELECTROLYTIC AND ELECTROTHERMAL PROCESSES. By *Eric K. Rideal.* 259 pages. 25 illustrations. New York: D. Van Nostrand Co.

The history of the English chemical industry within the past fifty years is unique in many respects. Much of the pioneer work of the chemical key industries, such as the dye industry, was carried out in England. The industries were fostered and developed and soon became foremost in the world. Thereupon a period of relaxation set in, the industries became of secondary importance or they left the Empire entirely. Such was the case of the dye industry, which virtually passed out of existence in England and grew to enormous proportions in Germany; of the aluminum industry, which went to America; and of the tungsten industry, which became a German monopoly. These facts were pointed out by the British Association about fifteen years ago, when an earnest endeavor was made to revive the chemical and metallurgical industries at home; but it remained for the World War to make the English people fully realize the actual status of their industries. Soon after the outbreak of the war the chemist was called upon to produce chemicals and chemical products which had previously been imported from Germany and Austria. An urgent demand immediately arose for concise accounts of the best and most modern methods of making the chemical products in question. In response to this demand a number of the foremost British chemists and engineers arranged to publish series of practical handbooks. The book before us is the third in a series edited by Samuel Rideal. The remarkable rebirth and rapid development of the British chemical industries within the past three years is without doubt largely due to the untiring efforts of these chemists and engineers.

Dr. Rideal's book will be welcomed by American chemists and instructors, but in particular by the young electrochemist. The subject is admirably well treated and attractively printed and illustrated. The book is divided into the following eight chapters: Electrolysis in aqueous solutions; electrolysis in fused electrolytes; electrolytic preparation of the rarer metals; electrothermal processes; carborundum and oxysilicides of carbon; carbides; electrothermal nitrogen fixation by metals and metallic compounds; iron and the ferro-alloys. Not only are the various processes described from the technical point of view but considerable space is devoted to the underlying theories of the several chemical or thermal reactions. Those who wish to make a more thorough study of the subject will find the numerous literature references very convenient. There are very few misprints and but few misstatements. On page 92 the author states that there "has been no electrolytic process devised for the refining of tin," although America has been turning out electrolytic tin since 1916. The process was described in the *Engineering and Mining Journal* of that year. These minor defects will undoubtedly be removed in the second edition, which will surely appear, judging by the great popularity of this first edition.

COLIN G. FINK.

Personal

H. G. BAIN, until recently attached to the San Francisco office of the Midvale Steel & Ordnance Co. sales organization, has joined the Tacony Steel Co., Philadelphia, Pa., as sales representative for the upper part of New York State.

R. E. BAKER has resigned as works manager of the Keokuk Electro Metals Co. to accept a position as research engineer for the Victor Chemical Works at Chicago Heights, Ill.

ROY BRAKEMAN, formerly chief engineer of the Fairfield Works of the American Steel & Wire Co., Fairfield, Ala., is now associated with the Otis Steel Co., Cleveland, Ohio, as chief engineer.

S. E. BRETHERTON, JR., who recently returned from the Burma Mines Co., is now at Atascadero, Cal.

E. F. BRUNDAGE has severed his connection with the Maryland Chemical Co. and is now with the General Chemical Co., Baltimore, Md.

Dr. CHARLES F. CHANDLER of Columbia University is to be the recipient of the Perkin medal to be awarded at the meeting of the Society of Chemical Industry this month.

GEORGE C. DEWEY, recently in the U. S. Army, is now chemist and assayer with the Selby Smelting & Lead Co., at Selby, Cal.

Dr. F. GIOLITTI is in the United States on a mission from Stein & Co. of Paris, France, who have organized an American branch to exploit their ideas in gas furnace construction.

M. R. HULL has resigned his position as designing engineer and superintendent of power for the Nevada Consolidated Co. to accept a position as designing engineer for the affiliated companies the Chile Exploration Co. and the Braden Copper Co., with headquarters in New York City.

HENRY S. KENYON, formerly with the Thomas A. Edison Co., is head of the oil and wax division of the Southern Oil & Chemical Co., 21 Park Row, New York.

EDWARD D. KILBURN, who has been New York district manager of the Westinghouse Electric & Manufacturing Co., was recently elected vice-president and general manager of the Westinghouse Electric International Co.

F. G. MOSES, formerly at the Salt Lake City station of the Bureau of Mines, is now connected with The Barrett Co., in charge of the flotation oil department.

WILLIAM C. REDFIELD, Secretary of Commerce for seven years, has associated with H. P. Wilson in the investment security business under the name of Redfield & Wilson, 50 Broad St., New York City.

HUGH ROLLIN, formerly president of the Rollin Chemical Corp., is no longer president and general manager of the company, owing to a change in the stock control, and has severed all connection with the company.

DOUGLAS E. SCOTT, who for several years has been in charge of the experimental paper mill of Arthur D. Little,

Inc., Cambridge, Mass., has resigned and is now connected with the United Fruit Co., Boston, Mass.

HERVEY J. SKINNER, for many years vice-president of Arthur D. Little, Inc., Cambridge, Mass., has severed his connection with that organization and has opened an office as a consulting chemical engineer at 248 Boylston St., Boston, Mass. Mr. Skinner was with the Arthur D. Little, Inc., organization seventeen years, during which time it grew to its present large size, occupying a large modern laboratory building on the Charles River in Cambridge. Mr. Skinner has had a varied experience especially in pulp and paper problems and will specialize in development work on propositions requiring technical advice and assistance in putting them into commercial operation.

Current Market Reports

The Non-Ferrous Metal Market

New York, Jan. 5:—Copper holds steady at 19c. for near-by delivery, 19½c. for future delivery. There has been very little trading in tin, the February-March quotation being 58¾c. Lead and zinc are both firm.

	Cents per Lb.
Copper, electrolytic	19.00
Aluminum, 98 to 99 per cent	33.00
Antimony, wholesale lots	9.75
Nickel, ordinary	42.00
Nickel, electrolytic	45.00
Tin, Straits, spot	58.25
Lead, New York, spot	7.75
Lead, E. St. Louis, spot	7.50
Zinc, spot, New York	9.25
Zinc, spot, E. St. Louis	8.87½
Silver (Dollars per oz.)	1.35

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	28.50
Copper sheets, cold rolled (over 14 oz.)	30.50
Copper bottoms	37.00
Copper rods	29.50
High brass wire and sheets	25.50
High brass rods	24.50
Low brass wire and sheets	28.25
Low brass rods	28.25
Brazed brass tubing	37.25
Brazed bronze tubing	42.00
Seamless copper tubing	32.00
Seamless bronze tubing	36.00
Seamless brass tubing	30.50

SCRAP METALS

	Cents Per Lb.
Aluminum, cast scrap	23¼ @ 24¼
Aluminum, sheet scrap	22¼ @ 23½
Aluminum clippings	25½ @ 27
Copper, heavy machinery comp	14½ @ 14¾
Copper, heavy and wire	13⅝ @ 14
Copper, light and bottoms	12½ @ 12¾
Copper, heavy cut and crucible	15¾ @ 16
Brass, heavy	7½ @ 8¼
Brass, casting	10½ @ 10⅝
Brass, light	5⅝ @ 6¾
No. 1 clean brass turnings	8¼ @ 8⅝
No. 1 comp. turnings	11¼ @ 12
Tea lead	4.65 @ 4.75
Lead, heavy	6.00 @ 6.25
Zinc, scrap	4¼ @ 4½

RARER METALS

Cadmium	lb.	$1.50 @ 2.50
Cobalt	lb.	1.90
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00

The Iron and Steel Market

Pittsburgh, January 2, 1920.

Marketing problems in the iron and steel trade are relegated altogether to the rear, but there is much shopping on the part of jobbers and manufacturing consumers, who do not merely wish to match a certain piece of goods but rather are in search of material of all sorts for prompt delivery. They are quite bare of stocks, and shopping is likely to be more strenuous in the next few weeks than it was even in December. In contracting, on the other hand, there is little being done and little is to be expected in the next two months. Substantially all the tonnage the mills were willing to place under contract for the first quarter or half of the new year has been disposed of.

With the mills it is a question of production and distribution. The Steel Corporation and several of the independent producers have adhered to the March 21 or Industrial Board schedule of prices, and as higher prices would be paid by many buyers, and have been paid to some of the independent mills on comparatively large tonnages, it is necessary for producers who have sold at the basis prices to distribute their output very carefully so that regular customers may receive their appropriate quotas.

STEEL PRODUCTION PROSPECT BRIGHT

As to production, there is a reasonable prospect that within three or four months the mills will be able to approach measurably close to capacity output. In January, 1919, steel ingot production was about 87 per cent of capacity, output decreasing until approximately a 50-per-cent rate was reached at the middle of May, an increase at once beginning which brought the industry up to about an 83-per-cent rate in the fore part of September. The strike inaugurated Sept. 22 cut output by about one-half, and since then there has been a gradual recovery, production at the present time being at about 80 per cent. The strike is left behind, but labor shortage, labor inefficiency and lowered morale remain, the objective now being to correct the situation in these respects.

The present deficit in steel supply can of course be made up readily, provided production can be increased to the extent that should be expected and that consumptive demands do not very greatly increase. With capacity operation there would soon be room for the railroads to re-enter the market as buyers, and this is expected to occur. In all probability the large mills that have hitherto catered to railroad demand have been endeavoring to save some space for the railroad owners when control of their properties is returned to them March 1.

The acute deficit in steel supplies probably amounts to several hundred thousand tons, while the deficit represented by stocks in the hands of jobbers and manufacturing consumers being below normal may amount to more than a million tons. Capacity, however, in finished rolled steel is about 725,000 gross tons a week, while production is now at 550,000 to 600,000 tons a week, so that the case is far from hopeless. The longest time estimated for the trade to "catch up" and regain a normal basis is six months.

PRICE POLICIES AND PREMIUMS

Last March an agreement was reached between the "Industrial Board" set up by Secretary Redfield of the Department of Commerce and representatives of the iron and steel industry whereby certain price reductions would be made in the interest of stabilization of prices so that investors would be encouraged to proceed. Both parties to the agreement made statements that buyers should expect to buy, during 1919, at lower prices than those announced to become effective March 21. Within a short time the Industrial Board disappeared. In May and June various independent producers were cutting the March 21 prices, but the Steel Corporation and a few independents did not. Later, when the market was in position to advance, the Steel Corporation showed steadfast adherence to the regular schedule.

All that was positively known was that the Steel Corporation intended to adhere to the schedule during 1919, but a definite pronouncement has now been made showing that the Steel Corporation intends to continue the policy for an indefinite time, or until conditions radically change. Judge Gary, chairman of the Steel Corporation, in a statement given out after the directors' meeting of Dec. 30, indicated the corporation's adherence at this time to the policy, so that no change is to be expected even though 1919 has passed into history. With the Steel Corporation are several of the large independent producers and perhaps a few of the smaller producers. Higher prices than the March 21 schedule have been paid freely for early deliveries of the majority of finished steel products, but in the circumstances such prices must be regarded as "premium prices," the excess being due to the delivery time involved. Those who pay the premium prices are buyers who have no regular standing as customers of the mills adhering to the basis prices, or customers who desire tonnage in addition to that allotted them.

The Chemical and Allied Industrial Markets

New York, January 2, 1920.

The general chemical market remains firm, with better prices and smaller sales. The quotation on *oxalic crystals* jumped from 30@31c. per lb. to 31@32c. per lb. on car lots, and from 30@33c. per lb. to 32@35c. on less than car lots. *Calcium chloride*, fused lump, has been active, and as a consequence the low price has come up from $19 to $20 per ton, showing a present quotation of $20@$25 per ton on car lots and $30@$40 on smaller quantities. *Carbon tetrachloride* also jumped ½c., the present quotation reading 12½@14½c. per lb. *Potassium bichromate*, among the leaders in activity, is quoted at 32@33c. per lb. in car lots and 34@35c. per lb. in less than car lots, against 26@27c. and 30@33c. of the previous report. *Potassium permanganate* rose from 55@65c. to 70@75c. per lb., while *potassium prussiate red* went up to $1.10@$1.20 per lb. against $1.05@$1.15 of last week.

Alcohol at present is on a very unstable footing owing to the uncertainty as to the future of this item. *Ethyl* and *denatured alcohol* continue at the same nominal quotations of $5.25@$7 per gal. on the former and 80@82c. per gal. on the 188 proof and 76@78c. on 190 proof, denatured. *Methyl*, or *wood alcohol* is unobtainable, and the price has jumped to $1.57 per gal., against a high mark of $1.38 for last week. In order to restrict the sale of wood alcohol the Internal Revenue Department is bonding all handlers of this item.

Coal-tar products have exhibited nothing of especial interest, prices remaining firm. *Dimethylaniline* is still going up and is now quoted at 90c.@$1, against 60@93c. per lb. of the previous report, and there is very little on the market to be had even at this increased price. *Phenol* jumped from a previous high mark of 16c. to 19c. per lb., while *phthalic anhydride* is quoted at 70c.@$1 per lb.

Waxes have been inactive during the past week and prices remain unchanged. The *paraffine grades* are still behind in production, which partially accounts for the high prices at present. All contracts being written at present are for future delivery.

In *naval stores* the lower and medium grades are displaying an upward tendency in price, *rosin EI* rising to $19 for 280 lb., against $18.25 of last week. *Wood turpentine*, dest. dist., is now quoted at $1.51@$1.58 per gal.

In order to meet the demand of the buyers the prices of some of the vegetable oils have been dropped slightly, *olive oil* commercial coming down from $2.80 to $2.60 per gal., while *palm lagos* dropped a cent to 16c. per lb. *Rapeseed oil blown* came up 10c., with a range at present of $1.60 @$1.70 per gal., while *rapeseed oil refined* also went up 5c. to $1.65 per gal.

Another gap has been caused by the holiday and the absence of cables from the English and India rubber market leaves the domestic market somewhat unstable. Prices have gone up, with *up-river coarse* quoted at 36@37c. per lb., against 35c. last week, while *caucho ball* jumped from 51½c. to 54½c.

The *ferro-alloy* market remains practically unchanged, the only activity being in *spiegeleisen*, which jumped from $33@$45 to $40@$50 per gross ton. The low quotation on *ferromanganese* dropped to $100, making the present quotation $100@$130 per gross ton.

An active market in the ores and semi-finished products is predicted for the near future, the present prices, however, remaining.

Among the miscellaneous materials, *fuller's earth* is still scarce. Owing to uncertain labor conditions in Florida, the domestic grade of this item is practically unobtainable at $25@$30 per ton. *Barytes*, domestic white floated, which has been in heavy demand by the paint industry, is hard to find. The former quotation of $35@$40 per ton remains.

Chicago, December 31, 1919.

Firm prices in most lines mark the closing days of 1919 in the local market, excellent demand holding in all branches of the trade. A sharp decline has been experienced in pine tar products, but renewed demand is now tending to reestablish former high prices.

Heavy Chemicals: The formerly noted upward trend of *caustic soda* has been accentuated by heavy export shipments of granulated to Europe, $4.50 cwt. now being the ruling price, f.o.b. works. Domestic purchases of solid are also heavy and $4 f.o.b. works is quoted. *Bleach* also has taken a further advance to 2½c. and *soda ash*, light, ranges from $2 to $2.10 per cwt. Indications are that the market on the above-mentioned items is practically fixed for some time at the prices named.

Sodium bichromate has recovered from its violent spurt of three weeks ago when prices were named ranging from 30 to 40c. per lb. The price now is established, for the time, at least, at about 22c. Other items which have had interesting fluctuations recently are all holding firm, *potassium carbonate* being quoted at 27c., *acetone* at 15c. and *potassium prussiate, red*, $1.10, *yellow*, 70c.

Acids show no changes of interest except in *sulphuric*, the market having strengthened some, current quotation on 66 deg. being $22. *Muriatic*, 20 deg., at 2½c. and 40 deg. *nitric* at 8c. for spots show no change. Manufacturers report future production pretty well covered by contracts at prices only slightly less than those ruling for immediate delivery.

Coal-Tar Products: The effect of the coal strike was felt more keenly in this than in any other chemical line, as it curtailed production at a time when supply was already short on account of previous troubles in the steel industry. *Benzol* and *toluol* are hard to get in any great quantity, 32c. being the ruling price for available stocks. *Aniline oil* at 33c. and *aniline salts* at 36c. show no recent change. Supply on these two items is very short, and the prices quoted are for future delivery, spots demanding and receiving one or two cents more.

No great activity is noted in *benzoic acid*, 95c. being quoted on U. S. P. for today's delivery. *Salicylic acid* is under slightly better demand, 45c. still being asked. *Picric acid* is the weakest item of the line, plenty being offered at 20c. with no buyers visible at that figure.

Vegetable Oils: This line, owing to curtailment of users' activities during the coal strike, has been very quiet, but in the last few days a slight strengthening has been noted and indications are that some of the large consumers are preparing to enter the market for quantity contracts for future delivery. *Cotton oil*, crude, is today quoted ½c. higher at 19½c., and *prime summer yellow* advanced the same amount to 25½c. *Corn oil*, under the weak demand of the past few weeks, has done well to hold firm at 18c., sellers' tanks. *Linseed oil* some time ago advanced to $1.85 in tanks, $2.09 being asked for local deliveries in lots of 4 bbl. or less. With speculation rife as to the distribution of the forthcoming Argentine crop of seed, and with all crushers sold up to capacity for some time to come, it looks as if high prices in *linseed oil* will remain for some weeks at least.

With light demand, market in *cocoanut oil* and *soya bean oil* has been quiet, a slight firmness being felt in the last few days. At existing rates of exchange with the Orient, lower prices seem impossible. On *cocoanut oil* 18½c. in tanks, f.o.b. coast, is asked and 16½c. on *soya bean oil*.

Flotation Oils, Naval Stores: A sharp decline due to a weakening of demand, which in turn was due to the fuel shortage, occurred about ten days ago. From the previous high mark of $1.60@$1.65, .933 *pure distilled pine tar oil* has dropped to $1.35, and *destructively distilled* is quoted at the same figure. *Turpentine*, being shortest in supply, has fluctuated less, $1.85 now ruling against $1.95@$1.98 in the middle of December. *Rosin* shared slightly in the decline, quotation on F grade having dropped 50c. to $18.50.

Fertilizers: While the temporary shutdown of the great fertilizer plants here during the bituminous strike was not of sufficient length to seriously affect production for the year, it had the effect of skyrocketing prices on the local market. Ground blood is hard to get at the prevailing price of $7.75 and unground is quoted at about $7.50, a recent advance on the two lines of 40c. and 75c. respectively. Tankage is also up nearly 50c., quotation of high-grade ground being $7.25. All other grades are priced in proportion.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.		$0.60 – $0.65
Acetone	lb.	$0.20 –	.21 –

Sulphuric, 60 deg., tank cars	ton	12.00 – 16.00	–
Sulphuric, 60 deg., drums	ton	17.00 –	22.00 –
Sulphuric, 60 deg., carboys	ton	20.00 –	25.00 –
Sulphuric, 66 deg., tank cars	ton	17.00 – 18.00	22.00 – 23.00
Sulphuric, 66 deg., drums	ton	20.00 – 21.00	25.00 – 26.00
Sulphuric, 66 deg., carboys	ton	25.00 –	30.00 – 40.00
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	20.00 –	26.00 –
Sulphuric, fuming, 20 per cent (oleum) drums	ton	25.00 –	32.00 –
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	30.00 –	35.00 –
Tannic, U. S. P.	lb.	–	1.35 – 1.45
Tannic (tech.)	lb.	–	.42 – .55
Tartaric, crystals	lb.	–	.69 – .74
Tungstic, per lb. of WO	lb.	–	1.20 – 1.40
Alcohol, Ethyl	gal.	4.80 – 4.95	5.50 –
Alcohol, Methyl	gal.	1.50 –	1.52 – 1.57
Alcohol, denatured, 188 proof	gal.	–	.80 – .82
Alcohol, denatured, 190 proof	gal.	–	.76 – .78
Alum, ammonia lump	lb.	– .04½	.04½ – .04¾
Alum, potash lump	lb.	.08 – .08½	.09 – .09½
Alum, chrome lump	lb.	.15 – .16	.18 – .20
Aluminum sulphate, commercial	lb.	.01½ – .02	.02½ – .02½
Aluminum sulphate, iron free	lb.	.02½ – .03	.03½ – .03½
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.08½ –	.09½ – .10
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	–	.30 – .33
Ammonium carbonate, powder	lb.	.13 – .13½	.14 – .14½
Ammonium chloride, granular (white sal ammoniac)	lb.	.12½ – .14	.13½ – .15½
Ammonium chloride, granular (gray sal ammoniac)	lb.	.12 – .12½	.13 – .13½
Ammonium nitrate	lb.	.10 –	.11 – .12
Ammonium sulphate	lb.	.05 –	.06 –
Amylacetate	gal.	–	3.65 – 3.75
Arsenic, oxide, lumps (white arsenic)	lb.	–	.09 – .09½
Arsenic, sulphide, powdered (red arsenic)	lb.	–	–
Barium chloride	ton	90.00 – 95.00	95.00 – 100.00
Barium dioxide (peroxide)	lb.	.22 –	.24 –
Barium nitrate	lb.	.09½ – .10½	.11 – .12
Barium sulphate (precip.) (blanc fixe)	lb.	.03 – .03½	.03½ – .04
Bleaching powder (see calcium hypochlorite)		–	–
Blue vitriol (see copper sulphate)		–	–
Borax (see sodium borate)		–	–
Brimstone (see sulphur, roll)		–	–
Bromine	lb.	–	.65 – .75
Calcium acetate	cwt.	2.00 – 2.05	2.10 –
Calcium carbide	lb.	–	.04½ – .05
Calcium chloride, fused, lump	ton	20.00 – 25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02½
Calcium hypochlorite (bleaching powder)	cwt.	–	2.75 – 3.75
Calcium peroxide	lb.	–	1.50 – 1.70
Calcium phosphate, monobasic	lb.	–	.02 – .03
Calcium sulphate, precipitated	lb.	–	.09 – .09½
Carbon bisulphide	lb.	.05½ –	.06 –
Carbon tetrachloride, drums	lb.	.10½ – .11	.12 – .14
Carbonyl chloride (phosgene)	lb.	–	.75 –
Caustic potash (see potassium hydroxide)		–	–
Caustic soda (see sodium hydroxide)		–	–
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.08 –
Cobalt oxide	lb.	–	1.50 – 1.55
Copperas (see iron sulphate)		–	–
Copper carbonate, green precipitate	lb.	–	.28 – .31
Copper cyanide	lb.	–	.65 – .70
Copper sulphate, crystals	lb.	.08½ – .08¾	.09 – .09½
Cream of tartar (see potassium bitartrate)		–	–
Epsom salt (see magnesium sulphate)		–	–
Formaldehyde, 40 per cent	lb.	–	.20 – .37
Glauber's salt (see sodium sulphate)		–	–
Glycerine	lb.	–	.24½ – .26
Iodine, resublimed	lb.	–	4.50 –
Iron oxide, red	lb.	–	.03 – .20
Iron sulphate (copperas)	cwt.	1.00 –	1.20 – 1.50
Lead acetate, normal	lb.	–	.15 – .16
Lead arsenate (paste)	lb.	–	.13 – .17
Lead nitrate, crystals	lb.	–	.85 – .86½
Litharge	lb.	–	.09½ – .10½
Lithium carbonate	lb.	–	.50 –
Magnesium carbonate, technical	lb.	–	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	2.00 – 2.63	2.75 – 3.00
Magnesium sulphate, commercial	100 lb.	1.75 –	2.00 – 2.50
Nickel salt, double	lb.	.14 –	.15 –
Nickel salt, single	lb.	.12 –	.15 – .16
Phosgene (see carbonyl chloride)		–	–
Phosphorus, red	lb.	–	.75 – .90
Phosphorus, yellow	lb.	–	.35 – .37
Potassium bichromate	lb.	.32 – .33	.34 – .35
Potassium bitartrate (cream of Tartar)	lb.	–	.58 – .60
Potassium bromide, granular	lb.	–	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.25 –	.30 –
Potassium chlorate, crystals	lb.	.18 – .20	.21 –
Potassium cyanide, 98-99 per cent	lb.	nominal	
Potassium hydroxide (caustic potash)	lb.	.28 – .32	.35 – .40
Potassium iodide	lb.	–	3.55 – 3.60
Potassium nitrate	lb.	.19 –	.21 –
Potassium permanganate	lb.	–	.70 – .75
Potassium prussiate, red	lb.	–	1.10 – 1.20
Potassium prussiate, yellow	lb.	–	$0.40 – $0.70
Potassium sulphate	ton	$225.00 –	–
Rochelle salts (see sodium potas. tartrate)		–	–
Sal ammoniac (see ammonium chloride)		–	–
Sal soda (see sodium carbonate)		–	–
Salt cake (sodium sulphate)	ton	15.00 – 21.00	–
Silver cyanide	oz.	–	1.25 –
Silver nitrate	oz.	–	.81½ – .82½
Soda ash, light	100 lb.	1.95 –	2.05 –
Soda ash, dense	100 lb.	2.25 – 2.35	2.50 – 2.75
Sodium acetate	lb.	.05½ – .06½	.07 – .08
Sodium bicarbonate	100 lb.	2.35 –	2.75 – 3.00
Sodium bichromate	lb.	–	.22 – .25
Sodium bisulphate (nitre cake)	ton	3.00 – 8.00	10.00 –
Sodium bisulphite	cwt.	1.80 – 1.90	2.00 – 2.10
Sodium borate (borax)	lb.	– .09	.09 – .10
Sodium carbonate (sal soda)	100 lb.	1.35 – 1.50	1.50 – 1.75
Sodium chlorate	lb.	.15 –	.16 – .18½
Sodium cyanide, 96-98 per cent	lb.	.30 –	.31 – .34
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	–	4.10 – 4.35
Sodium molybdate	lb.	2.50 –	3.25 –
Sodium nitrate	100 lb.	– 3.25	3.75 – 4.00
Sodium nitrite	lb.	.15 – .17	– .18
Sodium peroxide, powdered	lb.	–	.30 – .32
Sodium phosphate, dibasic	lb.	.03½ – .04	.04½ – .05
Sodium potassium tartrate (Rochelle salt)	lb.	–	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .24	.24 – .26
Sodium silicate, solution (40 deg.)	lb.	.01½ – .02	.02 – .02½
Sodium silicate, solution (60 deg.)	lb.	.02½ – .03	.03½ – .04½
Sodium sulphate, crystals (Glauber's salts)	cwt.	1.15 – 1.25	1.50 – 2.00
Sodium sulphide, crystal, 60-62 per cent. (conc.)	lb.	–	.05 – .06
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05½ –	.06 –
Sulphur, crude	ton	22.00 –	–
Sulphur dioxide, liquid, cylinders	lb.	–	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.10 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	2.95 –	3.15 – 3.40
Tin bichloride (stannous)	lb.	.44 –	.46 – .50
Tin oxide	lb.	–	.60 –
Zinc carbonate, precipitate	lb.	–	.20 –
Zinc chloride, gran.	lb.	.12½ –	.13½ – .14
Zinc cyanide	lb.	.49 –	.50 –
Zinc dust	lb.	.09 – .11	.11 – .14
Zinc oxide, dry American	lb.	–	.09½ – .12
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.50
Alpha naphthylamine	lb.	.32 —	.50
Aniline oil, drums extra	lb.	.34 —	.36
Aniline salts	lb.	.43 —	.45
Anthracine, 80% in drums (100 lb.)	lb.	.90 —	1.00
Benzaldehyde (f.f.c.)	lb.	1.00 —	1.15
Benzidine, base	lb.	1.10 —	–
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.31
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech.	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.52
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech.	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U.S.P., in drums (100 lb.)	lb.	.18 —	–
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.80 —	.85
Cresylic acid, 95-97%, dark, in drums	gal.	.85 —	.90
Cresylic acid, 50%, first quality, drums	gal.	.60 —	–
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	2.25
Dimethylaniline	lb.	.90 —	1.00
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.65
Diphenylamine	lb.	.58 —	.75
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.06½ —	.07½
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.40 —	.45
Nitro-toluol	lb.	.27 —	.30
Ortho-amidophenol	lb.	3.00 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.90 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.15 —	.18
Paranitraniline	lb.	.95 —	1.10
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.50 —	4.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.70 —	1.00
Phenol, U.S.P., drums (dest.), (240 lb.)	lb.	.12½ —	.19
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.00
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.45 —	.60
Salicylic acid, U.S.P.	lb.	.45 —	.50
Salol	lb.	.90 —	.95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 —	.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30

*Nominal quotations.

Toluidine	lb.	$1.70 —	$2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.32 —	.30
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.44
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white pure	lb.	.63 —	.66
Carnauba, No. 1	lb.	.80 —	.83
Carnauba, No. 2, regular	lb.	.65 —	.78
Carnauba, No. 3, North Country	lb.	.44 —	.50
Japan	lb.	.18½ —	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.06 —	.07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.06½
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.09
Paraffine waxes, refined, 128-130 m.p.	lb.	.09¾ —	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.12
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.13
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$1.25
Pine oil, pure, dest. dist.	gal.	1.00
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	47
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.65
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.00
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	....
Pinewood creosote, ref.	gal.	.51

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$17.00 —	$17.50
Rosin E-I	280 lb.	17.55 —	19.00
Rosin K-N	280 lb.	19.75 —	23.00
Rosin W. G.-W. W.	280 lb.	22.50 —	24.25
Wood rosin, bbl.	280 lb.	17.00 —	17.50
Spirits of turpentine	gal.	1.65 —	1.69
Wood turpentine, steam dist.	gal.	1.63 —	1.64
Wood turpentine, dest. dist.	gal.	1.51 —	1.58
Pine tar pitch, bbl.	200 lb.	8.25 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	14.90
Retort tar, bbl.	280 lb.	15.00 —	15.25
Rosin oil, first run	gal.	.86 —	.91
Rosin oil, second run	gal.	.88 —	.93
Rosin oil, third run	gal.	.95 —	1.12
Rosin oil, fourth run	gal.	1.05 —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.50 —	$0.51
Upriver coarse	lb.	.36 —	.37
Upriver caucho ball	lb.	.36½ —	.37
Plantation—First latex crepe	lb.	.54½ —	....
Ribbed smoked sheets	lb.	.54¾ —	....
Brown crepe, thin, clean	lb.	.46½ —	.48¾
Amber crepe No. 1	lb.	.53 —	....

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.	lb.	$0.18½ —	$0.20
Castor oil, AA, in bbls.	lb.	.21¼ —	.22
China wood oil, in bbls.	lb.	.22½ —	.24
Cocoanut oil, Ceylon grade, in bbls.	lb.	.17½ —	.19
Cocoanut oil, Cochin grade, in bbls.	lb.	.19½ —	.22
Corn oil, crude, in bbls.	lb.	.19 —	.21½
Cottonseed oil, crude (f.o.b. mill)	lb.	.18 —	.19
Cottonseed oil, summer yellow	lb.	.22 —	.27
Cottonseed oil, winter yellow	lb.	.23 —	.28
Linseed oil, raw, car lots	gal.	.... —	1.87
Linseed oil, raw, tank cars	gal.	1.80 —	1.84
Linseed oil, boiled, car lots	gal.	.... —	1.90
Olive oil, commercial	gal.	2.50 —	2.60
Palm, Lagos	lb.	.16 —	.17½
Palm, bright red	lb.	.16½ —	.17½
Palm, Niger	lb.	.16 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23¼ —	.23½
Peanut oil, refined, in bbls.	lb.	.26 —	.28
Rapeseed oil, refined in bbls.	gal.	1.45 —	1.65
Rapeseed oil, blown, in bbls.	gal.	1.60 —	1.70
Soya bean oil (Manchurian), in bbls., N. Y.	lb.	.17¾ —	.22
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.15¼ —	.15⅞

FISH

Winter pressed Menhaden	gal.	$1.20 —	....
Yellow bleached Menhaden	gal.	1.23 —	....
White bleached Menhaden	gal.	1.25 —	....
Blown Menhaden	gal.	1.26 —	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.03½ —	.04½
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	.16 —	.18
Chalk, English, light	lb.	.05 —	.07
Chalk, English, light	lb.	.04½ —	.06
Chalk, English, dense	lb.	$ .04 —	$ .05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	13.50 —	18.00
Fluor spar, acid grade, lump, f.o.b. mines	net ton	30.00 —	35.00
Fluor spar, acid grade, ground, f.o.b. mines	net ton	35.00 —	45.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, TN	lb.	1.10 —	1.15
Shellac, D. C.	lb.	.... —	....
Shellac, V. S. O.	lb.	.... —	....
Shellac, Diamond I.	lb.	.... —	....
Shellac, orange, fine	lb.	1.25 —	....
Shellac, orange, superfine	lb.	1.20 —	1.30
Shellac, A. C. garnet	lb.	1.10 —	....
Shellac, bleached, bone dry	lb.	1.35 —	....
Shellac, bleached, fresh ground	lb.	1.10 —	1.15
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	80-90 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	35-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	30-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-90 at Chester, Penn.
Silica brick	1,000	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.20 —	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.21 —	.50
Ferro-manganese, 70-80% Mn.	gross ton	100.00 —	130.00
Spiegeleisen, 16-20% Mn.	gross ton	40.00 —	50.00
Ferro-molybdenum, per lb. of Mo.	lb.	3.00 —	3.50
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1.25 —	1.40
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	5.50 —	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	7.50
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	6.50
Petroleum coke, refinery, Atlantic seaboard	net ton	12.00 —	12.50
Fluor spar, gravel, f.o.b. mines	net ton	..... —	25.00
Manganese ore, 45% Mn and over	unit	.50 —	.75
Manganese ore, chemical (MnO_2)	gross ton	60.00 —	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	9.00 —	15.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	7.50 —	10.00
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

*Government prices.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.80
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	16.00
Yellow pine, 3x4 to 8x8, 20 ft. and under	M.	48.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago	M.	50.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis	M.	40.00
Roofings, tar felt (14 lb. per 100 sq. ft.)	ton	70.00
Roofings, tar pitch (in 400-lb. bbl.) carlots	ton	21.00
Roofings, asphalt pitch carlots	ton	34.00
Roofings, asphalt felt carlots	ton	63.00
Roofings, slate-surfaced, per roll of 108 sq. ft. carlots		2.25
Roofings, slate-finished shingles, 100 sq. ft. carlots		6.00
Linseed oil, raw in barrels	gal.	1.75
Linseed oil, 5 gal. cans	gal.	1.90
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14¾
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.15½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13¾
White lead, dry and in oil, 5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

BRIDGEPORT—I. Pick, c/o A. E. Fisher, archt. and engr., 373 Fulton St., Brooklyn, N. Y., is having plans prepared for the construction of a 1-story silverware factory. Estimated cost, $30,000.

HARTFORD — The Hartford Rubber Works, Park and Bartholomew Aves., has awarded the contract for the construction of 3 additions to its plant to Stone & Webster, 147 Milk St., Boston. Estimated cost, $2,225,000.

STRATFORD (Bridgeport P. O.)—The Albert-Peck Co., Bruce Ave., will build a 2-story, 67x180-ft. silverware factory. Estimated cost, $50,000. Work will be done by day labor.

District of Columbia

WASHINGTON—The Dist. Comrs., Room 320, District Bldg., will soon award the contract for the furnishing of 1 oxy-acetylene welding equipment and supplies for the McKinley Manual Training School.

Illinois

QUINCY—Lockwood, Green & Co., engrs., 38 South Dearborn St., Chicago, will soon receive bids for the construction of a 3-story, 60x175-ft. drug factory, for the Monroe Drug Co., 601-11 North 4th St. Estimated cost, $200,000.

ROCKFORD—The Rockford Paper Box Board Co., Catherine St., has awarded the contract for the construction of a 3-story, 100x100-ft. paper boxboard factory, to the Holm Page Co., 1604 4th Ave. Estimated cost, $85,000.

Louisiana

NEW ORLEANS—The Marland Oil & Refining Co., Ponca City, Okla., plans to construct a large refinery here with the necessary pipe lines to the north Louisiana oil fields; also build and equip a large line of tank steamers. Estimated cost, $7,000,000. E. W. Marland, Ponca City, president.

Maryland

CURTIS BAY (Baltimore P. O.)—The Armour Fertilizer Co., 1501 Munsey Bldg., Baltimore, has awarded the contract for the construction of a fertilizer plant on the waterfront, to Westinghouse, Church, Kerr & Co., Inc., 37 Wall St., New York City. Estimated cost, $2,000,000.

HAVRE DE GRACE—E. M. Smith plans to build a brick plant and is in the market for machinery for same.

Massachusetts

MEDFORD—The trustees of Tufts College plan to construct a chemical laboratory building on the Campus.

PITTSFIELD—The General Electric Co. will soon receive bids for the construction of a 1-story, 80x400-ft. enameling plant. C. C. Chesney, manager.

Michigan

HIGHLAND PARK (Detroit P. O.)—The Maxwell Motor Co., Oakland Ave., has awarded the contract for the superstructure for the proposed 1-story, 315x557-ft. pressed steel plant, to the U. S. Structural Co., 520 Book Bldg., Detroit. Estimated cost, $450,000.

MUSKEGON HEIGHTS (Muskegon P. O.)—The Shaw Electric Crane Wks., McKinney St., Muskegon, plans to construct a 1- and 2-story foundry and machine shop at McKinney and Park Aves. Estimated cost, $2,000,000. Manning, Maxwell & Moore, McKinney St., Muskegon, engrs.

Minnesota

ST. PAUL—The Western Chemical Co., Hutchinson, is having plans prepared for the construction of a 3-story, 90x120-ft. chemical factory on Malcolm Ave., here. Estimated cost, $125,000. Downs & Eads, 803 Phoenix Bldg., architects.

Missouri

JOPLIN—A stock company is being organized to build a zinc oxide factory. Estimated cost, $300,000. Address J. Leopold, secretary of the Chamber of Commerce.

Montana

MISSOULA—The Missoula Hide & Wool Co., 511 West Main St., is having plans prepared for the construction of a 2-story, 40x200-ft. tannery. Estimated cost, $25,000. Charles H. Stehling Co., 401 4th St., Milwaukee, Wis., architect and engineer.

Ohio

CLEVELAND—The Crucible Steel Forge Co. will soon award the contract for the construction of a 1-story, 60x900-ft. rolling mill, heat-treating plant, machine shops and warehouse, on Grant Ave. Estimated cost, $300,000. D. W. Wells, 6600 Grant Ave., mgr. James H. Herron, West 3rd St., and St. Clair Ave., architect and engineer.

CLEVELAND — The Enamel Products Co., Eddy Rd. and Taft Ave., has awarded the contract for the construction of a 1-story, 60x190-ft. factory, to the Crowell-Lundoff-Little Co., 571 Euclid Ave. Estimated cost, $75,000.

MACEDONIA—The Pyrite Brick Co. has purchased a site and plans to build a 1-story brick plant on same. Estimated cost, $250,000. Peter Schneider, care of Bldrs. Exch., Rose Bldg., Cleveland, manager.

Oklahoma

GRANDFIELD—The Uncle Sam Oil Co., 1409 Minnesota Ave., Kansas City, Kan., plans to construct a 1-story refinery at the George Hancock Farm. Estimated cost, $500,000.

PRYOR CREEK—V. V. LONG & CO., consult. engr., 1300 Colcord Bldg., Oklahoma City, is preparing preliminary plans for the construction of a water purification plant, etc., for the city.

New Jersey

HOBOKEN—The White Metal Mfg. Co., 1006 Clinton Ave., is having plans prepared for the construction of a 6-story, 135x135-ft. factory and a 2-story, 20x80-ft. foundry. J. C. Schaffer & Co., 38 West 32nd St., New York City, architect and engineer.

New York

BINGHAMTON—The W. R. Hollingshead Co., manufacturing chemists, 148 Oak St., has purchased a site and plans to construct a 4-story factory on same. Estimated cost, $150,000.

BROOKLYN—The Federal Composition Paint Co., 17 Battery Pl., New York City, has awarded the contract for altering a 3-story factory at 258 41st St., to the William Kennedy Constr. Co., 215 Montague St. Estimated cost, $60,000.

North Carolina

LEXINGTON—The city will receive bids until Jan. 20 for the construction of a filter house and installation of filter tubs, coagulating basin, etc. Estimated cost, $500,000. G. C. White, Durham, engineer.

North Dakota

WEBSTER—The Bd. of Educ. will receive bids until Jan. 20 for the construction of a 2-story, 94x140-ft. school. Laboratories will be installed in same. Estimated cost, $145,000. Oscar Magnus, clk. Edwins & Edwins, Northwestern Bldg., Minneapolis, Minn., architects.

Texas

FT. WORTH—The Invincible Oil Corp., 208 West 8th St., plans to build a 5000-bbl. refinery addition in the northern part of the city. Estimated cost, $500,000. W. R. Spann, 208 West 8th St., archt. and engr.

Wisconsin

SHEBOYGAN—C. W. Boley, city engr., and the Bd. of Pub. Wks., City Hall, will receive bids until Jan. 19 for purchasing and installing sterilizing equipment for purifying the water in Lake Michigan used for the city water. Estimated cost, $11,000. J. Steimle, clerk.

TOMAH—The Tomah Rubber Works, 176 16th St., Milwaukee, has awarded the contract for the construction of a 2-story, 100x100-ft. factory, to Charles Larson, Tomah. Estimated cost, $45,000.

Wyoming

CHEYENNE—The Bd. of Trustees of the Memorial Hospital of Laramie Co. will receive bids until Jan. 27 for the construction of a 4-story, 200x200-ft. hospital at 23rd and House Sts., for Laramie Co. An X-ray apparatus and laboratory equipment will be installed in same. Estimated cost, $300,000.

Ontario

MERRILTON—The Canadian Steel & Forging Co. is having plans prepared for furnishing equipment for the proposed steel plant addition. Plans include the installation of enameling and pickling equipment. Estimated cost, $200,000. J. J. Wernette, 441 Houseman Bldg., Grand Rapids, engineer.

NEWMARKET — The city is having plans prepared for the construction of sewers in Darcy and Yonge Sts.; also a sewage disposal plant and an activated sludge plant. Estimated cost, $60,000. E. A. James Co., Ltd., 36 Toronto St., Toronto, engineer.

TORONTO—Balwins Limited, Ashbridges Bay, has awarded the contract for the construction of a 1-story, 70x800-ft. steel plate mill at Ashbridges Bay, to Canadian Allis-Chalmers, Ltd., 212 King St., W. Estimated cost, $200,000.

TORONTO—The Oakoal Co., King St., E., has offered the city $15,000 for its garbage, proposing to erect a plant and make same into fuel briquets. City spends $175,000 yearly at present on garbage disposal.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23-26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9, and 10.

THE AMERICAN ELECTROCHEMICAL SOCIETY, New York Section, will hold a meeting, Jan. 23, on "Cheap Cyanide and Its Disposition."

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16-19.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE MINING AND METALLURGICAL SOCIETY OF AMERICA will hold a meeting in New York Jan. 13.

Industrial Notes

THE ANHEUSER-BUSCH BREWING CO. is converting a part of its plant into a factory for the production of bodies for automobile trucks and stake wagons. It will be known as the Busch Body Plant.

THE FEDERAL RUBBER CO. of Cudahy, Wis., has opened a sales branch at 1016 Market Street.

ROGERS, MAYER & BALL announce the extension of their facilities for the examination and appraisal of oil properties through the addition to their staff of Mr. Carl N. Anderson, formerly engaged with the Illinois Geological Survey and the Gulf Oil Corporation.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., has added to its sales engineering staff Albert A. Casey, of Cincinnati, Ohio.

THE LAKEWOOD ENGINEERING CO., of Cleveland, Ohio, announces that as an inducement to industrial plant managers, engineers and others to study their interdepartment transportation problems and more fully realize how industrial tractors and trucks help to conserve labor and in-

crease production, an offer of three awards, $1,000, $500 and $250, is made for the three best analyses of the application of the Lakewood Tier-Lift Truck. This contest is open to all except employees of the Lakewood Engineering Co. All papers must be in by Jan. 30, 1920, and the awards will be made prior to Feb. 28, 1920. The award committee has been appointed by the Society of Industrial Engineers.

THE RICHARDSON-PHENIX CO., Milwaukee, Wis., announces that its Philadelphia office, which was closed on account of the lubricating engineers in that office going into Government service during the war, is now reopened, and is in a position to give prompt service in all matters pertaining to the scientific lubrication of machinery. George F. Fenno is the manager.

WESTINGHOUSE, CHURCH, KERR & CO., INC., announces the appointment of Russell W. Stovel as consulting engineer, to devote his time to the company's electrical and mechanical works.

THE LINCOLN ELECTRIC CO. announces that Paul M. Lincoln, for many years commercial engineer of the Westinghouse Co., has resigned from that organization, to enter the consulting engineering field, and in that capacity will have active charge of motor application engineering for the Lincoln Electric Co., Cleveland, Ohio.

LOUIS A. DUFFY, recently of the J. Frank Dunbar Co., New York City, and Stephen H. Sears, formerly connected with the Firestone Tire Co., Akron, Ohio, have opened an office at 133 Front St., New York City, as brokers in crude rubber, under the firm name of Duffy & Sears.

THE UNIVERSITY OF ILLINOIS, Urbana, Ill., announces that owing to the meetings of the National Brick Manufacturers' Association and the American Ceramic Society, which have been scheduled for the last two weeks in February, the dates for the short course to be given by the department of ceramic engineering have been fixed for March 1 to March 13, 1920. Programs of the course are now available for distribution.

THE UNITED ELECTRIC CONSTRUCTION CO., INC., announces the opening of its Cleveland (Ohio) office at 558-559 Hippodrome Annex.

THE ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., announces that the Vancouver Engineering Works, Ltd., Vancouver, B. C., has given an order for a "Greaves-Etchells" furnace.

DR. FREDERIC DANNERTH, consulting chemist and specialist in the industries of rubber and related gums, announces the removal of his offices to the Board of Trade Bldg., 800 Broad St., Newark, N. J.

THE GENERAL FIRE EXTINGUISHER Co., Providence, R. I., was taken over Jan. 1 by a new company—Grinnell Co., Inc. The related industries which the Grinnell Co. takes over consist of fire protection, power and process piping, steam, hot water and gas heating, drying, sales of pipe, fittings, valves and supplies.

WALTER A. ZELNICKER SUPPLY CO., St. Louis, announces that Hugh L. Siegal has been appointed assistant to the president. He was formerly general sales manager for the Ford Roofing Products Co.

THE ELECTRICAL REFRACTORIES Co. is the successor to the Novelty Clay Forming Co., having offices at East Palestine, Ohio.

IVAN P. TASHOF, specialist in inventions relating to the chemical, electrochemical and metallurgical industries, announces the opening of an office in the Victor Bldg., 724 Ninth St., N. W., Washington, D. C., for the practice of patent and trade-mark law.

THE YOCUM LABORATORIES is the new name of the business conducted for many years by John H. Yocum at 325 Academy St., Newark, N. J., which began business Jan. 1, 1920. On May 1 the corporation will take possession of its new laboratory at 168 Colt St., Irvington, N. J., which is now being erected under the most recent ideas as to laboratory construction.

THE CREDITORS' COMMITTEE of the British-American Chemical Company, Inc., 42 Broadway, New York City, announce, under date of Dec. 12, 1919, to the creditors, parties to the plan of reorganization and composition agreement, as follows: "The undersigned readjustment committee, acting under the plan for the reorganization of the British-American Chemical Co., Inc., dated Jan. 6, 1919, beg leave to advise you that they became the purchasers of the property and assets of the company named under judicial sale and caused the same to be conveyed to the British-American Chemical Corp. of New Jersey as thereby authorized. The said corporation has been more conservatively capitalized than the plan referred to contemplated. No mortgage bonds have been issued. The preferred stock is limited to $250,000, instead of $400,000, is entitled to 8 per cent dividends instead of 7 per cent, and after July 1, 1920, is convertible into common stock, dollar for dollar, at the option of the holder. The distribution of 10 per cent cash and 50 per cent preferred stock will be made to the creditors parties to the reorganization plan on approval by the court of the final report of the receiver, concerning which you will shortly receive due notice.

"I. M. Dittenhoefer, W. M. Wadden,
"Committee."

THE AUTOMOTIVE PRODUCTS CORP. of New York, which specializes in the exportation of automotive products, announces that it has secured exclusive sales right for all foreign territories of the products of the Standard Roller Bearing Co. of Philadelphia, covering its roller and ball-bearings. It also announces having completed arrangements to export the products of the New Jersey Car Spring & Rubber Co. of Jersey City. Special attention will be given to the metric sizes, which are in great demand abroad at this time in practically all automobile markets, to replace equipment which has deteriorated or been destroyed during the last five years of war when none could be secured, and of new parts and equipment on thousands of machines now being exported from this country or produced in other markets and for which such equipment is not locally available.

THE BOOTH ELECTRIC FURNACE CO., whose incorporation was announced in these columns recently, has opened up the following district offices with a complete staff of engineers and metallurgists, in connection with the sale of electric furnaces for melting steel, iron, and non-ferrous metals: For New York and New England, Edward B. Stott & Co., Flatiron Bldg., New York City, with E. F. Tweedy, secretary of the company, directly in charge; for eastern Pennsylvania, New Jersey, Maryland, Delaware and southern Atlantic coast states, Northern Engineering Co., 308 Chestnut St., Philadelphia, with F. W. Doran in charge; for northeastern Ohio, western Pennsylvania and western New York, Charles L. Foster, formerly sales manager of the Electric Furnace Co., of Alliance, Ohio; with offices at 879 Arcade, Cleveland, Ohio.

THE MID-CONTINENT OIL, GAS & REFINING Co., with offices in Chicago, Kansas City and Oklahoma City, announces that the Cherry process for producing gasoline by electrochemical means will be used in a 2000-lb. refinery to be constructed at Vernon, Woodson Co., Kan.

THE UNITED STATES STEEL CORP. has been given a contract from the Government of Holland for between 15,000 and 18,000 tons of steel rail for the Dutch railways in East Indies.

THE YORK HARDWARE & BRASS Co. has closed a contract with the American Metallurgical Corp., Franklin Trust Bldg., Philadelphia, for the installation of a 1000-lb. revolving electric furnace of the Weeks type for the melting of brass and copper alloys.

Belgian industries still require raw materials and tools, which are coming in slowly owing to the unfavorable exchange and the difficulty of obtaining credit. Materials for the lining of pits in coal mines are needed, as well as cables, beams and machinery of all sorts; also high resistant galvanized steel wire for cable manufacture. The coke ovens require sulphuric acid and heavy tar oils. Resins, iron ore, billets and pig iron, and machine tools of every description are needed. The glass industry needs sulphate of soda. About 45,000 tons of wood pulp are required, as well as many kinds of chemicals, particularly aniline colors. China clay is in demand.

THE ELECTRIC FURNACE Co., Alliance, Ohio, has just installed nine new Baily Electric Furnaces for melting a wide range of non-ferrous metals and alloys, as follows: The Drew Electric & Mfg. Co., Cleveland, Ohio, has purchased a 105-kw. furnace for melting yellow brass. The Nolte Brass Co., of Springfield, Ohio, has installed a 105-kw. furnace, of 1500-lb. capacity for melting yellow brass. The Kennedy Valve Co., Elmira, N. Y., has installed a 105-kw. electric furnace for red brass. The American Bronze Corp., New York City, has contracted for two 1500-lb. electric furnaces for melting bronze. The Dominion Steel Products Co., Brantford, Ont., Canada, has installed a 50-kw. furnace of 500-lb. capacity for yellow brass. The Deming Co., Salem, Ohio, will melt yellow and red brass in a furnace of 500-lb. capacity. The Miller Pasteurizing Machine Co., Canton, Ohio, will use its Baily Electric 50-kw. furnace for yellow brass. Landers, Frary & Clark, of New Britain, Conn., will melt aluminum in a 50-kw. furnace that has a capacity of 200-lb. of aluminum per hour.

ARTHUR D. LITTLE, INC., chemist and engineer, Cambridge, Mass., through its information department, is planning a series of bibliographic studies, to be circulated among the public, university and special libraries of the United States, and the firms and individuals interested in the various studies. Those in course of preparation are: Chemical Warfare; Alcohol from Waste Sulphite Liquors; Industrial Research; The Automobile and Tractor at the Front; The Electric Furnace; Industrial Laboratories; Molasses; The Chemical Action of Light; Woods and Fibers Used as Paper-Making Materials. Copies of the first three are ready and may be had upon request.

Manufacturers' Catalogs

THE BLACKMER ROTARY PUMP CO., Petoskey, Mich., has issued the eleventh edition of the "Blackmer Rotary Pump," which is illustrated and described.

THE STAR BRASS WORKS, Chicago, Ill., has recently issued a 12-page bulletin, No. 6, pertaining to its line of small steam and water jet apparatus, comprising steam and water syphons or ejectors, also small steam jet pumps applicable to apparatus requiring vacuum, used as centrifugal pump primers, etc., fully illustrated, also including considerable engineering data involved. Copies will be sent upon request.

THE MONEL METAL PRODUCTS CORP., Bayonne, N. J., announces new booklets, ready for distribution, descriptive of Monel metal and its properties.

THE WHEELER CONDENSER & ENGINEERING Co., Carteret, N. J., calls attention to a new bulletin, No. 112-B, entitled "Condensers, Pumps, Cooling Towers, etc." This bulletin illustrates the latest developments in condenser practice. It shows a surface condenser containing 50,000 sq.ft. of surface. Sixteen condensers of approximately this size are now under construction. These will contain approximately 1,000 miles of Crescent Brand tubing drawn in the large Wheeler tube mill. The bulletin shows photographs of a number of actual installations of surface condensers. It illustrates and describes surface condensers, jet condensers, barometric condensers, the Wheeler-Edwards air pump, the Wheeler rotative dry vacuum pump, the Wheeler turbo-air pump, the patented Wheeler steam jet air pump, Wheeler centrifugal pumps for all services, jet condensers, barometric condensers, natural and forced draft cooling towers, feed water heaters, and Wheeler evaporators and driers.

THE J. G. WHITE ENGINEERING CORP., New York City, has published an attractive booklet entitled "Nitrate Number One," which briefly illustrates and describes the design and construction of the nitrate plant No. 1.

THE LEEDS & NORTHRUP Co., Philadelphia, Pa., is distributing Catalog No. 86B on the Optical Pyrometer. This bulletin illustrates and describes the use of the optical pyrometer with the hardening forging furnaces, instructions for using, the general use and theory of temperature measurement.

THE GLENS FALLS MACHINE WORKS, Glens Falls, N. Y., has issued two leaflets on rotary sulphur burners. One gives in a table the various sizes, sulphur burned per hour, approximate weight and floor space, together with a description of a 36 in. by 8 ft. machine. The other leaflet gives a table of sizes and combinations, with rated capacities.

THE STRONG-KENNARD & NUTT Co., Cleveland, Ohio, has issued a functional chart showing results gained by proper safety supervision.

THE AEROIL BURNER CO., INC., Union Hill, N. J., calls attention to a new bulletin describing and illustrating thawing outfits and torches for thawing out frozen cars, pockets, hoppers, pipes, switches, loading gates, chutes, etc.

WALLACE & TIERNAN CO., INC., New York City, has issued a leaflet entitled "Adjustable Orifice for Chemical Solutions."

THE SCIENTIFIC UTILITIES CO., INC., New York City, has published a catalog in which chemical glassware, thermometers and laboratory supplies are listed, which should be useful for the chemist and purchasing agent.

Volume 22 — New York, January 14, 1920 — *Number* 2

Annual Meeting of The Mining Engineers

THE annual meeting of the American Institute of Mining and Metallurgical Engineers will be held in New York City, February 16 to 19, inclusive. Owing to the congested condition of hotels in New York City it is necessary at this early date to urge all who expect to attend the meeting to secure hotel accommodations well in advance. The local committees in charge of this meeting are making strenuous efforts to provide for the convenience and entertainment of members who come from a distance. In spite of all that these committees can do, however, it will be necessary for visiting members to take all possible precautions to insure finding hotel accommodations when they arrive.

Mr. Hoover and The Presidency

REPEATED mention of HERBERT HOOVER in connection with the Presidency will be received with gratification by his engineering friends and associates, even though the publicity may be distasteful to a man of Mr. HOOVER'S nature. For several years we have joined with others in raising our voice in support of more active participation by engineers in Government affairs. Repeatedly we have said that the Government would be more efficient if we had fewer lawyers and more engineers in legislative and executive positions, and we see no reason for not extending that observation to include the highest executive position in the Government. The decision of the Democratic National Committee to hold the party convention in San Francisco gives an added impetus to Mr. HOOVER'S candidacy, he being a Californian by adoption. Probably Mr. HOOVER'S greatest claims to political recognition are his undoubted business ability, thorough grounding in economics and familiarity with European conditions. Other possible candidates are more prominent politically, but none of them approach Mr. HOOVER in positive qualifications.

What Kind of an Engineer Are You?

FOUR kinds of technical engineers are to be reported by the census enumerators who are now taking the fourteenth decennial national inventory. Limitation to four varieties is due to an undersupply of cogs in the great census-counting machine now operating at Washington. Civil, mechanical, electrical and mining engineers are to be the proud possessors of these four cogs. All other practitioners of engineering will be forced to trace back their relationship and claim the one of these four titles that appears to be most becoming to them.

Looking at the matter from the basis of alphabetical initials of engineering titles, there seems to be one too many cogs supplied. For only three combinations of C, M and E are required to designate those chosen, as well as the left out, chemical, metallurgical, marine, military, efficiency, as well as that large cosmopolitan class called etcetera engineers. However, not wishing to detract from the seriousness of the subject, it may be asserted that engineers as a whole are not inclined to be overly particular about their titles. The reason for this is that, as they become more proficient, they widen their scope to cover an increased amount of engineering activities in other fields.

It is probable that the great majority of the readers of this journal will choose to be counted with the mechanical engineers. Any one of the other three of the four chosen could do the same without stretching their qualifications very far. The civil engineer deals mainly with the static mechanics of bridges, highways, railroads and pipe lines. The electrical engineer has mastered the mechanics of electrical phenomena. The mining engineer has been schooled so that he is able to direct the activities of machines and miners in the bringing forth of mineral and ore. No outsider should register among these specialized groups unless he is very closely associated with one of them and more than slightly familiar with its work.

As the census years go by, it is to be hoped that other cogs will spring forth and that the chemical and metallurgical engineers will be separated from this broad classification, which from its very nature is capable of subdivision without end and must always provide for the etcetera engineers.

The Steel Strike Officially Called Off

THE steel strike is officially ended and Mr. FOSTER of unsavory reputation has resigned as secretary-treasurer of the committee which deliberately plotted the disruption of the steel industry through a strike for power. Friends of the American Federation of Labor have felt that its reputation for sane leadership and constructive action was greatly damaged by the activities of men of the Foster type. There can be no doubt that the country was never sympathetic with the steel strike, because it was plainly a contest for power and had no justification. Its leaders were avowed radicals, if so mild a term can be applied, and Labor is well rid of them if their retirement from leadership should prove permanent. The strike was a failure from the beginning and resulted only in economic loss to the steel companies and their employees. Steel production in 1919 was reduced by 2,500,000 tons, due to the strike, and laborers lost untold sums in wages. In other words, the strike was a net loss to the country which the public eventually will have to pay.

State of the Milling Art in 1919

IN THE milling of copper ores as well as in the smelting end, there have been few changes of importance made in existing plants, nor have new plants of large size been built. With high labor and commodity costs and a stagnant copper market, the operator has perforce devoted his attention to keeping his costs as low as possible with the equipment already installed. This does not mean, of course, that research and progress have halted—in fact, everywhere is evidenced the keenest interest in comparative performances.

Crushing and grinding account for the greater part of the expense of concentration, and consequently this department is attacked oftenest by well-intentioned economists. Gyratory crushers seem to be the favorite for coarse crushing—mammoth machines are in operation which receive 70-ton carloads of rock at a time, the size of the pieces being limited only by that which can be juggled on a steam shovel dipper. Doubtless it is cheaper to crush in gyratories than to blast in the mine, but a logical crusher to balance heavy shovels requires openings up to 8 ft. in width. Air-dumped steel cars of the type developed for short-haul railway excavation are favored in recent developments; however, Utah Copper, with its comparatively long haul, still retains its older drop-bottom gondolas. At best such a car unloads slowly and with great labor expense, so in order to save in unloading cost as well as to handle partly frozen ore, that company started operation at its Arthur mill of a new primary crushing plant. A carload of ore from the mine is pushed up an incline by an electric "mule," is clamped down into a cradle, and cradle, car and contents are lifted bodily, tilting sidewise about a pivot several feet above the rail. Ore drops from the overturned car on a huge grizzly made of I-beams and rails, and thence slides into the bell of the coarse crusher. All subsequent handling and elevating ending at the mill-feed bins are done by an elaborate system of inclined conveyors.

For the second stage in size reduction two machines are the favorites, rolls and disk crushers. The latter type particularly has been favored in leaching practice, where uniform size and a minimum of fines are desired. With Symons disks it is possible to eliminate screens, since the machine delivers pieces with one dimension constant. However, large flat pieces will be passed. In case the ore does not break into slabs, this characteristic of the disk crusher is naturally a considerable advantage over rolls, from which pieces with three variable dimensions will come. However, the extreme simplicity and tremendous capacity of large Garfield rolls in many cases will incline the balance of favor to their side.

Two types of vibrating screens have been developed, the Mitchell, used by Utah Copper, and Tyler's "Hummer," installed for trial at a number of places. Botn are electrically driven, actuated by the rotation of a tightly enclosed and somewhat unbalanced motor. As high as 3600 vibrations per minute can be given a taut screen surface by such means, their capacity on dry or wet material is tremendous, and if they can handle damp, sticky ore at a reasonable cost, they will surely find a welcome in the crushing field.

For finer crushing the ball mill has undoubtedly come to stay, although LENNOX at the Portland mill believes that Chilean mills have fallen into disrepute largely because they have habitually been given the wrong kind of feed. Like the ball mills at Inspiration, very much better performances in all respects can be had by giving Chileans a certain amount of relatively coarse material. New Cornelia, in its 500-ton experimental flotation plant at Ajo, is equipped for comparative tests on a special 8 ft. x 36 in. Hardinge conical mill, equipped with grates and with a large open discharge, and two rod mills designed by DAVID COLE, 42 in. x 9 ft. 8 in. and 60 in. x 10 ft. respectively. Rod mills are receiving their share of attention; thus at Nocazari favorable results as to power consumption and tonnage have been had from one designed by MARCY. In passing, one is reminded of the open-end mill tested a couple of years ago at Anaconda, where an old tube mill shell had a tire placed around the open end, and carried on double rolls from a disused drier. Metallurgically the results were excellent, giving a high tonnage at more uniform discharge, with less fines, two-thirds the steel consumption and 60 per cent of the power used in the current practice. The mill was abandoned, however, due to mechanical troubles incident to rapid rotation of such heavy masses in makeshift bearings. It is probable that the rod mill may not be able to crush coarse material in one step, but for grinding from, say, $\frac{3}{4}$ in. to 20 mesh and with the production of a uniform product, the open-end rod mill has extremely attractive possibilities.

In ball-mill crushing the cost of the grinding medium is one of the two large items of expense, the other being power. Metallographical investigations into the nature of steels used for balls and linings should improve this material to a surprising extent. Screening during stage crushing is also a most important item of cost. In order to economize at this point, dry crushing of ores from $\frac{3}{4}$ in. to 20 mesh has been tried at two localities in Arizona, in both rod and ball mill, but as yet without success.

As little is known about the fundamental laws of flotation now as a year ago. All mill experimentation, therefore, is empirical, and directed toward increasing recoveries at lower costs, by trying different combinations of oils, reagents and equipment. Very good results have been had with a combination of 60 per cent "X-cake" (alphanaphthylamine) and 40 per cent xylidine, both coal-tar products. In one plant the use of $\frac{1}{2}$ lb. per ton—of which a third is recovered—is producing a tailing containing 0.15 per cent sulphide copper, and a deflocculated granular concentrate which builds up $1\frac{1}{2}$ in. thick on an ordinary drum filter. It is impossible to draw general conclusions from isolated results in this dark corner of metallurgical practice, however, since ores vary so much in character from mine to mine, and even from one part of the same ore body to another. Still, many good reports are circulating about coal-tar products, and there is no doubt that the choice of oil has an important bearing on the recovery and grade of concentrates. It is doubtful whether these new combinations will free the users from the shadow of Minerals Separation, since they probably can be legally defined as "oils," and Messrs. SULMAN, BALLOT et al. control patents covering the use of soluble oils.

In pneumatic flotation the power required to compress the air is the largest single item of expense, and plant layout and porous-bottom construction to reduce frictional head to the minimum should merit closest scrutiny. While canvas or twill remains the favorite, concrete bottoms have given most encouraging results

at Ray Consolidated, while bricks of bakelite and sand, and other porous materials are constantly being tried. In many cases, air pressure can be reduced by using a thin bed of pulp in the flotation machine, the area of the flotation cells may be reduced by judicious intermediate classification, and recoveries may be increased by an efficient primary agitator to mix thoroughly the oil into the pulp. Mixing oil, acid and pulp by an elevator is in general an expensive method, requiring gunmetal buckets, lead-covered pulleys, and a belt renewal after six months.

Tables have by no means vanished, in fact the new Plato table has been given much attention and tried with many different shapes and kinds of riffles. Tables of some sort will be seen in flotation mills for many years to come, roughing high-grade feed and catching coarse mineral in tails.

Catalyst for the Oxidation of Ammonia

DEFERENCE to the article appearing elsewhere in this issue will show that, although the urgent need of adequate catalysts for preparation of nitric acid in the war industries no longer exists, we may, nevertheless, expect the work will be carried on to ultimate perfection, for adaptation to peace-time manufacture. The results of long experimentation carried to partial completion within the last few months have brought to us a wider vision of the large work that is yet to be done. We may well hope for still greater achievements from the scientists both here and abroad in the near future.

The generous manner in which these investigators are making public the conclusions arrived at from their exhaustive research, and the frank and open discussions resulting therefrom, will lead only to the attainment of the true ideal—the greatest benefit to the greatest number in everything that's chemical.

Efficiency and Morale Of Steel Mill Labor

IT IS a familiar dictum that shortage of labor encourages the introduction of labor-saving machinery. There is a general shortage of labor in the United States now and there will be for several years to come unless capital emigrates in tremendous volume or withdraws very largely from investment. Shortage of labor and abundance of capital are interchangeable terms to a greater extent than is commonly recognized.

In the circumstance of there being a shortage of labor one might be disposed to jump to the conclusion that the chief duty of steel mill managements at this time is to devote their attention to the introduction of additional labor-saving devices. There is ground for argument that this is not the correct deduction from the circumstances. Before the strike of September 22 the production of steel was not equal to the actual capacity of the steel-making units in operation, rating them according to performance in the past, say in the year 1916. There may have been some shortage of labor at that time, in point of numbers, but the common complaint was that labor was not performing efficiently. In the past few weeks the production of steel has been far below what it should have been in proportion to the number of men in employment. It is the commonly expressed opinion to-day that for some indefinite time to come steel mill labor will be below par in efficiency and morale.

Obviously this is not a condition that can be remedied by the introduction of additional labor-saving machinery. The condition is rather that on account of the human element the machinery is not producing as it is physically capable of producing. The remedy is to be sought not in additional or modified machinery but in a change in the attitude and performance of the workmen in the steel mills.

Since the inception of the strike of last September much has been said of the ignorant foreigner employed in the steel mills, ignorant even of the language. There has been much talk of the necessity of "Americanizing" him. It certainly follows that if steel mill labor in the past has been largely ignorant of the language, and in the future is to be more familiar with it, there is opportunity to arrange that the labor shall in future work more intelligently and efficiently.

The chief problem, then, seems to be not to improve the machinery of the steel mill, but to improve the men's handling of the machinery. It is not a problem of machinery, but a problem of men. In this day of labor shortage steel mill managements should not follow the dictum cited and study machinery and mechanical possibilities, but should study men and the possibilities of enabling them to do better work with the machinery already provided.

It may be that in the past "payment by results" has been carried in steel mills as far as it could be carried with the various descriptions of men that were at work. As many men, perhaps, have been given tonnage jobs as could understand the essence of a tonnage job, the more tons the more pay, and were sufficiently in touch with the management to have confidence that the pay envelope really represented the performance. Even granting that such has been the case, though there is room for doubt whether payment by results has been extended as far as it could be with the conditions of the past, it is clear that if there is to be, as there certainly must be, an increase in the intelligence of the men and a greater ability to understand the foreman or superintendent, a closer touch between the management and the workmen, payment by results can be extended.

Payment by results is not as popular as it should be on theoretical grounds, and one may venture to assert that the principle would be much more popular to-day if in years past so many employers had not abused the thing in practice. Often employers have cheated men directly and have swindled them by offering piece rates which were reduced when the men furnished more of the goods bargained for than had been expected. The main thing wrong with piece work has been the employers. The steel industry has its own principles and morals well established that when it offers piece rates or payment by results it treats its workmen fairly. There have been quarrels on this subject only when the men wanted to treat the management unfairly, when they refused to accept a reduction in tonnage rates when the tonnage increased not by the efforts of the workmen but by the investment of greater capital in improved machinery. The steel industry now has an opportunity to increase labor performance greatly by getting in closer and more intelligent touch with its workmen and by extending the system of payment by results. That is the rational way to improve the efficiency and morale of the men.

Western Chemical and Metallurgical Field

Chloride Volatilization Experiments on Ore From Tintic District, Utah

THE chloride volatilization process for the recovery of metals from ores that cannot be economically treated by usual metallurgical methods has received considerable attention during the last few years; there are at present, however, no commercially successful installations in operation in which the recovery of the metals is dependent upon the volatilization of these metals as chlorides. Laboratory investigations have almost invariably indicated that an economical recovery should be possible. In semi-commercial experiments difficulties have been encountered, more particularly with the roasting operation. The recovery of the fume has been successfully accomplished by means of bag-houses or by electrical precipitation, but, again, the treatment of the fume has presented difficulties. The practical solution of the entire problem will undoubtedly come with the development of apparatus designed to carry out the particular metallurgical and chemical reactions. Apparently standardized equipment cannot be modified so as to produce a practical unit that will perform its function in this metallurgical scheme with entire satisfaction.

A great deal of experimental work has been done on an ore from the Tintic district at Eureka, Utah, that has indicated the difficulties encountered, and the practical solution of some of these has been obtained. This is an oxidized siliceous ore containing lead, silver and zinc. It occurs as a replacement in limestone and is of a type which cannot be successfully treated by any developed metallurgical method. The ore is so highly siliceous that a pyrometallurgical treatment is impossible; the high lime content makes a hydrometallurgical method using an acid leaching solution uneconomical unless acid can be made on the plant. The average analysis of the ore is: Insoluble 62 per cent, lime 5 per cent, lead 8 per cent, zinc 2 per cent, silver 15 oz., and gold 0.1 oz. per ton. This ore is too low in lead and too high in silica for direct smelting except perhaps by mixing in limited amounts with a basic ore. It contains about 15 per cent of acid-consuming constituents. The physical characteristics are such that it cannot be successfully concentrated by wet methods or by flotation. These facts led to experimentation in order to determine whether the chloride volatilization method would be practical. A variation in this method as usually conceived was the idea of depending entirely upon the volatilization of the metals as chloride.

The ore was ground to 20 mesh, mixed with 10 per cent by weight of salt and roasted in scorifiers in an assay muffle. As a result of twenty tests on representative ore samples the following approximate volatilizations were obtained: Au 90 per cent, Ag 91 per cent, Pb 87 per cent, Zn 72 per cent. Average analysis of the ore and the calcine follows:

	Oz. per Ton		Per Cent	
	Au	Ag	Pb	Zn
Ore	0.10	8.9	3.92	2.9
Calcine	Trace	0.8	0.52	0.8

Recoveries obtained from similar tests upon representative ore samples from a different part of the mine were Au 80 per cent, Ag 74 per cent, Pb 98 per cent, Zn 53 per cent, with the following average analysis of the ore and calcine:

	Oz. per Ton		Per Cent	
	Au	Ag	Pb	Zn
Ore	0.080	20.9	17.3	5.8
Calcine	0.016	5.4	0.4	2.7

Experiments were made to determine the effect of calcium chloride and mixtures of calcium and sodium chloride in various ratios upon the rate and completeness of the volatilization and also the effect of the ratio of the chlorides to the ore. The results of these tests show that where salt is used as the chloridizing agent there is a tendency of the ore to sinter which becomes more noticeable with increasing amounts of lead in the ore. With calcium chloride the tendency to sinter is not as noticeable with the high-lead ores. The best results were obtained when using a mixture of two parts of calcium chloride to one part of salt. Early sintering causes a low volatilization of all the metals.

It was found that an oxidizing atmosphere is absolutely essential in order to obtain satisfactory volatilization of the silver. With the lead, volatilization took place as well in a neutral or reducing as in an oxidizing atmosphere. Pure silver chloride alone is practically non-volatile at the temperature maintained in the furnace or at about 850 deg. In the presence of lead chloride and sodium or calcium chloride it is, however, volatile at this temperature. It is claimed that $AuCl_3$ is decomposed at about 850 deg. C.; the recovery of gold from the fume indicates that the gold may be volatilized as a complex compound, since it is present in the fume as chloride and as metal. The amount of salt, calcium chloride or mixture of the two that produced the best results was found to be approximately 10 per cent of the weight of the ore. With ores containing 15 to 20 per cent lead this amount should be increased, but in any case the proportion to be used must be determined by experiment. Magnesium chloride acts similarly to calcium chloride.

Sintering

The tendency to sinter increases with the fineness of the grinding and with the amount of lead in the ore. The combination of a high lead content with salt as a chloridizing agent was particularly favorable to sintering. This is probably due to the reaction

$$PbCO_3 + 2NaCl + SiO_2 = PbCl_2 + Na_2SiO_3 + CO_2$$

Sodium silicate has a melting point below the temperature at which it is necessary to maintain the furnace charge. Other reactions which tend to take place are

$$2NaCL + O + SiO_2 = Na_2SiO_3 + Cl_2$$

$$2NaCl + H_2O + SiO_2 = Na_2SiO_3 + 2HCl$$

This last reaction takes place fairly rapidly, but can be prevented by proper control of the furnace temperature, while the other reactions proceed more slowly. Addition of lime rock tends to prevent sintering at the furnace temperatures, since lime-soda silicates tend to form and with proper control of furnace conditions this reaction does not proceed far enough to produce a viscous slag. If the volatilization roast be preceded by an oxidizing roast, sintering is to a large extent prevented. Obviously, these reactions do not take place where calcium chloride is used. The preceding reactions are given to show the manner in which sodium silicates are formed. Experimental work has shown that silica is not required for volatilization of the metals.

The results obtained from these experiments war-

ranted the testing of the process on a semi-commercial scale. A small reverberatory furnace was constructed, but did not prove to be satisfactory in operation. In order to volatilize even half of the silver very active hand rabbling had to be resorted to. This was attributed to the incomplete chloridizing, to the difficulty of maintaining proper temperature and particularly to the impossibility of maintaining an atmosphere duplicating muffle conditions. Further tests were made using a rotary kiln and more encouraging results were obtained; the capacity was, however, too low for commercial application. There was a tendency to form a nose ring at the feed-end of the kiln due to the moisture in the incoming ore. Nose rings at the fire end were formed by overheating of the charge. As the standard kiln is fired only at one end, the best operating temperature could not be attained in all parts of the furnace.

Fume from the kiln was passed through cooling pipes to a bag-house. The temperature was not reduced sufficiently to condense moisture on the bags since as the result of the reaction with zinc chloride, hydrochloric acid would be produced. New bags allowed the escape of fumes but not in sufficient amount to condemn the method. Electrical precipitation has been used to recover a similar fume at the Salt Lake City station of the Bureau of Mines, with practically complete recovery of the fume.

Treatment of the Fume

The fume contains lead, silver and zinc as chlorides, gold as chloride and metal, and in addition sodium and calcium chlorides. If copper were present in the ore, it will also be present in the fume as a chloride. Several methods for the recovery of the metals are possible. Zinc and copper can be removed by leaching with water, this will also remove a portion of the lead. The gold, silver and the remaining lead can then be reduced to bullion by fusion with lime and coke.

$$PbCl_2 + CaO + C = Pb + CaCl_2 + CO$$

This reaction will take place in the absence of silica, which latter if present will cause a re-volatilization of the lead. Copper and any silver or gold that may be extracted by the leaching solution can be precipitated on iron. By this method the chlorine is recovered in a form that can be again used in the volatilizing roast.

If the fume cannot be treated directly in the above manner, it may be leached with hot water, or better with a saturated solution of salt, and the lead recovered by one of several methods. If the solution be concentrated, quite pure $PbCl_2$ will crystallize on cooling and the residue can be treated by the fusion method; or this solution can be electrolyzed with soluble iron anodes. Complete precipitation of the metals is possible by boiling with sponge iron. The residue can then be smelted.

Continuation of the investigation with this particular ore and the development plans for a plant to treat the ore by the volatilization method in commercial quantities were temporarily suspended because of the development of ore on the property that was amenable to standard methods of concentration.

Work of a similar nature is being carried on at several experimental plants in the West, and by the Bureau of Mines station at Salt Lake City. Determination of the vapor pressure of silver chloride and investigations of the factors controlling its volatilization at furnace temperatures are now being conducted at the Berkeley station of the Bureau of Mines.

Meeting of Chicago Section American Chemical Society

AT THE Dec. 19 meeting of the Chicago Section, A. C. S., Dr. Hoskins called to the attention of the Section a circular letter which has been issued from the national secretary's office relative to H.R. Bill No. 8078, known as the Longworth bill. This letter contains a request that each individual member of the American Chemical Society communicate personally with Lawrence Y. Sherman and Medill McCormick, Senators, with the request that they use their efforts to make the bill a law. He also read a letter from Dr. Stieglitz, who is in New York, urging the members to communicate with these Senators. If this bill is not passed within a short time Germany could ship a quantity of vat dyes and organic chemicals sufficient to permanently discourage manufacture in the United States. This condition would be further aggravated by the present exchange rates, as the quotations are in German marks. Dr. Hoskins exhorted the members of the local Section to comply with the secretary's request.

Will Limit Chemical Importations

Dr. Redman, chairman, emphasized the fact that this bill will practically prohibit the importation of organic chemicals from *any* foreign country to the United States in all instances where the compound may be obtained in this country at a fair price for a good quality. The bill virtually gives a few years for the development of the industry and covers many chemicals. As these chemicals are also of vital importance in time of war it becomes a national and patriotic measure.

The paper of the evening was "The Business Side of Chemistry," presented by Otto Eisenschiml. His remarks, which are given in part herewith, are well worth the consideration of every man in the chemical and engineering profession.

The Business Side of Chemistry; Some Ideas on the Selling of Chemical Knowledge

Our colleges dismiss their graduates with the impression that their earning power will be in direct ratio to knowledge and chemical ability. That is not so. Chemical knowledge must be sold, and in order to bring handsome returns, must be sold cleverly.

I often wonder if our colleges, training men for chemistry without regard of their future prospects, are aware of the heavy moral responsibility that rests on their shoulders.

I do not blame the colleges for not giving courses in salesmanship of chemical knowledge. I doubt if there is anyone in the colleges who is capable of teaching this.

Business courses would not help the matter, as the graduate will learn this soon enough in his contact after graduation. I do blame the colleges, however, for failing to point out to their students that such salesmanship is essential to their progress.

To acquire chemical knowledge and use it for the common good is a worthy idea. There is nothing, however, in the law of the land or in the ethics of the profession to interfere with one's desire to obtain financial independence at fifty. Assuming that most chemists will live their lives in positions, have they not the right to fair recompense? Are we, like the owls in Athens, supposed to live on nothing but our wisdom?

It is reported throughout the country that professional chemists of caliber are taking up business pursuits in order to provide the wherewithal for decent living. If such a movement should take on large proportions it would be alarming and detrimental to the best interests of civilization. This consideration should bring a discussion on compensation for chemical service above the level of general discussions on money matters.

I have been criticized and ridiculed for discussing the possibility of reducing the number of chemists by disseminating facts among students regarding the true earning power of our profession. Is it more desirable to have men of forty quit in disgust and despair than to give a prospective chemist an inside tip on his future business prospect?

A man may decide to sacrifice his life on the altar of science, but he has no right to sacrifice his wife and children likewise.

Problem a National One

The problem is a national one, and I believe it can be corrected through proper publicity. I would not recommend a specific remedy at the first discussion. But the younger chemist should know that he is going to be up against it after leaving college. I believe in holding the number down to a minimum, not by law or regulation, but by previous advice to the undergraduates. The colleges are responsible for flooding the markets.

Most chemists hold good hands and play them like amateurs. Most business men hold nothing but a small pair and take the pot. The graduate starts wrong by accepting too low a salary for his first position. Most employers are willing to allot any salary and leave it to the man to make good. If he starts at $60 per month, he is forever handicapped. Every chemist who rings a time clock rings his own death knell.

The main thing is to get started right. It is not impossible because of present precedents to get a large salary on the start. If a man can sell shoestrings he can sell chemistry. The trouble with the present graduate is that he does not know how to meet men and market his services. He lacks the knack of salesmanship.

Lack of Business Knowledge the Trouble

Next to starting wrong the promotion in existing positions is very hard. Business knowledge is a mystery to the chemist. That's the trouble! It is easy to learn business, because it is just common sense. To sell a chemical formula to a layman is unfair to both buyer and seller. To sell a chemical service together with a formula is good ethics and very good business. A chemist that does not know the market value of every ingredient he handles is a failure. He can never expect to be more than a servant of industry.

Nothing is gained by the everlasting wail that chemistry is an underpaid profession. The law of supply and demand listens to no moral arguments, no matter how plausible. A laboratory chemist is generally paid merely for collecting facts, and he can expect no high pay for this service. The man that correlates these data and draws the business conclusions is the one that reaps the harvest. Chemists often furnish advice to business men on which the business men make one hundred times the amount of the fee. It is peculiar that so few chemists are willing to take the risk of financing their own devices.

I suggest only individual changes and no revolutionary movement. There is no reason why one brain cannot hold both common sense and applied chemistry.

Discussion

The paper was very heartily received by the Section and a number of approving speeches followed. Mr. McCoy stated that Mr. Eisenschiml's remarks were excellent and to the point. It is a question of salesmanship and also service to the employer. He must show the manufacturer that he is bringing returns to the company.

Dr. Wesson, who has recently been elected president of the American Institute of Chemical Engineers, stated that if he could have met Dr. Eisenschiml twenty-five years ago it would have been money in his pocket. The chemist must demonstrate to future employers that he is an asset rather than a liability.

Mr. Williams voiced the sentiments of Mr. Eisenschiml. He stated that an engineering course and chemical course are the same in that they lead to anything if you quit soon enough.

New Jersey Clay Workers Hold Annual Meeting

The annual meeting of the New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society has grown to be one of the important events of the year in ceramic circles in this section, and the gathering at New Brunswick, N. J., on Dec. 18 emphasized this impression. Close to seventy members and guests were present at the morning and afternoon sessions, held in the Fine Arts Room, Queens Building, Rutgers College.

The morning session was given over to general business and the presentation of two papers, the first an impressive talk by Charles Howell Cook, president of the Cook Pottery Co., Trenton, N. J., and chairman of the association during the past year, on the subject of "Preparing for Future Competition." He set forth the urgent necessity for the American manufacturer to be watchful of the inroads being made in the importation of ceramic and other wares to this country from England, Germany, Japan, China and other countries. He gave an interesting piece of information that a ceramic school was now operative in China, with a Japanese, educated in the United States, as director.

The other paper was an instructive lecture by Homer F. Staley, Bureau of Standards, Washington, D. C., on "Feldspar as a Pottery Material." The paper covered the composition of pure feldspars, their geological occurrence, winning and preparation, grading and chemical analyses. Reference was made also to the mineral composition of well-known feldspars, and methods of testing and blending. In a summary of the subject, substitutes for this material in pottery production were mentioned, including the most popular, Cornwall stone, white mica and talc.

The afternoon meeting, coming to order after an enjoyable luncheon at the Hotel Kline, was devoted to a broad discussion of fuel. Three important papers on this subject were presented, "Fuel Analyses," by A. C. Fieldner, supervising chemist, Bureau of Mines Experiment Station, Pittsburgh, Pa.; "Oil Burning in a Ceramic Plant," by R. L. Clare, Federal Terra Cotta Co., Woodbridge, N. J.; and "A New Type of Producer-Gas Fire Box," by R. H. Minton, General Ceramics Co., Metuchen, N. J.

Mr. Fieldner's paper was a comprehensive résumé of methods in use for analyzing coal, covering sampling, proximate analysis, ultimate analysis, determination of heating value, fusibility of ash and a survey of the fusibility of ash of American coals. Information was also given regarding a calculation of heating value and ultimate analysis from moisture and ash determination.

Other papers given at the afternoon meeting were "Properties of Pottery Bodies and Glazes," by H. G. Schurecht, Bureau of Mines, Mining Experiment station, Columbus, Ohio, and the "Furnace Gas Producer," by Charles W. Parks, ceramic engineer, International Clay Machinery Co., Dayton, Ohio. Mr. Schurecht's paper was a technical treatise on pottery bodies, embracing such data as elutriation tests on kaolins, the effect of electrolytes, grinding, screening and organic additions on bodies, refractories, coefficient of expansion of bodies, crazing of glazes with special reference to coefficient of expansion, luster decorations for pottery and adventurine glazes.

At the annual election of officers, the following were appointed for the coming year: Abel Hansen, head of the Fords Porcelain Works, Perth Amboy, N. J., chairman; C. S. Maddock, Jr., of the Thomas Maddock's Sons Co., Trenton, N. J., vice-chairman; Charles A. Bloomfield, head of the Bloomfield Clay Co., Metuchen, N. J., counselor; Charles Howell Cook, Trenton, chairman of executive committee; and George H. Brown, director, department of ceramics, Rutgers College, New Brunswick, secretary and treasurer.

Officers of the Iowa Section, A. C. S.

The officers of the Iowa Section of the American Chemical Society for the coming year have been elected as follows: President, W. S. Hendrixson, Grinnell, Iowa; vice-president, P. A. Bond, Iowa City; counselor, R. M. McKenzie, Fairfield; secretary-treasurer, F. S. Mortimer, Iowa City.

American Metal Buys Vogelstein

The American Metal Co. has acquired the entire business of L. Vogelstein & Co. The purchase gives the American Metal Co., which has heretofore been mainly interested in zinc, lead and minor metals, a prominent place in the copper market, as the business of L. Vogelstein & Co. was mainly done in this metal.

Among the assets of the Vogelstein company taken over by the American Metal Co. is the copper refinery at Chrome, N. J., in which Vogelstein up to recently had a minority interest. He now has the controlling interest by purchase from the United States Smelting, Refining & Mining Co.

Mr. Vogelstein acquired a substantial interest in the American Metal Co. at the recent sale of metal company shares held by the Alien Property Custodian. Other purchasers of shares at the same time were the Cerro de Pasco Copper Co., J. Horace Harding, Louis T. Haggin, Charles D. Barney & Co. and others affiliated with the Cerro de Pasco Co.

Annual Dinner of the Chemical Warfare Service

The second annual dinner of the Chemical Warfare Service was held at the New Ebbitt Hotel, Washington, D. C., Friday, Jan. 2, 1920. The dining room was appropriately decorated with small colored balloons filled with hydrogen and attached to each plate. About 150 officers and ex-officers of the service were present.

Members of the service took advantage of the occasion to express their appreciation of Major-General Sibert, director of the Chemical Warfare Service, through the presentation of a large reading lamp of unusual design. The base was of carved wood, while the standard was a 75-mm. gas shell, with a cluster of lamps at the top. Lieutenant-Colonel Amos A. Fries presided as toastmaster; responses were made by Major Brown, Colonel Ellicott, Major Woods, Major Sutherland, General Sibert and H. C. Parmelee. Major H. S. Kimberly was chairman of the general committee.

ANNUAL DINNER CHEMICAL WARFARE SERVICE, WASHINGTON, D. C., JAN. 2, 1920

British Chemical Industry

(From our London correspondent)

INDUSTRIAL conditions seem to be becoming more stable as the international labor situations are taking more definite shape, although the change over from war to peace programs created uncertainty, especially among the smaller firms. The export trade continues to be very active and the home trade is also improving. The American coal strike has naturally contributed to this. The need of increased capital to meet new conditions is illustrated by the great increase in new capital issues. The formation of trade associations still continues, while among the manufacturers of chemicals considerable activity is being shown in new types of plant and apparatus, some of which originate in the United States and for which catalogues and advertisements are issued at frequent intervals. Standardization of plant, detail fittings, and even of pipework and stoneware is still conspicuous by its absence. The coal situation continues to be interesting and if, as is probable, the price can be reduced, this will give a considerable stimulus to the chemical industry.

Two Valuable Reports

In the industrial field interest has centered on the report recently issued by the Factories Branch of the Department of Explosives Supply and on the somewhat overdue final report of the Nitrogen Products Committee. The former gives valuable information on factory records and cost systems presented in such a way that the individual manufacturer can adapt them to his own requirements. The latter will be published shortly and comprises several hundred pages of carefully compiled information and data covering the whole nitrogen field and making all necessary recommendations regarding the future requirements of the British Empire. The general nitrogen situation has been ably reviewed in the technical press by Dr. Maxted and a decision must soon be made in regard to the future of the Haber and cyanamide processes.

Government to Sell Nitrate Plant

It is, of course, common knowledge that the British Government had started to build a Haber nitrate plant at Billingham-on-Tees, Yorkshire, and that when work ceased there soon after the armistice, the buildings had not progressed much further than their foundations, though a good deal of plant was on the site or on order. The government now by advertisement invites offers for the purchase of the factory at private sale, and it is known that a leading British firm, probably in conjunction with firms having linked interests, has made an offer. As it has just been officially announced that licenses have been granted to Brunner, Mond & Co. to operate certain Badische and Haber patents, it seems certain that this is the firm in question, particularly as the necessary capital is available owing to the sale for cash to Lever Bros., Ltd., of Brunner, Mond & Co.'s controlling interest in Crosfield's and Gossage's soap works.

As regards dyes, licenses have just been granted to Morton Sundour Fabrics, Ltd., to operate various patents of the Badische, Bayer, Griesheim and other German dyeworks.

The anti-dumping bill is likely to give rise to much controversy and is viewed with considerable misgiving in some quarters.

The new president of the Society of Chemical Industry, John Gray, of Lever Bros., Ltd., seems to be infusing new life and increased vigor into its activities. The new Chemical Engineering Group already comprises nearly 700 members and is to hold conferences and symposiums on appliances for moving liquids, and on labor-saving devices in chemical works, at Newcastle and Birmingham respectively. For the latter, American specialties will no doubt predominate, and owing to the increased cost of labor, there should be an active demand for them among British manufacturers. Turning to the social side, which has been sadly neglected over here in the past, the Chemical Industry Club is playing an important part and the recent first annual dinner of the club, which now has over 700 members, was a notable occasion. Reciprocal membership has been arranged with the Chemists' Club of New York and many Americans have already made use of the facilities offered.

Dr. J. Gordon Parker has been elected president of the International Association of Leather Trades Chemists, the next conference of which will be held in London in 1921. A new chair of applied physics is to be founded at Glasgow University, while courses and lectures in chemical engineering are being arranged at many universities and technical colleges.

The Shawinigan Co. of Canada has founded a branch company, Shawinigan, Ltd., at 1 Tudor St., London, E. C., 4, for the sale of its products.

Bureau of Standards Plans Increase in Chemical Activities

Congress has been asked for nearly $3,000,000 to carry out the program of the Bureau of Standards during the next fiscal year. The plan includes the expansion of many of the chemical activities of the Bureau. The items of interest to chemists are as follows: For testing chemicals, varnishes, soap materials and inks, $50,000 (an increase of $20,000 over the current appropriation); to study methods of measurements and technical processes used in the manufacture of pottery, brick, tile and other clay products, $50,000 (an increase of $30,000); to determine experimentally important physical constants of materials essential to the industries or in laboratory investigation, such as the determination of the value of gravity, thermal conductivities of material, mechanical equivalent of heat, metallurgical constants (such as specific and latent heats of metals and alloys), the electrochemical equivalent of metals, and the velocity of light, $25,000 (an increase of $20,000); for purchase, preparation, analysis and distribution of standard materials to be used in checking chemical analyses and in testing of physical measuring apparatus, $15,000 (an increase of $10,000); for the investigation of the problem involved in the electrodeposition of metals, $20,000; for investigation, aiming at improvement in the quality of reagents used in chemical analysis and their eventual standardization, $15,000; for the equipment, maintenance and operation of a low temperature laboratory, including the production of extremely low temperatures, the establishment of the low temperature scale, the production of liquefied gases, and the separation of the constituents of air and other gaseous mixtures, the development of containers and other equipment for liquefied gases, and the application of liquefied gases and low temperature investigations to aviation, $20,000.

Inaccuracy of Treating Records Due to Moisture in Wood

Description of the Experimental Work to Determine the Reactions Taking Place in the Treatment of Wood With Inorganic Salt Preservatives — Record of Tests, Discussion of the Results and Conclusions

BY ERNEST BATEMAN*

IN STUDYING the effect of leaching on wood treated with inorganic salt preservatives, such as zinc chloride, copper sulphate, zinc sulphate, cresol-calcium, etc., it has frequently been noticed that the treating record did not check at all closely with the amount of salt found to be present in the wood. The treating record consisted in the weight of the piece before and after treatment, the difference between the two being considered as the amount of solution injected. This weight of solution multiplied by the per cent of concentration should give the amount of salt injected into the piece. Analysis of the wood after treatment frequently showed that there was often as much as 50 per cent more salt actually in the piece than the treating record showed should be the case and rarely if ever did the record and the analysis agree. In commercial practice the same phenomenon was noticed to a greater or less degree. The theory which has been advanced by wood preservers that there is a chemical union between zinc chloride and wood substance seems therefore to have some basis for its existence. If this is the case, then we must also attribute the increased absorption of such salts as zinc sulphate, copper sulphate, cresol-calcium, and, as will be shown in this paper, calcium chloride, to the same cause.

Experimental Determination of Wood Absorption of Inorganic Salt Preservatives

In order to throw some light on the subject small pieces of wood 2 x 2 x 8 in. were treated with zinc chloride solution and the solutions analyzed before and after treatment to determine if there was any change in the strength of solution. The amount of wood used was as great in proportion to the solution as it was possible to make it. Three conditions of wood were used, oven dry, air dry, and green. The analysis of the solutions showed that there was a change in the strength of solution during treatment, but the weakening of the solution was not in proportion to the amount of wood present in the three runs, and in one case no weakening at all was obtained. The results were such that no very definite conclusion could be drawn. It was therefore decided to make a much more comprehensive and detailed study of the treatment, but in place of zinc chloride to use calcium chloride, chiefly because calcium is much more readily and accurately determined than zinc and at the same time it resembles zinc chloride in its solubility, deliquescence, etc. A small treating cylinder was used, and here again, as in the previous case, the amount of wood was made as large as possible in comparison with the treating solution. The weighed wood was treated to refusal at a temperature of 180 deg. F. Three conditions of wood were again used, oven dry, air dry, and green; the first containing no moisture, the second 15 to 20 per cent, while the third had 30 per cent or more. Actual moisture determinations were not made. The solution was weighed before and after treatment, separate solution being used for each run. As soon after treatment as possible the wood was removed from the treating cylinder and placed in covered glass jars to drip and cool. These were then weighed after cooling. The difference in weight before treatment and the weight after treatment and cooling was taken as the treating record. The drip and condensate were also weighed.

The wood was allowed to dry to some extent and was then reduced to sawdust and analyzed for calcium. The method of analysis consisted in ashing a weighed portion of sawdust and determining the calcium volumetrically by means of its oxalate. The accompanying tables show the results obtained.

Found in wood		0.0873		0.0700		0.0695
Loss by difference		0.0037		0.0025		0.0000

Correction of Results

Although an attempt was made in this work to reduce the losses of both solutions and salt to as small a factor as possible, in spite of these precautions small losses did occur. It is almost impossible to pump 20 lb. of solution from a carboy to a treating cylinder, put it under pressure, heat it to 180 deg. F., then after the completion of treatment release the pressure and catch all the solution, and entirely prevent evaporation either from the wood or solution or both. For this reason a complete audit of the solution and salt was made so that these discrepancies could be corrected.

The discrepancies which appear in this work must

*Chemist in Forest Products Laboratory, Madison, Wis.

always be errors on the loss side and can be divided into two kinds:

1. Losses due to leaks and to transferring the solution,
2. Losses due to the evaporation of the solution because of its elevated temperature after treatment.

The former would cause a loss in both water and salt, the latter a loss of water only. Whenever we find that we have lost both water and salt in the same proportions, we are justified in assuming that this loss was due to a leak, and when we find that there was no loss of salt but a loss of water, we are justified in assuming that this loss was due entirely to evaporation either from the wood or from the solution. Where we have losses in both water and salt, but they do not check, then we can say that the loss of salt was due to leaks, while the loss of water in excess of this loss by leakage was due to evaporation.

Records of Run No. 1

The amount of solution before treatment was 21 9 lb. That accounted for after treatment was 21.7 lb., or a loss of 0.2 lb. The total amount of salt used was 0.4030 lb.; accounted for after treatment 0.3993 lb., or a loss of 0.0037 lb. The concentration of the solution before and after treatment was 1.84 per cent. A loss of 0.20 lb. by leakage would account for 0.0037 lb. of

TABLE III. CORRECTED RECORDS OF RUN NO. 1

Salt in wood found by analysis, 0.0873 lb.

salt, or the actual loss found by experiment. We can therefore conclude that there was a small leak in the apparatus, which passed unnoticed during the run.

There was no change in the strength of the solution during treatment, nevertheless the drip solution is noticeably weaker than either of the solutions. At the same time there is more calcium chloride in the stick than ought to have been there if the treating record is correct. The sticks, after removal from the treating cylinder, were placed while still hot under a bell jar to drip. The steam arising from the wood condensed on the jar and ran down into the drip solution with a consequent weakening of this solution. The amount of this condensate can easily be calculated. The record shows 0.58 lb. of 1.35 per cent solution as drip. The weight of this solution must therefore have been increased by the amount of water necessary to dilute a 1.84 per cent solution to 1.35 per cent or

$$\frac{1.35}{1.84} \times 0.58 = 0.425$$

That is, the actual drip was 0.43 lb., the remaining 0.15 lb. being moisture which evaporated from the wood during cooling. This should be added to the treating record as being absorbed by the wood. The corrected record then reads as in Table III.

Records of Run 3

In this run there was a loss of 0.89 lb. solution but no loss of salt. All the loss must therefore have been due to evaporation. This may have taken place from the wood or from the solution. It does not seem likely in this run that much of this loss could have

TABLE IV—CORRECTED RECORDS OF RUN NO. 3.

	Lb.	Lb.	Lb.

Salt in wood from analyses			0.0695
Difference excess over treating record			0.0233

taken place from the wood because of the short time exposed after treatment. It is known, however, that the stopper was left out of the carboy for some time after the hot solution had been put into it, so it seems likely that the loss occurred at this place. If it all took place here, then the treating record of the solution after treating should be 16.91 lb. instead of 15.77, and the concentration should be 1.66 instead of 1.78. Here again the drip solution is weaker than the solution after treatment and if we follow the same line of reasoning we can correct this $\frac{1.61}{1.69} \times 1.48 = 1.41$. Actual drip $1.48 - 1.41 = 0.07$ due to evaporation. The corrected record then reads as in Table IV.

Records of Run No. 2

In this run we have both a loss of salt and a loss of solution. The loss of salt amounted to 0.0025 lb. or 0.18 lb. of 1.41 per cent solution. The remaining loss, 0.40 lb., must have been evaporation. It seems more than likely that most of this evaporation took place

TABLE V. CORRECTED RECORDS OF RUN NO. 2

	Lb.	Lb.	Lb.

Salt in wood by analysis			0.0700
Excess over treating record			0.0106

from the wood itself, because in treating the pieces became wedged in the small cylinder and considerable difficulty was experienced in removing them. Furthermore, the concentration of the drip is greater than that of the solution after treatment. This could only be obtained by evaporation of moisture from the wood and a consequent removal of the more concentrated solution by washing with the drip. This would of course take place chiefly at the ends and would account for only a small part of the actual loss, since the concentrated solution caused by evaporation from the sides would not be removed by the drip. We are therefore justified in assuming that the loss by evaporation took place chiefly from the wood. On this basis the corrected treating records are as shown in Table V.

Discussion of Results

Table VI summarizes all the important corrected data in the three runs.

TABLE VI. SUMMARY OF CORRECTED DATA

	Oven Dry	Air Dry	Green
Wt. of wood, lb.	4.09	4.80	5.29
Amount of solution used, lb.	21.70	21.42	20.90
Strength of solution before treatment, per cent.	1.84	1.41	1.79
Strength of solution after treatment, per cent.	1.84	1.35	1.66
Change in strength of solution due to treatment, per cent.	0.00	0.06	0.13
Amount of salt injected:			
By analyses of wood	0.0873	0.0700	0.0695
By treating record	0.0872	0.0594	0.0462
Excess injected over T. R.	0.0001	0.0106	0.0233

In only one of these conditions does the treating record agree with the amount found by analysis, that is, the oven dry pieces. In this also the strength of the solution remained unchanged as a result of treatment. If there is any change in the concentration due to chemical affinity it ought also to be shown in this as well as in the two other cases. We can therefore discard the theory that the wood substances enter into a firm chemical union with the materials used in treating.

There is, however, a striking relation between the reduction in concentration of the treating solution, the apparent excess absorption of salt and the moisture content of the wood. With an increasing moisture content of the wood, the difference in concentration of the solutions before and after increases, and the excess salt found in the wood increases.

This leads to the conclusion that the moisture present in the wood acts as if it had actually been added to the solution and decreases its strength. In other words, the water present in the wood is replaced by solution. This solution would then escape measurement because an equal amount of water takes its place. The amounts of water necessary to cause the reduction in strength for the two solutions are respectively 0.85 lb. and 1.69 lb. Unfortunately, moisture determinations were not made, but the treatments were made with the same number of pieces of approximately the same dimension and same species, consequently the oven dry weight of all three runs should be approximately the same. We should be able to form some idea as to whether or not there could be present in the wood sufficient moisture to cause the phenomena noted. If we take the oven dry sticks as a basis of oven dry weight, we find that there was at least 0.71 lb. water in the air dry stick and 1.20 lb. water in the green stick, so that it is not unreasonable to suppose that the difference between these weights and that required may be due to shrinkage of wood, differences in density of wood substance, and differences in the size of the pieces. If we then subtract the amount of water required to dilute the solutions from the green weight of the wood before treatment, we should get the dry weight of the wood.

$$4.80 - 0.85 = 3.95 \text{ lb.}$$
$$5.29 - 1.64 = 3.65 \text{ lb.}$$

Subtracting these weights from the weight after treatment should give us the amount of diluted solution injected into the wood.

Run No. 2	Run No. 3
9.01	7.87
3.95	3.65
5.06 of 1.35 per cent	4.22 lb. of 1.66 per cent sol.

on a salt absorption of 0.0684 and 0.0701 respectively, actually found by analysis being 0.0700 and 0.0695 respectively. From this it would seem that the correct explanation of the phenomena noted is that the water in the wood acts as a diluent of the treating solution and gives a greater treatment than is apparent from the treating record.

Conclusions

The following conclusions can be drawn from this work:

a. There is no apparent reason to suppose that a chemical combination results from the treatment of wood with most inorganic salts, such as zinc chloride, zinc sulphate, sodium fluoride, calcium chloride, etc.

b. The moisture present in the wood at the time of treatment acts as diluent of the solution.

c. Any system of measuring the absorption of salt by wood during treatment which is based on a measurement of the weight or volume of the solution before and after treatment is liable to a very considerable error. Only when the wood is free from moisture are such measurements exact. At all other times either weight or volume measurements will be in error because of the exchange of the moisture in the wood for solution so that more solution will actually be injected than is made apparent from the treating records.

Action of Muriatic Acid on Manila Rope

At the instigation of the National Safety Council, an investigation has been undertaken by the Bureau of Standards, Department of Commerce, to determine the action of muriatic acid on manila rope. The effect of this acid or its fumes on rope of this kind is a great menace, as the acid weakens the rope seriously without any superficial trace of the action being noticeable to the eye. When rope is exposed to this acid, as, for instance, when it is used in blocks and falls of swinging staging when washing down brickwork, etc., many serious accidents have resulted, some of which have been fatal, owing to the fact that the rope has been weakened through contact with this acid or its fumes. The only practical remedy suggested is that of treatment of manila rope before using with some acid-resisting compound. An attempt will be made in this investigation to determine by testing the actual effect of the acid, and ascertain if the deterioration can be remedied by impregnating the rope with a certain compound which the National Safety Council advances as having been effective in protecting machinery and equipment from acid corrosion.

Present Status and Outlook of the Magnesium Industry

By J. T. Rooney, D.S.C.
Metallurgist, Norton Laboratories, Inc.

MANUFACTURE of metallic magnesium is one of those industries which owes its development in this country to conditions brought about by the war. The metal was first produced in England by Davy in 1808, but it was not until the early '60s that attempts were made to produce it on a commercial scale. In recent times, before the outbreak of the war, plants in England and particularly Germany supplied the world's demand for the metal. It was turned out chiefly in powdered form for photographic flashlights, pyrotechnical purposes, and to a small extent in ingot form as a deoxidizer of non-ferrous metals and for use in light alloys of aluminum.

Prior to 1914 the demand for magnesium in the United States was not sufficiently great to stimulate the production of the metal in this country, but the outbreak of hostilities in Europe, the cutting off of the supply from Germany, and the urgent requirements of the allied governments for the metal for military purposes, with consequent alluring prices, induced several firms to undertake its domestic production.

Plants were erected by the American Magnesium Corporation at Niagara Falls, N. Y.; by the Rumford Metal Co., at Rumford, Me.; by the General Electric Co., at Schenectady, N. Y.; by the Dow Chemical Co., at Midland, Mich.; and by the Norton Laboratories, Inc., at Lockport, N. Y., resulting in the production in 1915 of 87,500 lb., in 1916 of 75,400 lb., in 1917 of 115,813 lb.; and in 1918 of 284,188 lb.

Some of these plants closed down after a short period of operation, and practically all ceased production with the sudden termination of the demand when the armistice was signed, and unless new and extensive uses are found for the metal in the near future, most of these plants are destined for the scrap heap.

Preparation of the Metal

Magnesium has been prepared by a great variety of processes, i.e., reduction of the oxide with potassium, or with carbon at high temperatures; electrolysis of aqueous solutions of the salts; and electrolysis of the fused salts (usually the chloride) in admixture with salts of the alkalis or alkaline earths.

The method most generally in use and probably the most successful so far has been the electrolysis of fused magnesium chloride with the chlorides of potassium, sodium or calcium, but the scarcity of potash during the war precluded its use and compelled the substitution of other salts.

When the domestic production of the metal was undertaken, the only data obtainable on the subject were a few vague statements in textbooks, each prospective producer being compelled to work out his own method of manufacture independently, and consequently each process differed considerably in detail from the others, while some entirely new ones were developed. Still, the cost of producing the metal appears to have been about the same in all instances.

There can be little doubt that if the knowledge gained at the various plants by experience of the past few years was pooled, a much more efficient process could be evolved from the combined data than any heretofore existing and the prospect for a greater production of magnesium in the future would be considerably brightened, for while the metal continues to be sold at its present price its application to industry must necessarily be limited.

A favorable factor in the chloride electrolysis process is the possible utilization of the chlorine gas generated at the anodes for the manufacture of by-products, the value of which might materially offset the cost of production of the metal. The simultaneous manufacture of magnesium chloride and potassium chlorate by chlorination of magnesium oxide with waste furnace gases has, in the writer's experience, worked very satisfactorily.

In 1881 von Putner patented a process for obtaining magnesium by reduction of the oxide with carbonaceous matter and a little iron oxide in closed iron retorts heated to whiteness, the vaporized metal passing over into condensers, the process closely resembling the smelting of zinc. Reduction of the metal in this manner is possible because of the more unstable nature of magnesium carbide, which, unlike that of calcium, decomposes at such temperatures. The high cost and difficulty of obtaining the necessary heat were at that time the deterrents to the success of von Putner's method, but today with the ease and economy with which very high temperatures can be obtained by means of the electric furnace, adaptations readily come to mind which should give the process promising possibilities under modern conditions.

Occurrence of the Ores

Magnesium is said to form 2.24 per cent of the crust of the earth and the occurrence of its compounds are almost universal. Great deposits of dolomite, the double carbonate of calcium and magnesium, are very common. Magnesite, or magnesium carbonate, is mined extensively in Hungary, Greece, Canada, and in this country in California and Washington. Enormous quantities of carnallite, kieserite, and other magnesium minerals are available in the great salt beds of Strassfurt, Germany, and may possibly be found also in the deposits in Alsace.

Properties of the Metal

Magnesium has a greater affinity for oxygen than any of the common metals and combines very readily with it at high temperatures. Advantage is taken of this by employing it as a deoxidizer of metals in the foundry. When magnesium is finely divided it will, after ignition, burn with great violence, emitting a brilliant light rich in actinic rays, and is therefore much used for photographic flashlights and pyrotechnical purposes. These uses are likely to maintain a steady although limited demand for the metal.

Some of the more important physical properties of magnesium in comparison with those of aluminum and copper are given in the following table:

	Magnesium	Aluminum	Copper
Specific gravity	1.74	2.7	8.9
Melting point, deg. C.	651	658	1054
Boiling point, deg. C.	1120	1800	2310
Electrical resistivity, mic./cc.	4.35	2.8	1.58
Thermal conductivity	0.376	0.48	1.0405
Coeff. of expansion	.0000259	.0000222	.0000159
Tensile strength (cast), lb.	20,000	15,000	24,000
Elongation, per cent.	9	3	6

At temperatures around 450 deg. C., magnesium can be drawn, rolled, hammered or extruded with comparative ease.

Of course, the properties for which magnesium is chiefly valued as a metal are its low specific gravity and comparative strength, which properties appeal strongly to the modern engineering tendency to lightness in construction, particularly in the case of motor vehicles and aircraft. It is also a very superior bearing metal and has been shown to wear less than even cast iron under similar conditions of test. It machines beautifully, it being possible to cut the finest and sharpest of screw threads with ease and precision, and it is probable that the metal is superior to any other in this respect.

Magnesium, however, also possesses properties which are generally considered as disadvantageous to a metal under certain conditions. Dampness affects the metal, at least superficially; it is attacked by hot or saline waters; it is rapidly corroded by weak mineral or organic acids; and its soft nature renders it easily liable to injury by mechanical abrasion.

The high coefficient of expansion of magnesium may present a serious problem when the metal is used in assembly with other metals which are affected to a considerably lesser degree by varying temperature conditions.

Alloys

So-called aluminum-magnesium alloys have recently come into use, the magnesium contents of which are less than 1 per cent. It is altogether likely that the magnesium used in casting the metal is of greater value as a scavenger than by virtue of any properties imparted to the alloy by the amount retained.

Magnesium has been cast in aluminum in amounts up to 8 per cent, and some very excellent alloys of low specific gravity and great strength have been produced.

Magnesium alloys readily with practically all of the non-ferrous metals, but when the magnesium content exceeds 10 per cent, the binary alloys become, as a rule, brittle. Similarly, when another metal is alloyed with magnesium in amounts exceeding 10 per cent, these alloys also tend to become brittle.

In the development of useful alloys having magnesium as the predominating constituent, there is plenty of opportunity for research. The pure metal is rather difficult to cast, owing to the tendency to oxidation with inclusion of oxidized particles and because of excessive shrinkage. Binary alloys, generally, present the same difficulties as the virgin metal. But when two or more metals are alloyed with magnesium in lesser amounts, the shrinkage, as a rule, becomes very appreciably less, the hardness is increased, the elongation greatly reduced, the crystalline structure becomes very fine, and well-defined castings can be easily produced quite free from oxides or impurities.

Castings of motor pistons, connecting rods, and like parts have been made of magnesium alloyed with small amounts of other metals, and have given as satisfactory service as those of aluminum, with the added advantage of a considerable reduction in weight. As already pointed out, these alloys retain some of the defects as well as the virtues of the predominating constituent and in the case of motor pistons the high coefficient of expansion characteristic of aluminum and magnesium necessitates finishing the pistons considerably smaller in diameter than the inside of the cast-iron cylinders in order to avoid jamming by the greater expansion of the pistons when the parts are heated to operating temperatures. Thus, when the parts are cold, there is a clearance between the piston and cylinder which results in a loss in compression and sometimes difficulty in starting the motor. However, this is a condition which could possibly be alleviated by special design of the piston and rings.

The possibilities in the development of magnesium alloys of remarkable lightness and strength, together with the extensive occurrence of the ores, should offer every encouragement to metallurgists throughout the world for the evolution of a process for the production of the metal at a cost which would insure its application to industry on a scale commensurate with its admirable properties.

Economies of Electric Iron and Steel Production in Scandinavia*

By Joseph W. Richards

During a tour of Scandinavia this summer I was particularly interested in inspecting electric pig-iron furnaces, in which I have been interested for a great many years, and had the opportunity to see eleven out of the twelve furnaces which are in operation. The first plant visited was at Trollhättan, where the original Jernkontoret furnace of 1912 is still in operation.[1] Mr. E. Nystrom is in charge of the plant. A second has been built alongside of it. Both are being run very steadily and uniformly on a medium-grade iron ore, making a pig iron which is going into commercial use, using only charcoal as a fuel.

This may be said about the use of the electric furnace as compared with the blast-furnace in Sweden: At the present time, charcoal is cheaper than coke, and therefore it is cheaper to run with charcoal; the electric pig-iron furnace thus has the advantage of working at its best, under conditions where the blast-furnace can hardly compete with it. Pig iron produced by those furnaces is costing, in Sweden, about $5 per ton less than their own blast-furnace pig iron.

I hardly think that any more blast-furnaces will be built in Sweden. Possibly a few may be in certain localities, but wherever water power is available for producing electricity, certainly the electric pig-iron furnace can operate more cheaply in Sweden than the blast-furnace can.[2]

The next plant visited was at Domnarfvet. They have four furnaces,[3] three of which were in operation. The fourth was idle on account of shortage of water power, it being the dry season. These furnaces show very plainly the successive development of the electric furnace. The first electric pig-iron furnace in Sweden was erected in Domnarfvet; that first one has been torn down and a more modern one is being erected in its place.

---

*Following a session on Iron and Steel at the Chicago meeting of the American Institute of Mining and Metallurgical Engineers, at which he presided, Dr. Richards made these remarks regarding Electric Iron Smelting, as he found it.

[1] Met. & Chem. Eng., vol. 9, 1911, pp. 368, 459, 503; vol. 10, 1912, p. 413.

[2] For a discussion of details of electric smelting of iron ore, see Met. & Chem. Eng., vol. 12, 1914, pp. 82, 225, 444.

[3] Met. & Chem. Eng., vol. 16, p. 509.

The four other furnaces show four successive steps in the electric pig-iron furnace development at that plant. The latest one is of 4500 kw., nearly 6000 hp. The whole plant is substantially erected, and gives one the impression of being around a modern blast-furnace plant. It is smaller, but the appliances are functioning so well and the uniformity of running is such as to give one the impression that here is a commercial running plant.

At Hagfors, 100 miles west of Domnarfvet, there are five electric pig-iron furnaces, and they are working very well. I spent half a day there with Mr. Bergquist, in charge, discussing all the points of the furnace plant. They have gradually changed first one thing and then another, widening out the neck of the furnace at the lower part, improving the holders, electrodes, etc. They have electrodes up to 30 in. diameter in use, and the replacement of the arch of the furnace when it becomes damaged is now well taken care of. There are other details of operation which were being mastered in about the same way that we are used to seeing around ordinary blast-furnaces.

It seems to me the experience which has been gained by the Swedish plants is sufficient to make them practicable in a great many parts of the world, and I expect to see in the near future a considerable extension of the use of these furnaces in such countries as Canada, Italy, Brazil, Mexico, Japan, or other places where high-grade iron ore is available and there is a good supply of charcoal and cheap electric power. Electric power in Sweden is now costing more than it did before the war, because the plants are requiring increased hydro-electric installations which cost much more to install now than formerly. The era of $8 a year horsepower is past. It is now averaging more nearly $10 to $12 in the developments which are now under way.

Electric Steel

As regards electric furnace steel, I visited the largest electric steel works in Norway. These works, at Stavanger,[1] have been for some years making very fine qualities of electric steel, melting down steel scrap in an open-hearth furnace and then refining in an induction electric furnace. Before the war they found it cheaper to do the melting in the open-hearth furnace than to do it in an electric furnace, even though power was costing them only $6 per hp.-yr. But with the increased price of coal during the war (it cost up to $80 and $90 a ton, but it is now down to $20) they have calculated that they can melt cheaper in the electric furnace than in the open-hearth furnace using coal. Therefore, that same company has put in two furnaces, one of the Frick type, and the other of the Heroult type, so that henceforth its practice will be to melt cold charges in the electric furnace instead of using its former duplex open-hearth-electric practice.

Labor Conditions

I found the labor conditions in Sweden better than in Norway, but in both countries it is much worse than here. Particularly in Norway, the labor element is extremely disquiet, especially among the younger unmarried men, between 20 and 25 years old. They go around with pipe in mouth, hat on one side, hands in pockets, and have the Bolshevist ideal of doing as little work as possible and getting impossibly high pay for it.

There also seems to be an almost entire lack of confidence and understanding between employers and employees. For instance, the employers may be trying to figure out whether they can keep the business running and make any profits, when the workmen come around with a demand for 50 per cent increase in pay and a 6-hr. day. The employers then throw their hands up and say that it isn't in it. Many of the plants operating in Norway cannot pay the demand of the laborers for wages and keep running, so that the workmen are killing their own chances for getting higher wages.

If it is said to these workmen that the industry cannot stand the high prices which they demand, they reply: "We don't believe it. They could give it to us if they wished to. It is merely greed that prevents the employers from making a profit; if they can't run it, let the government take it over."

That is the attitude of a large part of the labor element in Norway. It is certain that if private enterprise cannot operate and make a profit, then it is impossible for the government to do so.

Remedy for Labor Unrest

There seems to be a deadlock at the present time, which can only be solved in one of two ways; that is, either that the men get hungry and have to work, or that a re-establishment of confidence can be had between the employer and employee, by putting an employees' representative on the board of direction and working on the co-operative plan.

I believe that this will come. I talked with many men, some high up in governmental and industrial circles, and they seemed to think that it would be a good plan thus to have the workmen find out the actual condition of the business and the possibilities of wages, because, as one sees it now, there is absolutely no limit to the workmen's demands except the blue sky. If they demand so much and get it, they want more and more. The actual limit is necessarily imposed by the condition of the business itself. If the representative of the workmen upon the board advises the workmen that certain things are possible and others impossible, then it is hoped that the workmen may be reasonable enough not to demand what their own representative tells them is the impossible.

The near future, I think, will see this development. The cards will have to be placed on the table. The greed of some employers who want, if it is possible, to make 100 per cent off their capital in a year, and put it in their own pockets, will be blocked, and I think this will lead to a fairer distribution of the profits resulting from the co-operation of labor and capital. It seems to me that this offers the best prospect toward a re-establishment of confidence, and a return to intensive industrial operation.

Foreign Commerce of United States for 1918

In compliance with recent legislation requiring that the annual report on the foreign commerce and navigation of the United States hereafter cover the calendar instead of the fiscal year, the Bureau of Foreign and Domestic Commerce has published statistics of United States trade with foreign countries for the year ended Dec. 31, 1918. The previous report published covered the fiscal year ended June 30, 1918, so, in order to provide a continuous record, the half-year period from July 1 to Dec. 31, 1918, is shown separately. Copies of this publication may be procured from the Superintendent of Documents, Washington, D. C.

Melting Point Methods at High Temperatures—II

A Description of the Determination of Melting Points of Metals, Alloys, Salts and Refractory Materials by the Use of Thermo-Electric, Resistance and Optical Pyrometers*

By LEO I. DANA AND PAUL D. FOOTE

On account of the low heat diffusivity and latent heat of fusion of salts and silicates, considerable difficulty is encountered because of the obliquity of the melting or freezing curves. Consequently it is necessary to use tall, narrow charges and slow rates of heating. Few salts can be heated in a reducing atmosphere, and hence graphite crucibles are prohibited. Porcelain and fire clay are attacked by most salts, so that metal crucibles must be employed. Of these platinum, platinum alloys, and nickel have the widest utility. The thermocouple protecting tube of porcelain must itself be protected by a thin metal sheath. In many cases salts do not attack platinum perceptibly, so that the thermocouple may be immersed directly in the molten salt. When this is done, the crucible must be free from volatile metals such as iridium, especially for work at high temperatures; otherwise the couple will become contaminated. If no protecting tube is employed, very small crucibles may be used, from 1 to 2 cm. in diameter and 2 to 4 cm. high. If the salt is quite volatile and the vapors distill into the furnace, an additional protection tube for the furnace heater is necessary. The melting or freezing points of the nitrates, chlorides and sulphates of the alkali and alkali earth metals may be determined as above.

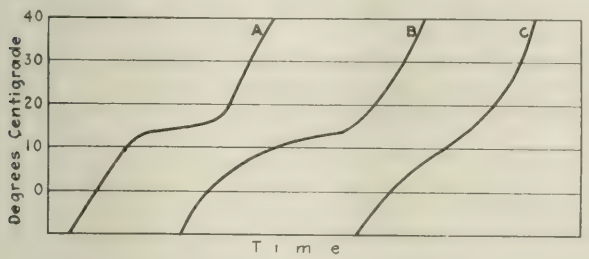

FIG. 12. SILICATE MELTING CURVES

The melting points of silicates and other compounds of metallic oxides are usually comparatively high, and their great viscosity when liquid, their slow melting, slow crystallization, and undercooling introduce many difficulties in the melting point determination. Many crystalline silicates which have a definite melting point do not show a definite freezing point on account of the high viscosity of the liquid, thus preventing the formation of crystal nuclei. The liquid supercools and the viscosity may so increase that a glass is formed; thus borax may be melted but once, and on cooling a clear glass results which with reheating shows no marked heat transformation at the melting point. Other materials acting in this manner to a lesser degree are diopside, $MgSiO_3.CaSiO_3$, melting at 1391 deg. C., and lithium metasilicate, Li_2SiO_3, melting at 1202 deg. C. Consequently in silicate melting point determinations the melting curves are almost exclusively considered. In Fig. 12 *A* represents about as good a curve as is usually obtained with a silicate.

In another class of silicates the melting requires a large time interval, probably on account of the high viscosity of the liquid, so that the material will easily superheat as well as supercool. Both the melting and freezing curves may be so oblique that no halt in the curves is perceptible. In Fig. 12 *C* shows a heating curve for a slow melting silicate, which gives practically no information as to the true melting point. Silicates of this class may be differentiated by studying the melting curves obtained for different rates of heating. If the faint trace of a halt in the melting curve shifts with rate of heating, it is fairly conclusive evidence that this method is not applicable. A method which has been employed for such materials by the Geophysical Laboratory is to heat the substance for a considerable time at various constant temperatures and after quenching in mercury, investigate the crystalline properties under a petrographic microscope. The crystalline structure is destroyed by the melting. Materials of this type are albite, $NaAlSi_3O_8$, melting below 1200 deg. C., orthoclase, $KAlSi_3O_8$, and quartz, SiO_2, melting at 1710 deg. C.

FIG. 13. Silicate Melting Point Apparatus

The apparatus used by the Geophysical Laboratory for silicate work is shown in Fig. 13. The marquardt or sillimanite porcelain tube *A* is jointed to a platinum sleeve *B*, 5 x 1.2 cm., into which tightly fits the platinum crucible containing the charge. The platinum thermocouple, carefully centered, is inserted with no protection. Great care must be taken to avoid the presence of impurities such as chips of porcelain from the tube *A*, etc., as the lowering of the freezing point by impurities is proportional to the square of the absolute temperature and becomes very serious at high temperatures. In Fig. 12 *B* shows a heating curve of a silicate containing an impurity.

White has found that in general the electrical leakage through the molten salt is not of serious importance. However, this must be considered for precision work at high temperatures, as well as the leakage from the furnace heating current to the couple. The latter may be diminished by preventing any part of the heated couple or crucible from coming into contact with the furnace wall. Thermionic leakage to the couple may be minimized by electrostatic shielding.

*Part I was published in CHEM. & MET. ENG., Vol. 22, No. 1, pp. 23-28, Jan. 7, 1920.

Leakage may usually be detected by moving the couple, and by reversing or cutting off temporarily the heating current.

The rate of heating should be from 2 to 8 deg. C. per minute. On account of the tendency of the melting curves to obliquity and on account of the small heat transformations involved, it is necessary to maintain a careful furnace control so that irregularities in heating will not appear on the melting curve. Even then it is possible that more sensitive methods of thermal analysis may be desirable, such as the inverse rate or the differential methods described elsewhere.[7]

Platinum-Wound Furnace

Since an oxidizing atmosphere is necessary, the furnace employed for high melting point work with salts and silicates must be wound with platinum. Fig. 14 shows a furnace suitable for temperatures up to 1550 deg. C. The tube *A*, of Norton alundum R. A. 98, 33 cm. long, 3 cm. bore, and 3 mm. wall, is wound with platinum or platinum-rhodium ribbon *B*, 1 to 2 cm. wide and 0.01 or 0.02 cm. thick with the turns about 3 mm. apart. The ends of the foil are bound with a turn of

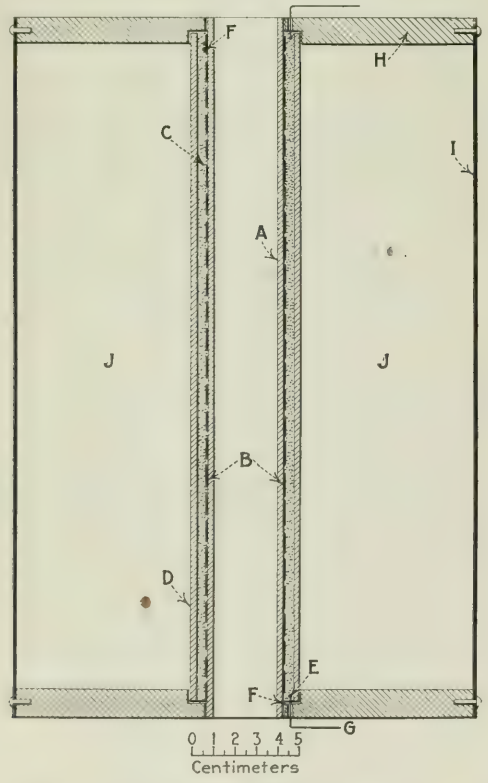

FIG. 14. PLATINUM-WOUND MELTING POINT FURNACE FOR SILICATES AND METALS

platinum wire *F*, to which are fused the heavy silver lead wires *G*. Around the tube *A* is a second tube *D*, and the space between the two tubes is packed with Norton R. R. alundum 120 mesh to prevent local heating of the ribbon. The space between the shell *I* and the tube *D* is filled with sintered magnesite.

Table of Melting Points. Table III gives the melting points of several salts and silicates determined at the Geophysical Laboratory.

Technical Melting Point Determinations. For ordinary technical testing in which an accuracy of 5 to 10 deg. C. is sufficient the general procedure is the same as that discussed for precision work except that less care is required in experimental details. When large couples are used it is necessary to procure much larger crucibles, approximately in the same proportion illustrated by Table I.† It is not a wise practice to immerse a bare base metal couple directly in a molten salt or

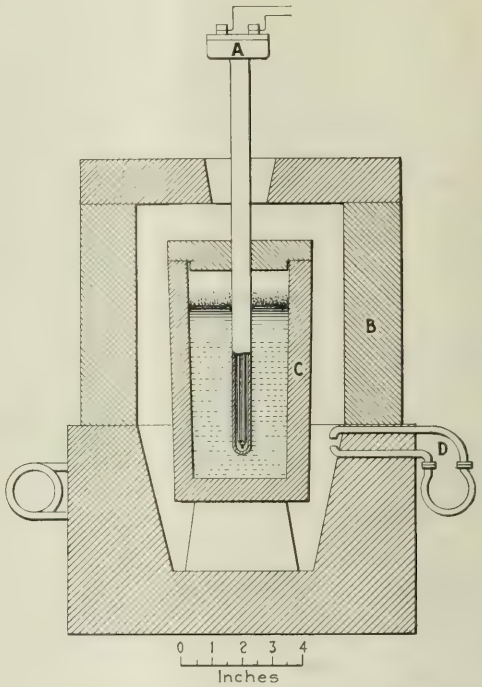

FIG. 15. GAS FURNACE FOR TECHNICAL MELTING POINTS

metal. The couple should be protected by a metal or ceramic tube, preferably of thin wall in order to reduce heat conduction. For metals, Dixon graphite crucibles, which are less susceptible to oxidation than the Acheson graphite, or pure fire clay (except for aluminum) are satisfactory, while for salts iron, calorized iron, nickel nickel-chromium alloys or Duriron are serviceable. For

TABLE III. MELTING POINTS OF SALTS, SILICATES AND OTHER COMPOUNDS

Substance	Formula		Melting Point Deg. C.

Calcium aluminate	$CaO.\ Al_2O_3$		1592
Cristobalite	SiO_2		1710

the checking of thermocouples, pots of commercial tin, lead, zinc, sodium chloride and copper of a fair degree of purity are sufficient. The melting points of these materials will rarely differ from those of the pure substances by 10 deg. C., and if close checks are required the melting points may be determined by means of an accurately calibrated couple. A gas furnace may be employed for heating, but the flame should not be allowed

[7] For further details on silicates see publications of the Geophysical Laboratory in the *Am. J. Sci.*, and Jaeger, "Physico-chemical Measurements at High Temperatures," Walters, Groningen, Holland, 1913.

† See CHEM. & MET. ENG., vol. 22, No. 1, p. 24.

to strike the crucible on one side only. If the burner is directed along a radius of the furnace instead of tangential to its surface, a baffle may be interposed before the crucible or the crucible may be mounted on a pedestal above the flame. Under these circumstances it is desirable to protect the crucible by an outer metal tube. An excellent form of gas furnace is the melter's furnace made by the American Gas Furnace Co. and illustrated by Fig. 15. For ordinary laboratory work size No. 3 is suitable. The furnace is provided with three burners *D*, only one of which appears in the drawing, mounted tangentially to the circumference in order to produce a spiralling flame. Excellent temperature uniformity is thus obtained.

Wire Method. The wire method of determining melting points of metals consists in inserting at the hot junction of the couple a small length of wire drawn from the material to be investigated. Usually a rare metal couple is employed. The couple is cut apart at the hot junction and the sample wire, preferably of about the same diameter as the wire of the couple and about 1 cm. or less in length, is fused (not soldered) in. The couple is then mounted in a narrow tube, which may be closed at the lower end, and inserted into a uniformly heated furnace as illustrated by Fig. 16. The temperature of the furnace is increased very slowly as the melting point is approached and the emf. of the couple is observed at the instant that the circuit is broken by the melting, evidence of which is shown by the galvanometer deflection of the potentiometer or of the simple indicator dropping to zero. The temperature corresponding to this emf. on the calibration curve of the couple is the desired melting point. The introduction of the short pieec of metal produces no effect on the thermo-electric circuit, provided it is at a uniform temperature. The two metals most satisfactorily employed with this method are gold and palladium, although many other metals could be used with the proper atmosphere. The experimental manipulation for palladium is a little difficult. A platinum-wound furnace similar to Fig. 14 must be used, and the two insulating tubes of the couple must not come into contact with each other or with the furnace walls; otherwise electrical leakage occurs. A leak between the wires of the couple produces a peculiar effect at the instant of melting of the palladium. Instead of the galvanometer showing zero deflection it will indicate the very large voltaic emf. developed when the porcelain acts as an electrolyte, since the metallic shunt of low resistance across this emf. is broken when the palladium melts. With proper care, results by this method are reproducible to 1 deg. C. It is frequently convenient to sight a microscope of low power on the loop of wire and observe the melting. If the rate of heating is slow, sufficient time elapses from the incipient melting to secure several reliable potentiometric readings before the circuit is broken.

FIG. 16. APPARATUS FOR WIRE METHOD

The wire method is occasionally employed for copper heated in air. The temperature so obtained, however, is not reliable. It may be any value from 1063 to 1083 deg. C., depending upon the rate of heating and hence upon the amount of oxide formed.

II. Use of Resistance Thermometers

The standard temperature scale as used and distributed by the Bureau of Standards is defined in the interval —40 to 450 deg. C. by means of platinum resistance thermometers calibrated in ice, and steam and sulphur vapor (444.6 deg. C.). Platinum of a high degree of purity is readily obtainable, and its purity is assured if the mean temperature coefficient of resistance of the thermometer between 0 and 100 deg. C. is not less than 0.00388 and if the constant δ of the Callendar equation used for expressing the relation between temperature and resistance is not greater than 1.52. The temperature scale from 450 to 1100 deg. C. is defined by the melting points of pure antimony, silver, gold and copper and interpolation between these points is based on the temperature scale defined by the rare metal couple (Pt-90 per cent Pt, 10 per cent Rh) calibrated at two of these fixed points, antimony and copper, and a third point, zinc, fixed by the resistance thermometer.

Advantages of Resistance Thermometers

It has been found that the scale defined by the resistance thermometer calibrated as above agrees with the thermocouple scale as closely as this may be reproduced, even up to 800 deg. C. Above this range the behavior of a resistance thermometer is likely to be erratic. The calibration is subject to changes on account of volatilization of the platinum and strains introduced by the warping of the mica frame upon which the wire is wound. Reliable precise measurements can be obtained only by inter-comparison of several thermometers. Below 800 deg. C., however, the temperature scale defined by the resistance thermometer is probably more closely reproduced by different resistance thermometers than is the thermocouple scale reproduced by different thermocouples. Hence when very high precision is required, 0.1 deg. C. or better, the resistance thermometer offers some advantages in the range 450 to 800 deg. C. Below 450 deg. C. the resistance thermometer is the most accurate means of temperature measurements, since its temperature scale is accepted as standard. In melting point work of the highest precision from 450 to 800 deg. C. there is some question as to whether the error resulting in a temperature gradient over the entire bulb of a resistance thermometer introduces as large an error as may arise with a thermocouple, which requires a much smaller region of temperature uniformity, for example the errors due to inhomogeneity of the wires of the couple.

The general technique to be observed in melting point determinations with the resistance thermometer is the same as that required in thermocouple work of the highest precision. The large size of crucible described in Table I is necessary since the bulb of the thermometer is from 5 to 8 cm. long. The most extensive paper on the application of resistance thermometers to melting point determinations is by Waidner and Burgess.[8] This paper contains a complete bibliography up to 1909. Later developments have been made only in the methods of measurement, such as bridges, etc., and are described by Waidner, Dickinson, Mueller and Harper and by Mueller.[9]

[8] Waidner and Burgess, Bu. of Standards, Scientific Paper No. 124.

[9] Waidner, Dickinson, Mueller and Harper, "A Wheatstone Bridge for Resistance Thermometry, Bu. of Standards, Scientific Paper No. 241. Mueller, "Wheatstone Bridges and Some Accessory Apparatus for Resistance Thermometry, Bu. of Standards, Scientific Paper No. 288.

III. Use of Optical Pyrometers

Metals and Alloys

Above 1400 deg. C. the difficulties involved in the use of thermocouples for melting point determinations are very great. Refractory tubes are attacked by the metals and are permeable to gases which contaminate the couple. The calibration of the couple changes, inhomogeneity develops and troubles arise from electrical leakage. For these reasons the use of optical pyrometers is desirable, and, above 1550 deg. C., necessary. The disappearing filament type of optical pyrometer is most satisfactory, since it is capable of high precision and requires a very small source upon which to sight. Special care must be given in the use of optical pyrometers to insure that black body conditions are closely approximated.

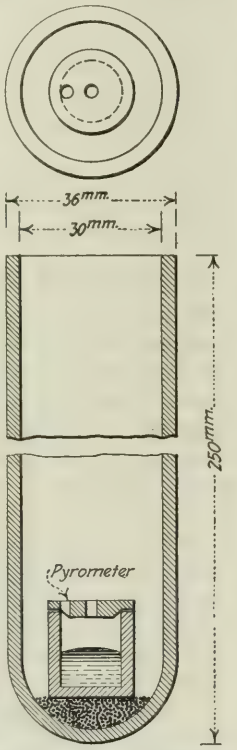

FIG. 17. APPARATUS FOR MELTING POINTS OF METALS AND ALLOYS WITH OPTICAL PYROMETER

For metals and alloys melting below 1750 deg. C. the experimental device shown in Fig. 17 is suitable. The outer tube is made of sillimanite porcelain, melting at 1810 deg. C., and constitutes the unit to be inserted into a furnace. The crucible inside this tube is about 18 mm. in diameter and 20 mm. high, and is provided with a cover having two holes, 2 to 3 mm. in diameter, in the positions illustrated. The pyrometer is focused on the outer hole, and the central hole is for observing the progress of a freezing or melting. If the metal in the crucible is molten, the central hole appears quite dark against a brighter background because the level metal surface reflects the image of the upper and cold part of the furnace. The surface under the side hole, however, is convex on account of the surface tension of the metal, and the V-shaped depression formed between the metal and the side wall affords a satisfactory black body upon which to sight the pyrometer. The outer tube should be uniformly heated for a distance at least twice its diameter, and the short crucible should be filled about half full with metal. Tall crucibles are not desirable, as they are less likely to be uniformly heated and any non-uniformity disturbs the black-body conditions. Although it is realized that such a system is not ideal for producing black-body radiation, especially when the temperature is continually changing, as is necessary in melting point determinations, still it may be concluded on the basis of many careful observations that the error in general does not amount to more than 2 or 3 deg. C. For more precise work it is possible to fix to the cover of the crucible a re-entrant tube immersed directly in the metal, and into which the pyrometer is sighted. This method is frequently employed for the standardization of an optical pyrometer by direct melting point determinations.[10]

TABLE IV.

Metal	Melting Point	Crucible Material	Atmosphere
Silicon	1420	MgO, Al_2O_3, or mixtures	Vacuum, N_2, H_2
Nickel	1452	MgO, Al_2O_3, or mixtures	Vacuum, N_2
Cobalt	1480	MgO, Al_2O_3, or mixtures	Vacuum, N_2
Iron	1530	MgO, Al_2O_3, or mixtures	Vacuum, N_2
Palladium	1550	MgO, Al_2O_3, or mixtures	Air
Chromium	1615	MgO, Al_2O_3, or mixtures	Vacuum, N_2
Platinum	1755	MgO, Al_2O_3, or mixtures	Air

Table of Melting Points. Table IV gives the melting points of several pure metals which with their alloys may be investigated by the above method.

Crucibles. Crucibles containing either graphite or silica must never be used for precision work with these metals and their alloys. Silica-free crucibles are not sold by the porcelain manufacturers, but can be made in the laboratory without much difficulty from magnesia, alumina, or mixtures of the two. Pure magnesia aluminate does not begin to melt below 1925 deg. C., and hence is sufficiently refractory for the above metals. Pure fused alumina and pure fused magnesia made by the Norton Co. are ground to 150 to 200 mesh and mixed in the approximate proportion 75 per cent alumina and 25 per cent magnesia (the exact proportion is immaterial). The powder is slightly moistened and compressed in a briquetting mold similar to that illustrated by Fig. 18 into a cylinder having the outside diameter of the crucible. This cylinder is fired in a graphite crucible at a temperature of 1700 deg. C. for a few moments. The Arsem furnace described later, or any carbon resistor furnace having a clean atmosphere and capable of maintaining this temperature, is satisfactory.

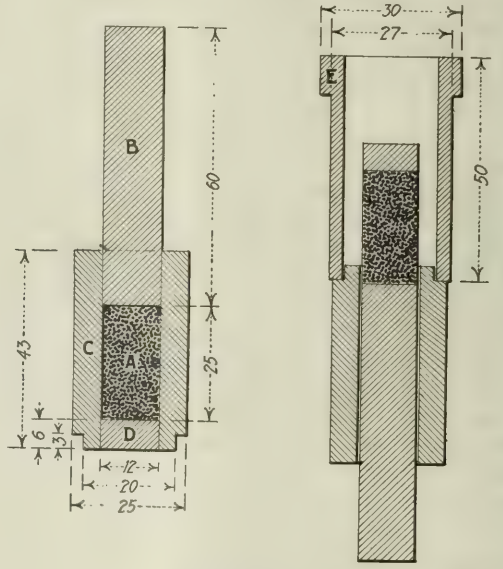

FIG. 18. BRIQUETTING MOLD FOR REFRACTORY MATERIALS

The cylinder sinters to a hardness sufficiently strong to be handled, and with care it is possible to drill out a hole large enough for the metal, with an ordinary twist drill. The crucible is then refired at a temperature between 1800 and 1900 deg. C. A cover is readily made.

For ordinary testing with metals other than palladium and platinum, the sillimanite crucible ("impervite" or "usalite") may be employed. These are of course attacked and must be discarded after each determination, but experiments indicate that the impurity introduced in the metal by a single heating affects the melting point less than 10 deg. C. Such crucibles are useful for ordinary work with steels and nickel-chromium alloys.

Furnaces. None of the metals or alloys of high melting point, except the rare metals, can be melted in air

[10] Kanolt, Bu. of Standards, Technical Paper No. 10. Foote, Met. & Chem. Eng., vol. 11, p. 97; 1913.

vithout serious oxidation. The use of a vacuum furnace, the residual gases being CO and N_2, is satisfactory except for palladium and platinum. Fig. 19 illustrates such a furnace designed by Arsem.[11] It is readily and accurately controllable and a clear atmosphere is assured. The graphite spiral *C* is mounted in water-cooled copper electrodes. *F* is a radiation shield of graphite filled with magnesia. The pyrometer is sighted through the glass window *D* into the sillimanite tube *B* (see also Fig. 17), which is suspended from the top of the furnace. In the place of *A* the crucible shown in Fig. 17 is mounted on a bed of alundum. The porcelain tube is fairly impermeable to the hot gases and carbon vapor. With the first heating in a vacuum furnace the liquid metal usually sputters on account of evolution of gases, and may throw off the cover of the crucible, but after the first melting satisfactory readings can be taken. Suitable rates of heating or cooling near the melting point are from 10 to 20 deg. C. per minute. In this range, temperature measurements should be made very frequently, every 10 seconds if possible. Fig. 20 illustrates typical freezing curves for pure iron and chrome steel by this method.

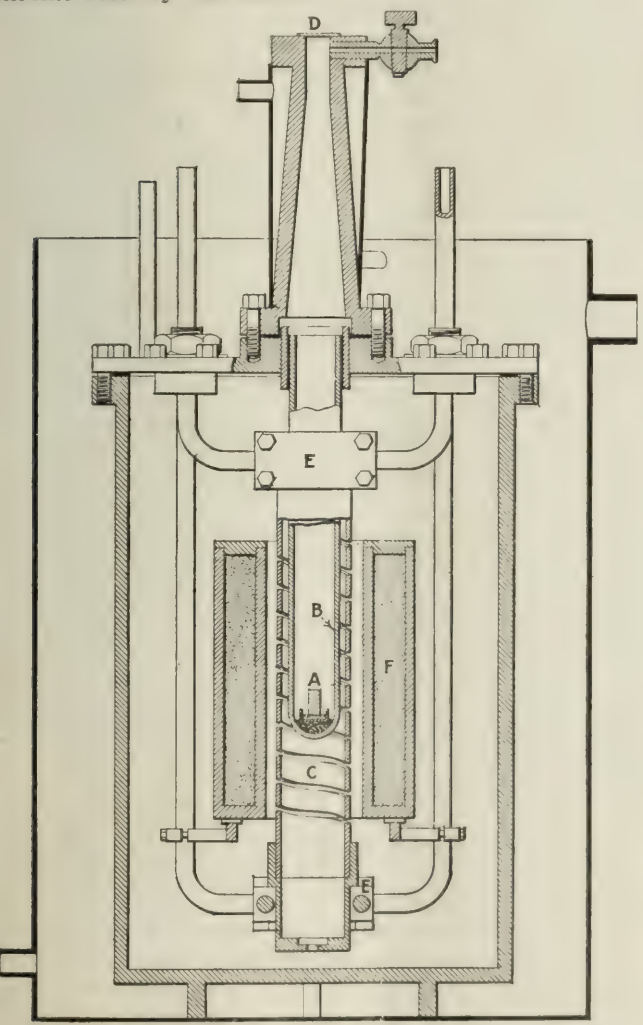

FIG. 19. ARSEM GRAPHITE RESISTANCE VACUUM FURNACE

For temperatures below 1550 deg. C. the sillimanite tube of Fig. 17 may be heated in a platinum-wound furnace if desired. The proper atmosphere for the metal can be obtained by fitting the sillimanite tube with a

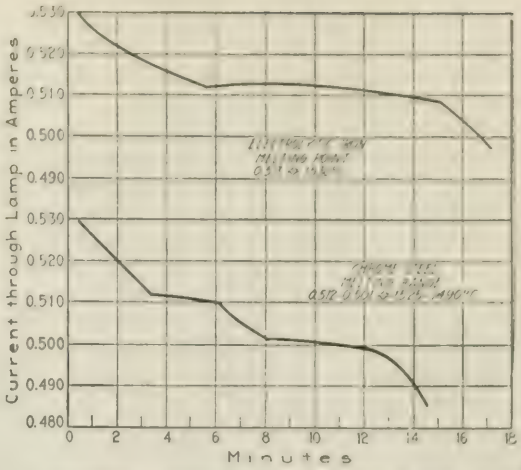

FIG. 20. FREEZING CURVES OF ELECTROLYTIC IRON AND CHROME STEEL

metal top containing a window and two side tubes through which N_2 is drawn. Another method is to insert a long porcelain tube through the furnace, in the center of which is mounted the crucible. Gas is led in at the top of this tube and out at the bottom.

Crucible melts of palladium and platinum are seldom made. Both of these metals must be melted in an oxidizing atmosphere, since in a reducing atmosphere the slightest trace of silica, which is present in nearly every type of furnace, is disastrous. Palladium may be heated in a lime, alumina, magnesia, or magnesia aluminate crucible in a platinum-wound furnace. Platinum could be melted in a furnace wound with a platinum-rhodium alloy, but the method has never been attempted. In several cases a furnace consisting of an iridium tube in which the tube serves as the resistor element has been used. The method is open to serious objections, however, on account of the rapid volatilization of iridium even when the material is coated with a protective paint such as a refractory earth mixture.[12]

Other Methods. For metals melting much above the range of platinum a modification of the wire method may be used. The material in the form of wire or ribbon is mounted as a filament of an electric lamp and is gradually heated electrically until it melts. The apparent or brightness temperature is measured by an optical pyrometer at the instant of melting. In order to correct the observed temperature to true temperature the value of the emissivity of the material must be known. This involves a separate and difficult experiment. In some cases the material in sheet form is folded into a wedge and electrically heated, and the pyrometer is sighted into the opening of the wedge, the radiation from which is approximately black. Various other methods are employed, such as sighting on a bead of the molten metal in an electric arc, extrapolation of the temperature-current curve for a lamp filament, etc.[13]

Micropyrometer. In order to determine the melting points of microscopic samples of materials Joly devised the meldometer. This consists of an electrically heated platinum strip the linear expansion of which is a measure of its temperature. The relation between elonga-

[12]Waidner and Burgess, Bu. of Standards, Scientific Paper No. 55.

[13]Waidner and Burgess, Bu. of Standards, Scientific Papers Nos. 40, 55. *J. d. Phys.*, vol. 6, p. 830, 1907. Forsythe, *Astrophys. J.*, vol. 12, p. 361; 1911. Mendenhall and Ingersoll, *Phys. R.*, vol. 25, p. 1; 1907. Pirani and Meyer, *Verh. d. Phys. Ges.*, vol. 14, p. 126; 1912. Wartenberg, *Verh. d. Phys. Ges.*, vol. 12, p. 120; 1909. Langmuir, *Phys. R.*, vol. 6, p. 152; 1915. Worthing, *Phys. R.*, vol. 10, p. 377; 1917.

tion and temperature is determined by placing samples of pure materials on the strip and observing the melting point through a microscope while the elongation is measured by a vernier screw adjustment. A more satisfactory method is by use of the Burgess[14] micropyrometer, which operates on the same principle as the disappearing filament pyrometer except that the lamp is mounted in a microscope instead of a telescope. (See Fig. 21.) This is sighted on a platinum strip, and on the strip in the field of view is placed a sample of the material to be melted, usually from 0.1 to 0.001 mg. in weight. The strip is enclosed in a water-cooled container having a clear glass window, and a reducing or neutral atmosphere is maintained. The temperature of the platinum strip is measured at the instant of melting, which is indicated with unmistakable evidence, since the material either gathers into a ball or spreads out on the strip. The pyrometer is calibrated by employing metals of known melting points. A natural question which arises is whether the sample actually takes up the temperature of the strip. If the sample were heated by radiation alone, since it receives radiation from a solid angle 2π and radiates through a solid angle 4π, it can be shown on the basis of the Stefan-Boltzmann law that the absolute temperature of the

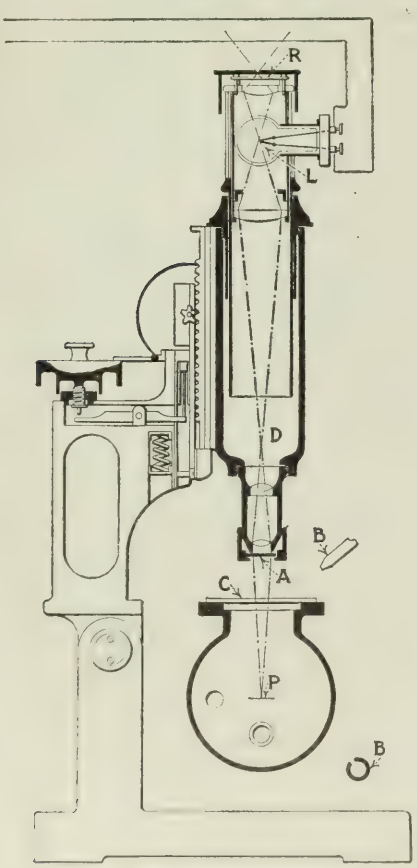

FIG. 21. MICROPYROMETER

sample would be roughly only 0.8 that of the strip. On the other hand, the microscopic sample acts as a shunt on the platinum strip and more heat is developed at this point, tending to increase the temperature. Thermal conduction along the strip reduces this effect. The fact that samples of different sizes appear to give the same value for the melting point indicates that these effects are very small and that the sample actually assumes the temperature of the strip, the heat conduction and gas convection compensating for the deficiency in the direct radiation. The method must be used with caution, however, when applied to other materials than metals, especially in a vacuum. It has been found that errors of 50 deg. or more resulted when gold was heated on a graphite strip in vacua.

Refractory Materials

Refractory Oxides. Refractory oxides are the basic constituents of minerals and of ceramic refractory materials. Their melting points are very high, and it is necessary to adopt special precautions to avoid contamination and to eliminate the smoke produced by the vaporization of the oxide. The Arsem furnace shown in Fig. 19 was used by Kanolt[15] for determining the melting points of magnesia, lime, alumina and chromium oxide. In each case heating curves by the temperature-time method were obtained with an optical pyrometer, and the results were confirmed by examination of the materials heated above and below the observed melting points. The rate of heating was about 100 deg. C. per minute near the melting point.

Table of Melting Points. Table V is a summary of Kanolt's work.

TABLE V.

Oxide	M.P. Deg. C.	Crucible Material	Atmosphere
MgO	2800	Graphite	Stream of CO and N_2 at atmospheric pressure.
CaO	2570	Tungsten, CaO	Stream of H_2 at atmospheric pressure.
Al_2O_3	2050	Tungsten, graphite	CO and N_2 vacuum; stream of CO and N_2 at atmospheric pressure.
Cr_2O_3	1990	Tungsten, graphite	CO and N_2 vacuum.

Magnesia was melted in a special form of graphite crucible, Fig. 22, which was mounted in the Arsem furnace. The pyrometer was sighted through the tube *B* on the bottom of the tube *A* immersed in the magnesia. CO and N_2 at atmospheric pressure were passed through *BCD*, thus clearing the field of view from smoke. Lime was melted in a similar container except that the parts in contact with the lime were made of tungsten. Fig. 23 shows another method employed for lime. The tube *O* compressed from pure lime was suspended in the furnace and a stream of hydrogen was passed in at *P* and out at *Q* to avoid the presence of smoke. Alumina was melted in vacuo in the same form of crucible used for magnesia and also in a graphite crucible shown by Fig. 24. This latter method with crucibles of both graphite and tungsten was employed for chromium oxide.

Firebricks and Ceramic Materials[16]

Refractory materials such as firebricks, fire clays and minerals are composed of compounds of the refractory metallic oxides, solid solutions of the oxides, pure oxides, and mixtures of these classes, together with a variety of chemical compounds. The oxides silica and alumina occur most commonly in refractory materials, and frequently in combination with these are the oxides of the alkali earth, the alkali, the iron group and the rare earth metals.

Meaning of the Melting Point. In the case of refractory materials which are either amorphous or heterogeneous mixtures of oxides and other substances there is no definite melting point. The change from the solid

[15]Kanolt, *loc. cit.*

[16]For a more detailed discussion, see L. I. Dana, Bull., A. I. M. E., September, 1919.

state to one in which the material will flow is gradual over both a temperature and time interval. In addition, physical and chemical reactions which are not equilibrium reactions often take place during melting. These phenomena practically prohibit the use of melting curves, and for ordinary technical purposes the criterion of marked flow, although indefinite from the pure scientific standpoint, is adopted. Accordingly, the practical definition of the melting point of a refractory material is that temperature at which under specified conditions a marked and distinct flow of the material begins. In terms of the deformation of a cone or cylinder the melting point is midway between the temperature at which the deformation begins and the temperature at which the material fuses into a lump or ball, or is completely bent over. The softening or fusing point of a refractory should be defined in the same manner, making the three terms synonymous. If the refractory is a pure crystalline compound it possesses a true melting point, but often, as for example with quartz and albite, the change of state takes place so slowly at the melting point that the substance may be superheated. Thus with quartz the viscosity is so high that a marked flow is not perceptible until the material is superheated by 40 or 50 deg. C.[17] For technical testing the criterion of marked flow is usually taken to define the so-called melting point even for pure crystalline compounds, and thus on the basis of such a definition the melting point of quartz is about 1750 deg. C.

Conditions Affecting Observed Values of the Melting Point. The results obtained on the basis of the above definition of melting point are influenced by a number of experimental factors as follows:

(*a*) Chemical composition.

(*b*) Size of the particles, and size, shape and orientation of the sample.

(*c*) Time and rate of heating.

(*d*) Pressure and chemical nature of atmosphere.

The relations between these factors are so complex that in most cases it is not possible to predict the magnitude or sign of the change in melting due to a variation in one or more of the above conditions. It must be noted that the melting point in actual use of the refractory material may differ considerably from that observed in the laboratory on account of the fact that the conditions of test in the laboratory are not reproduced. Thus contamination of the refractory by molten metals, slags, flue dust, etc., may alter the melting point because of the chemical reaction; also the time and rate of heating may be different. Under load the softening or melting point of a refractory is lowered on account of plastic flow. For this and other reasons the value of the melting point determined in the laboratory is not the only factor, as far as failure is concerned, to be considered in the choice of a refractory for an industrial installation.

Procedure to Determine Melting Point

Sampling, Grinding and Molding. Firebrick and other refractories of non-uniform texture and composition or with particles larger than 30 mesh should be carefully sampled. It is accordingly necessary to grind the material and mold the powder into the form of a cylinder or cone. If the refractory is of fine and uniform texture, however, a piece may be chipped off and shaped to the proper form. Fine refractory powder may be briquetted directly. Since the size of the particles may affect the melting point, the degree of fineness should be specified, at least approximately. For a large variety of substances grinding to pass an 80-mesh screen has proved satisfactory. The material is then slightly moistened and compressed into a cylinder about 2.5 cm. high and 1.2 cm. in diameter by means of the brass or polished steel mold shown in Fig. 18. In this

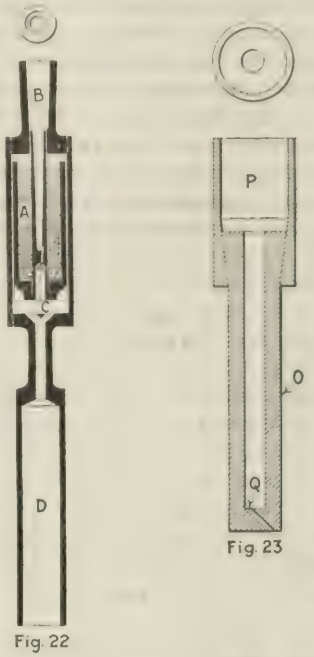

Fig. 22

figure *C* is a cylinder, *B* the piston, *D* a plug and *A* the powder. In order to remove the compressed cylinder the mold is inverted, the cylinder *E* is placed on top and the sample is slowly pushed out.

Time and Rate of Heating. The rate of heating from room temperature to about 1000 deg. C. for substances melting above 1500 deg. C. may be very rapid. A satisfactory total time of heating is from thirty minutes to two hours with a rate of from 5 to 10 deg. C. per minute from about 50 deg. below the melting point and during melting. Since the observed melting point depends to some extent upon the rate of heating, it is necessary to specify the temperature-time curve in order that results be reproducible. The following table illustrates the manner in which this may be done with sufficient exactness:

Temperature Interval	Time in Minutes
Room temperature to 1000 deg. C.	20
1000 to 1650 deg.	25
1650 to 1700 deg. M.P.	5

Type of Furnace and Conditions Existing Therein. A furnace for melting refractories should be capable of easily maintaining a temperature of 1800 deg. C., and means must be provided for close temperature regulation. The atmosphere within the furnace must not react appreciably with the specimen; otherwise the material must be protected. Graphite or carbon tube and spiral resistance furnaces operated in air oxidize rapidly, but may be somewhat protected by passing a neutral or reducing gas through them. The gas may

[17] Quartz begins to flow at 1750 deg. C. (Kanolt, Bu. of Standards, Technical Paper No. 10), while its true melting point is 1710 deg. C. (Ferguson and Merwin, *Am. J. Sci.*, vol. 46, p. 1; 1918.

also serve the purpose of carrying away smoke so that accurate optical temperature measurements may be made. Crushed carbon, graphite, kryptol, or carbon plate resistor furnaces do not permit of very precise regulation. Some forms of furnaces are so constructed that it is difficult to use an optical pyrometer. The vacuum furnace of the Arsem type, although requiring greater accessory apparatus, is more desirable on account of its freedom from smoke and because good control is possible at extreme temperatures, even at 2500 deg. C. Furthermore, the atmosphere can be made much less reducing than that in an ordinary graphite furnace. Many refractories are seriously attacked in a carbon and carbon monoxide reducing atmosphere and it is usually not possible to judge by simple inspection of the melted sample whether or not the reduction is appreciable. In many cases the surface of the specimen is attacked and a shell of higher melting point is formed, so that while the inner uncontaminated material may have been melted there is no outward evidence of this fact. In general the sample should be protected from the reducing atmosphere by a refractory tube of low porosity. In the Arsem furnace the sample *A*, Fig. 19, is protected by the sillimanite tube *B*. For temperatures beyond 1800 deg. C. no suitable protection tubes have been made. In certain special cases it may be desirable, if possible, to determine the melting point of a refractory under the atmospheric conditions to which it is subjected in actual use. Indirectly the pressure of the atmosphere may affect the melting point. For example, in a vacuum the more volatile and fusible substances, such as alkalis, may distill and thus cause a rise of melting point.

There appear to be some possibilties in the development of gas furnaces for high melting point determinations. With a suitable construction and air pressure of 10 lb. and more, temperatures of 1650 deg. C. may be maintained with illuminating gas and 1800 deg. C. with natural gas. By recuperating the waste heat or by preheating the gases the above temperature limits may be increased. It should be pointed out that for reliable melting point work it is necessary to maintain a high temperature not on a restricted small surface but throughout a considerable volume.

Temperature Measurements. Pyrometric cones have been employed as a rough measurement of the melting temperature of refractories. The refractory is thus said to have a softening point corresponding to a certain cone number. Seger and similar cones serve a useful purpose under slow rates of heating in measuring heat effects during the firing of ceramic products, but in the laboratory, when the rates of heating are comparatively rapid and may vary considerably, the determination of the cone softening point is not of much significance. For it has been repeatedly shown by numerous investigators[18] that the softening point of Seger cones depends upon the nature of the atmosphere and especially upon the time and rate of heating. Usually the more rapid the rate of heating the higher the softening temperature, variations of 50 deg. C. being easily obtained. In order that the indications by a Seger cone possess reliability it is necessary to specify the atmosphere and the time-temperature curve in the manner illustrated above for refractories. Thus in the ordinary use of Seger cones a variable factor is introduced in the temperature scale defined by the cone numbers which may have no relation to the properties and characteristics of the refractory being tested. Hence it is essential to use a strictly fixed and reproducible temperature scale. This is best accomplished by means of the disappearing filament type of optical pyrometer.

A very slight departure from black-body conditions enables one to discuss the specimen and to watch the progress of melting. It is important to keep the eye fixed on the sample in order that the melting may be observed with certainty. Sintering and vitrification take place on heating, sometimes producing shrinkage and bending; this must not be confused with the change in shape on melting. As in the case of metals, the pyrometer should be focused on a surface of the sample oblique to the line of sight, but it must be assured this surface is not reflecting light from a hotter section of the furnace, thus causing too high a reading. After the determination the sample is removed from the furnace, broken apart and inspected. The inside surface should appear homogeneous and amorphous or glassy. When the sample has been melted in a vacuum furnace a cellular structure is usually apparent, due to gases evolved during melting.

Softening Temperature of Coal Ash. The clinkering of coal ash is closely related to its softening temperature. Consequently the determination of this temperature is of considerable practical importance. The Bureau of Mines has made a complete investigation of the factors and conditions affecting the fusibility of coal ash.[19]

TABLE VI. MELTING POINTS OF COMMON REFRACTORY MATERIALS

Material	Temperature, Deg. C.
Fire Bricks:	
Fire clay	1500–1750
Silica	1700–1750
Magnesia	2150
Bauxite	1600–1800
Chromite	2050
Clays and Sands:	
Kaolin, $Al_2O_3 . 2SiO_2 . 2H_2O$	1740
Fire clays	1400–1740
Bauxite clay	1800
Bauxite, $Al_2O(OH)_4$	1820
Chromite, $FeO . Cr_2O_3$	2180
Silica	1750
Silica sands	1700–1750
Miscellaneous:	
Coal ash	1100–1500
Alundum cements	1750–2000

The following procedure is recommended. After thoroughly roasting the coal, the ash is ground to 200 mesh and roasted again in a current of oxygen. Using a 10 per cent dextrine solution as a binder, small triangular pyramids, 20 mm. high and 6 mm. wide at the base, are made from the powdered ash. These are placed vertically in a muffle or crucible.

A yellow flame burning at least 15 cm. above the cover is maintained, and the rate of heating before and during softening should be from 5 to 10 deg. C. per minute. The softening temperature is the point at which the cone fuses down to a lump or ball.

Table of Melting Points of Refractory Materials. The melting points in Table VI were determined at the Bureau of Standards principally by Kanolt, under conditions approximating those described in the section on refractory material. With the exception of pure kaolin and silica, different samples of the same general type of material may have melting points considerably different from the values tabulated.

The Eventual Retort Plant for the Distillation of Oil Shales

By Louis Simpson

IN THE Aug. 15, 1919, issue of this journal, in an article treating upon Oil Shales and upon the Scotch Dual Purpose Retort, the principles that underlie successful retorting have been discussed at length.[1] In the Jan. 7, 1920, issue the question as to where it is commercially desirable to recover the nitrogen content of these shales has been answered.[2] It seems probable that many of those interested in the exploitation of oil-yielding shales have by this time arrived at the conclusion that the Scotch dual purpose retort is not the most economical retort possible to construct and operate for the eduction of the oil gases. Yet owing to certain qualities of shale containing by-products which it is desirable to recover because of the large quantity present or from local conditions that make their recovery profitable, it is necessary to consider the construction of a plant specially adapted for the recovery of one or more of such by-products as may be found in the spent shale. For those with such a problem this article is written.

It is probably admitted by those who seek the truth and who possess an unbiased mind that the most efficient retort for generating oil gases will be one specially designed for that purpose, without having regard to the recovery of nitrogen or of any of the possible by-products. The present problem to be considered therefore is how best to recover such by-products from the spent shale, that is, from the shale as it leaves the retort after the oil gases have been driven off.

Suggestion That Two Machines Be Used

There seems to be no special reason other than that it has been a matter of convenience that the recovery of the oil gases and the recovery of the nitrogen should have been attempted on one and the same machine, even if essayed in different sections of the machine. This convenience seems to have existed in the method adopted for heating the Scotch dual purpose retort, but herein is found the great weakness of the retort.

The Scotch designers of the retort had a glimmering of the situation. They knew that the temperatures created by the combustion of the fuel used, whether solid or gaseous, were too high for the best evolution of oil gas, and so arranged to use the higher range of temperatures available for the recovery of the nitrogen, using the lower range for the eduction of the oil gases. This seemed to be a satisfactory solution of the difficulty, but in truth they placed themselves between the horns of a dilemma. If that section of the retort in which the nitrogen gases are driven off as ammonia gas was subjected to the comparatively high temperatures required, that section of the retort was soon put out of commission, and further provided a temperature far too high for satisfactory eduction of the oil gases in the other section of the retort. With such comparative high temperatures, the hydrocarbons were cracked, with the result that permanent gas was formed and the yield of oil was reduced. If, on the other hand, the temperature in the nitrogen recovery section be reduced to the safety point, so that the retort may not be burned out too quickly, then the recovery of nitrogen is very much less than the maximum possible.

Another point will be evident to the careful thinkers, viz., that the shale when it is passed to that section of the retort in which the recovery of the contained nitrogen is attempted is not in the best physical condition to give a maximum recovery, nor is it so placed, within the section, that each and every particle of the shale is submitted to the like high temperature. That disabilities exist is evidenced from the recoveries obtained, which do not exceed and usually fall under 60 per cent of the content.

Under these conditions it is surely evident that it is not possible to secure from the shale an economical extraction of the by-products, after the oil gases had been driven off, in the Scotch dual retort and that such extraction should take place in a machine especially designed for the purpose and constructed so as to withstand the necessary high temperatures.

Requirements of Machine to Extract By-Products

The requirements of such a machine would be:

1. Capability of withstanding the comparative high temperatures necessary, without breaking down.
2. Every particle of shale under treatment must be subjected to the same heat treatment.
3. The spent shale, when under treatment, should be in a very finely disintegrated condition.

To obtain economically the high temperatures necessary, to provide that every particle of the shale shall receive the like heat treatment, the method of heating the spent shale has to be radically different from that used in the Scotch retort, and seeing that, at this stage, the shale has been freed from its hydrocarbon contents, there has ceased to be any reason why the shale should not be subjected to heat, *directly applied*, instead of as in the Scotch retort, indirectly applied.

Fortunately it is not necessary to invent any new machinery to meet the requirements of the case. The horizontal revolving kiln, so long and successfully used in the manufacture of portland cement to burn the "mix" into cement clinker, which is a perfected machine, seems to be peculiarly adapted for the work to be done.

In the manufacture of portland cement the "mix" (generally a mixture of clay and lime), finely ground, is subjected to temperatures of 1550 deg. C. (2820 deg. F.) and over. In the Scotch dual retort, the shale in the nitrogen recovery section is supposed to be exposed to a temperature somewhat around 1600 deg. F., but as there must be a great variation in the temperatures next to the walls of the retort and in those found in the center of the retort, it is difficult to ascertain just what temperatures are used. It is, however, now known that to obtain the recovery of the maximum yield of nitrogen as ammonia gas, every particle of the spent shale should be exposed to a temperature of 1125 deg. C., or 2060 deg. F. It is also known that a decrease of comparatively few degrees of temperature will result in a very large and entirely disproportionate decrease in the yield, while an increase in temperature over the critical temperature increases the yield only slightly.

Horizontal Revolving Kiln to Handle Spent Shale

It will be noticed the critical temperature for the recovery of nitrogen as ammonia gas is between the temperature required for the burning of cement clinker and the temperatures now found in the nitrogen re-

[1] Chem. & Met. Eng., vol. 21, No. 4, p. 176.
[2] Chem. & Met. Eng., vol. 22, No. 1, p. 20.

covery section of the Scotch dual purpose retort. It is therefore evident that the horizontal revolving kiln, as constructed for the burning of cement clinker, will be capable of handling spent shale.

Fixed Carbon in Spent Shales

In all spent shale there remains some fixed carbon. This fixed carbon content may be as low as 2 per cent and as high as 25 per cent of the original shale. The quantity present in the spent shale will depend upon the treatment received by the shale during the process of distillation, and it must not be forgotten that during the distillation the weight of the shale is considerably reduced, the amount of reduction depending upon the richness of the shale. The percentage of fixed carbon in the spent shale will in most cases be largely increased, especially when the shale is rich.

To illustrate, certain shales upon analysis were found to contain fixed carbon in the following amounts: No. 1, 8 per cent; No. 2, 5½ per cent; No. 3, 2⅓ per cent. If through distillation no fixed carbon be lost, the spent shale would contain: No. 1, 12¾ per cent; No. 2, 8 per cent, and No. 3, only 3¼ per cent. The difference is of importance, because while it is evident that some shale may contain sufficient fixed carbon to produce, by itself, upon combustion, the temperatures required, other spent shales do not, and in such case the carbon in the shale will have to be supplemented by powdered coal, fuel oil, or gas. The question of fuel, therefore, may be in some cases the determining factor as to whether it would be profitable to recover by-products from the spent shale.

Probability of Production of Increased Quantities of Ammonia Gases

It would appear probable that spent shale burned at the correct temperature, in a horizontal revolving kiln, in the presence of low pressure superheated steam, will produce largely increased quantities of ammonia gases, and that such increase may exceed one-third of the present yields. The production will be helped by the fine crushing of the spent shale before burning, and this can be done at a low cost, because the spent shale possesses physical characteristics which will permit of its being easily crushed so that 98 per cent will pass through a 200 mesh, as is done with the "dry mix" from which portland cement is made. It should also be noted that with this preliminary crushing, and by the use of the kiln at the temperatures stated, it becomes possible to recover any potash that may be in the shale. When potash recovery is desired it may be necessary to increase the temperature, because it is stated (see page 130, R. K. Meade's "Portland Cement") that the whole of the volatile contents of the "dry mix" is "not driven off until the clinker is completely burned and about to leave the kiln," and that then less than 1 per cent remains. From this it is evident that for potash recovery a high temperature within the kiln is essential. It is fortunate that the high temperature so required will not interfere with the recovery of nitrogen.

Opportunity for Pioneer Work on Potash in Shales

It is known that potash in economic quantities has been found present in some shales, but it has not been ascertained whether its presence is universal or even if, when its presence has been discovered, it persists throughout the bed of shales in which it has been found. Much useful pioneer work might be done in this connection, now that an economical method of recovery is available.

Method for Recovery of Potash

The *modus operandi* for the complete process is as follows:

1. Eduction of oil contents of shale in retort expressly designed for that purpose.
2. Grinding of the spent shale so that 98 per cent will pass through a 200 mesh.
3. The ground spent shale is burned in a horizontal revolving kiln into which low pressure superheated steam is suitably introduced, the burning being obtained by the combustion of the contained carbon, supplemented, when required, by powdered coal, fuel oil, or fuel gas, but preferably fuel gas.
4. The fumes driven off are passed through a Cottrell dry separator, in which the dust and also certain portions of the potash are removed.
5. The fumes then pass through a specially constructed waste heat steam boiler, the product of which is low pressure steam, most of which is used in the kiln.
6. The fumes then pass to scrubbers, in which machines the remainder of the potash and the ammonia are recovered. The water from the scrubbers containing the potash and the ammonia is then treated with sulphuric acid, producing a salt which would make a very valuable chemical fertilizer.

Product Is a Concentrated Fertilizer

Though commercial mixed fertilizers are looked upon with disfavor by many, the above-mentioned mixture need not necessarily come under such strictures. As a concentrated fertilizer, in a form that is readily soluble, it would have much to commend its use.

It need hardly be pointed out that the Scotch dual purpose retort cannot provide the temperatures necessary either for a full recovery of the nitrogen or for the recovery of such potash as may be found, in commercial quantities, in some shales.

Spent Shales as Raw Material for Portland Cement

Lastly, it has been suggested that the spent shale could, in part, be used as raw material for the manufacture of portland cement. Mr. R. K. Meade in 1911 reported to the Canadian Government, page 25, Summary Report of Mines Branch of the Department of Mines, for year ending 1911: "These analyses indicate that satisfactory portland cement can be made from a combination of any one of the first three limestones and the residue from the oil-bearing shale," tested by him. Should it be desirable to produce portland cement and should the composition of the spent shale be found suitable for the production of portland cement, with or without the addition of lime to the spent shale, a comparatively small addition to the revolving kiln plant would make that part of this plant suitable for the manufacture, but it is possible, though by no means certain, that the requirements of such manufacture might be found to interfere with the recovery of the nitrogen.

In the plant as indicated there are the possibilities of great flexibility of operation. Such possibilities are entirely absent from the Scotch dual purpose retort, although, because it was a dual purpose retort, flexibility was a most important requisite.

Electric-Resistance Furnace of Large Capacity for Zinc Ores*

Details of the Experimentation Work With Electric-Resistance Furnaces of Commercial Size Based on the Author's Well-Known Plan of Making Briquets With the Zinc Ore to Be Treated and Using These Briquets as Resistors for an Electric Furnace

BY CHARLES H. FULTON†

EXPERIMENTAL work on the process was begun on a laboratory scale at Cleveland, Ohio, in 1914, and transferred to East St. Louis, Ill., in 1916, where a commercial sized furnace was in technical operation until January, 1918. The essential steps are:

Oxidized zinc ore or roasted zinc concentrate is mixed with crushed coke and coal-tar pitch and formed into briquets 9.25 in. in diameter and 21 in. long in a manner similar to that used in the manufacture of graphite or carbon electrodes, except that much less care and time are required. The composition varies with the nature of the ore. These briquets maintain their form and volume during and after the distillation of the zinc. This object is gained by using coke as the matrix and coal-tar pitch as the binder; this pitch becomes coke on heating and unites the ore particle and the original coke particle into a continuous mass. The briquet is an electrical conductor, but only to such a degree that it can be used as a resistor.

The size of the ore, as in the present practice of zinc metallurgy, ranges from fine material, such as flotation concentrate, to coarse table and fine jig concentrate. The process is not restricted to any particular kind of ore, but is applicable to pure high-grade ores, ores high in iron, and complex zinc-lead ores, since the residue from the distillation is held immovably in place within the briquet. In the case of complex zinc-lead ores, the distillation is conducted with a carefully regulated temperature so that a high percentage of lead is retained in the distilled briquet, which may then be smelted for its lead content. In present zinc smelting practice, the reduction fuel is from 40 to 50 per cent of the weight of the ore. In the briquet, it is from 60 to 85 per cent of the ore; but unless the ore is exceptionally high in residue, the distilled briquet may be used over again as coke, or as a high-ash coke for fuel purposes in power production.

SIZE OF BRIQUETS AND FURNACE CHARGE

Baked briquets are hard and tough and may be handled roughly without danger of breakage. In regular commercial work, they may be manufactured by means of extrusion on other suitable presses, after the manner in which electrodes are made, and the process be carried out continuously from the mixing to the finished briquet. The briquets weighed about 90 lb. and contained approximately 50 lb. of ore, which is about the amount in a retort charge in present zinc-smelting practice. It is proposed to make briquets 12 in. in diameter and 72 in. long, which will weigh about 600 lb. On distillation, the briquets lose from 30 to 50 per cent of their weight, but maintain their form and volume. The zinc may be completely distilled from the briquet, traces only remaining, no matter what type of ore is used. The completeness of distillation is due to the intimate mixture of ore and reducing agent maintained throughout the operation.

The second step of the process consists in making the briquet a part of an electric circuit and heating the same by an electric current to such a degree that the zinc is distilled. During this operation, the briquet is covered by a movable retort and the zinc vapor and carbon monoxide are conducted to a condenser in which the zinc is condensed. During the distillation, the briquet acts as a continuous resistor and maintains itself unaltered between the terminal electrodes. As the furnace is not limited to the interposition of one briquet between the terminal electrodes, a large number may be interposed, thus giving a large unit furnace. While direct current may be used, alternating current is preferable on account of the ease of voltage control by means of transformers. The furnace of East St. Louis held a charge of 36 briquets, arranged in twelve columns of three each, set within a circle and operated on a three-phase circuit,

*A paper read at the Chicago meeting of the American Institute of Mining and Metallurgical Engineers, Sept. 24, 1919.

†Professor of metallurgy, Case School of Applied Science, Cleveland, Ohio.

four columns in each phase, connected in the customary Y connection. The amount of charge in this furnace varied between 3100 and 3200 lb, the amount of ore being approximately 1700 lb. The time of distillation was about 6 hr.; the total time, including the placing and discharging, was 8 hr., or three charges worked off in 24 hr. The capacity of the furnace was 5100 lb. of zinc concentrate per 24 hr. A proposed larger furnace, taking nineteen briquets weighing 600 lb. each, will have a capacity of about 8.5 tons of zinc concentrate per retort per 24 hours.

Early Experimental Work

Experimental work was begun at the Case School of Applied Science, in Cleveland, in May, 1914, for the production of a zinc-ore briquet from which the zinc could be practically completely distilled, and leave the briquet of the same volume and shape as before distillation. The experiments were carried on with all sizes of briquets ranging from 1 in. in diameter and 1 in. long up to 9 in. in diameter and 20 in. long, and with spherical briquets up to 8.5 in. in diameter. Satisfactory briquets were made from practically every type of zinc-bearing material.

The "indestructible briquet" was intended for an automatic externally fired furnace,[1] but in 1915 experiments were begun using the briquet as the resistor. The first briquets were 1 in. in diameter and 1 in. long, but later the briquets were 3 in. in diameter and 4 in. long; the furnace held from 48 to 56 arranged in eight columns 6 or 7 briquets high, set up very much in the manner shown in Fig. 1 and operated in one continuous circuit. At first, direct current was used; later, alternating current. The distillation, in almost every instance, could be carried to completion, even with the many electrical contacts in the furnace, demonstrating that the indestructible briquet made a perfect resistor if properly made. On the basis of this work the East St. Louis plant was planned, not as a commercial plant, but as an experimental plant for the purpose of working out the technical details of a commercially sized furnace.

The Briquet

The briquet must form an intimate mixture of the roasted ore, reducing agent, and binder. A particle of ore should be in contact with a particle of reducing agent and both should be surrounded with a film of binder to unite all the particles into a coherent mass. In known applications of briquetting to ores, the briquet is destroyed during the operation that extracts the metal. In this particular case, the briquet must preserve its form and be practically of the same volume after the extraction of the metal as it was before in order to maintain passage of the electrical current. If the briquet should collapse during the distillation process, the furnace would become inoperative. Another advantage of the indestructible nature of the briquet, in the case of such ores as lead-zinc, zinc-copper, or franklinite, is that the residue is in the form best suited for further metallurgical treatment.

The briquets are made with an excess of the reducing agent, coke, so that after distillation there will remain sufficient matter to maintain the original volume of the briquet. In general this condition is obtained if the weight of the distilled briquet is not less than 40 to 50 per cent of the original briquet.

[1] D. B. Jones, U. S. Patent No. 1,292,330

Zinc ores and zinc-bearing materials differ widely in the nature and amount of mineral residue left after the distillation of the zinc, as shown in Table I. The nature and amount of the residue left by the ore have great influence on the stability of the briquet during and after distillation.

TABLE I. AMOUNT OF MINERAL RESIDUE IN ZINC ORE

Name of Ore	Per cent of Residue, by Weight	Character of Residue
Mascot, Tennessee	12.5	Largely silica with a little iron oxide.
Wisconsin ore, No. 1	15.8	Largely iron oxide, some silica.
Wisconsin ore, No. 2	18.3	Same as above.
Missouri ore	20.9	Largely iron oxide, some silica.
Canyon City, concentrate	27.9	Mostly iron oxide and silica.
Willemite zinc ore, from Franklin Furnace, N. J.	36.7	Mostly silica.
Franklinite zinc ore, Franklin Furnace, N. J.	55.58	Chiefly iron and manganese oxides.
Zinc dust, zinc oxide	None	

Coke Contents of Briquet

Enough coke must be added to the ore to furnish the necessary carbon for the reduction of all the reducible oxides in the ore, plus such an amount that the weight of the briquet, after distillation, will be not less than 40 to 50 per cent of the original briquet. Ores that leave a small amount of residue require more coke than ores that leave much residue. As the briquet must at all times be an electric conductor, there must always be present sufficient carbon in the coke, by which the current is chiefly carried.

The nature of the residue also is of great importance. If the residue is siliceous in character, like that of the willemite, which after distillation is in the form of comparatively sharp angular grains fused only on the edges, less coke is needed for a strong briquet than if the residue is of the nature left by franklinite, which is in the form of round fused globules. The sharp angular grains are bound into a suitable network with the coke grains, while the round fused globules must be held by the coke skeleton and in themselves give no strength to the structure they are part of. In the case of franklinite, the residue consists largely of small globules of an iron manganese alloy, which aids in the conductivity of the mass; in the case of willemite, the siliceous residue is a non-conductor.

From the standpoint of non-conductivity, a lime residue is most objectionable, as, under certain circumstances, this lime will form calcium carbide with the briquet, giving rise to high resistance. An ore containing a high lime residue will make an excellent briquet that will act normally in the furnace until a certain temperature is reached, after which, due to to the combination of lime and carbon, the resistance will increase and the briquet become locally overheated and break down. This difficulty can be overcome by an extra amount of coke. The proper amount of coke for different types of ores is, approximately, as follows:

	Per Cent of Weight of Ore
Willemite[2]	30 to 40
Franklinite	70 to 80
Pure Mascot ore	70 to 75
Canyon City ore	60 to 70
Missouri silicate ore	85
Zinc dust	70

Pitch Content of Briquet

The grains of ore and coke must be surrounded by a film of binder, which should have an appreciable thick-

[2] This proportion makes a strong briquet that will withstand distillation in an externally fired retort, but for electrical distillation the coke must be increased.

ness. As the binder must cover a certain amount of surface, the smaller the ore and coke particles the greater is the surface to be covered; therefore the amount of binder varies directly with the fineness of the ore and coke. By experiment it was found that a satisfactory briquet can be made if the amount of binder is between 10 and 15 per cent of the weight of the ore plus coke. More binder than this is detrimental, as the excess will be squeezed from the briquet during pressing; less, in most cases, will not give a satisfactory briquet. The percentages given apply to moderately fine ore, such as will pass through a 65-mesh screen, and to moderately fine coke, such as will pass through a 10-mesh screen. If the zinc-bearing material is excessively fine, as for instance zinc oxide or leaded zinc oxide, more binder must be used.

Size of Ore Particles

Within certain limits, the size of the ore has relatively little influence on the final strength of the briquet; neither has it much influence on the rate of distillation of zinc from the briquet or the completeness with which the zinc is extracted. Ore that passes through a 10-mesh screen and 86 per cent of which is coarser than a 35 screen gives practically no different result from ore all of which passes through a 200-mesh screen. Usually the material furnished the zinc smelter is comparatively fine and sometimes is very fine. Experiments with material coarser than 8-mesh have not been made. The ore or concentrate usually is made up of particles ranging in size from approximately $\frac{1}{10}$ in. down to an extremely small size. This mixture is an advantage, although good briquets can be made from very fine ore. In the case of ores that give a fused residue in the form of little pellets or globules, as for instance franklinite, the coarser ore does not give as good results as the fine ore, as the first gives opportunity for these fused globules to segregate and coalesce within the briquet. Small globules are more permanently held in place by the coke skeleton. The size of ore particles has such little influence on the ultimate stability of the briquets because the particle is practically destroyed during distillation, since it loses in the case of most zinc ores by far the greater part of its weight.

Size of Coke Particles

The size of the coke particle has a very decided influence on the strength of the briquet. Very fine coke gives a much stronger briquet than moderately fine or comparatively coarse coke. For example, a cylindrical franklinite briquet, 3 in. in diameter, 4 in. high, made with 100 parts ore, 70 parts coke, and 20 parts pitch, but in each case with different sizes of coke, had the following crushing strengths: 20-mesh, 15 lb. per sq.in.; 48-mesh, 200 lb. per sq.in.; 100-mesh, 610 lb. per sq.in. When it is desired to obtain an especially strong briquet, relatively fine coke should be used. However, as the coke increases in fineness and fine ore is used, the amount of binder will increase, which is undesirable from a commercial standpoint.

Character of Coke Used

The coke used must be firm and hard, not soft and spongy. It should have a relatively low ash content, particularly if it is used with ore containing much residue. If it is to be used with relatively pure ore, or with blue powder, the ash content may be high Good, screened coke breeze, such as gashouse breeze or by-product oven breeze, is suitable if the ash content is not too high.

Character of Pitch Used

The character of the coal-tar pitch used is all important. The chief points to be noted are the character of the coke left after the distillation of the volatile matter, the percentage of coke remaining after distillation, and the melting point of the pitch. In general, a high melting-point pitch, 170 to 200 deg. C., leaving a high percentage, 55 to 60, of good firm coke is best. Since the briquet is molded hot and is taken from the mold while warm, it is weak, and the lower the melting point of the pitch the weaker is the briquet. A briquet made with a high melting-point pitch is quite strong and stands handling when taken from the mold.

High melting-point pitches obtained by mixing rather low melting-point pitch with fine amorphous carbon will yield a high percentage of coke, but they are weak and do not give good, permanent binding properties; neither have they good initial binding properties.

Methods of Making Briquets

A number of methods may be used for making briquets. The first method used in the experimental work was to thoroughly mix the coke, ore, and pitch (in powdered form) and heat this mixture, on a large hot plate, to between 175 and 200 deg. C., or until yellow fumes appeared from the pitch. when it is granular and somewhat plastic, but not sticky. It was then molded in cylindrical steel molds, with a slight taper, the material being compressed by means of a steel plunger, the bottom of the mold being closed with a small disk to hold the material in place. The pressure varied between 500 and 1000 lb. per sq.in. For the best results the mold should have a temperature between 75 and 90 deg. C. when a high melting-point pitch is used. Under these conditions the briquet will come from the mold with a smooth exterior and sharp edges. The briquet, immediately after expulsion from the mold, is somewhat weak, but becomes strong and firm on cooling.

The second method, used for making briquets 9.25 in. in diameter by 22 in. long, employed at the East St. Louis plant, is as follows: The ore and coke in proper proportions are thoroughly mixed, slightly damp, in a knife-blade mixer and then stored in bins and fed as needed to a Bartlett-Snow kiln drier, provided with plows. Here it was heated to about 250 deg. C. and discharged into a hopper at the end of the drier, from which it was drawn into a hopper car in lots of approximately 500 lb. This hopper was picked up by the crane and discharged into the knife-blade mixer, where the proper amount of molten pitch was immediately added and the contents mixed for 3 to 5 min., after which the mixture was discharged into a small, flat, brick-lined car kept at a temperature of about 250 deg. C. This car was transferred to the tamping machine, made of a 3.25-in. Ingersoll rock drill

The tamping tool was a three-arm steel casting provided with cylindrical steel teeth 3 in. long, which were replaced when necessary. The arms of the tamping tool freely cleared the sides of the mold, which was made of heavy cast steel, in three parts longitudinally, the parts being held together, during molding, by hinged bolts fitting into slots. A specially shaped heavy steel base plate under the tamping machine insured a constant

and fixed position of the mold during tamping. The bottom of the mold was closed by a steel disk 1.5 in. thick, which was set in a circular depression 1 in. deep in the steel base plate, causing the disk to project about 1 in. below the bottom of the mold while the walls of the mold rest on the base plate. The mold was then tamped nearly full of the mixture, which at the molding place has a temperature of 160 to 175 deg. C. The mixture was fed into the mold by a long narrow scoop shovel and tamped in, the tamping

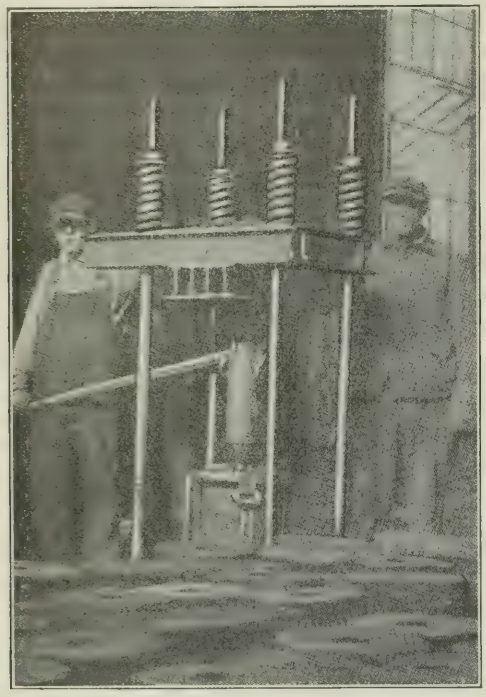

FIG. 2. BRIQUET PRESS

and feeding being simultaneous. As the mold filled, the tamping tool was raised by the feed device of the rock drill.

The mold and its contents were then transferred to the adjacent finishing press, which was made from a railroad jack and used in the inverted position (see Fig. 2). A special plate under the jack permitted the mold to be placed accurately in position. The remaining space in the mold was filled with the mixture, a top steel disk put into place, and the contents of the mold compressed until the pressure reached 1000 lb. per sq.in., the pressure being determined by the contraction of the springs of the press. The weight of the mold and its contents, as it was placed under the press, rested on the bottom disk, which projected about 1 in. below the bottom of the mold. By this means both top and bottom pressure were obtained, which is preferable to pressure being applied from the top only. After the pressing, the bolts holding the mold together were slid out of place and the parts of the mold removed from the briquet, which was then placed on a car, where it is allowed to cool and become firm.

Small briquets have also been made on a laboratory scale by the method of "cold mixing." The ore and coke are mixed with powdered pitch and then moistened with zinc-sulphate solution and pressed into briquets. A typical mix is represented by 100 parts ore, 70 parts coke, 20 parts powdered pitch, and 20 parts of 5 per cent zinc-sulphate solution. These briquets are fairly strong as they come from the mold and on baking become very firm. It is questionable whether they are as good as the hot molded briquets, and the method has not been tried on a large scale.

Substituting Coal for Coke

The base of the briquets is coke, but briquets have been made by replacing coke with coking coal, the idea being that the coking coal will furnish the carbon necessary for reduction and the excess required, as well as the binding effect of the pitch. Such briquets, however, require some binder and, after baking, are shrunken and warped; for this reason they cannot successfully be used in the electric furnace. The replacement of pitch by coking coal, if it were possible, would materially cheapen the briquetting process.

Briquets have also been made with anthracite coal, which were excellent from the standpoint of strength and non-warping quality; these briquets, however, do not become conductors of the electric current until a high temperature is reached, about 1150 deg. C. This requires too great a degree of preheating. Ordinary coke briquets are conductors at 500 deg. C.

Replacing Pitch With Coal

Pitch in the briquet may be partly replaced by coking coal with good results. For instance, a mix made of 100 parts ore, 50 parts of 10-mesh coke, 40 parts of 80-mesh Pocohontas coking coal, and 10 parts powdered pitch, and one made of 100 parts of ore, 25 parts of coke, 70 parts of Pocohontas coking coal, and 10 parts of powdered pitch made good briquets after baking and gave good results on distillation. These briquets are made on the theory of replacing part of the coke and part of the pitch by coking coal, the coal acting as a binder and furnishing a part of the carbon; by this means the quantity of pitch required is reduced one-half. The proportions of coke and coal are calculated so as to leave the proper amount of excess carbon, taking into consideration the volatile matter of the coal. However, one serious objection to the use of any appreciable amount of coking coal is the fact that the products of the distillation of the coal are objectionable during the distillation of the zinc, and the relatively small saving of cost gained by its employment may be more than counterbalanced by the increased difficulties of condensation.

Baking the Briquets

The purpose of baking the briquets is to coke the pitch; the temperature required to do this varies somewhat with the time of baking. For a 9.25- by 22-in. briquet, a baking period of 6 hr., and 500 deg. C. for 2 hr. near the finish, is about equivalent to a baking period of 8 hr. with a temperature of 450 deg. C. for the last few hours of the operation. The briquets must be kept from oxidizing during the baking; that is, they must be under neutral or reducing conditions. Baked briquets have a density of 98 to 115 lb. per cu.ft. dependent on the ore and on the proportions of the mixture.

At the East St. Louis plant, the briquets to be baked were stood on end on platform cars holding twenty briquets. Each briquet was set within a light sheet-iron cylinder 12 in. in diameter and 26 in. high, and the space between the briquets and the cylinders was filled with crushed coke. The car was then placed in one of the ovens, which formed part of the drier. The two ovens were near the head of the drier, which

was the firing end. The products of combustion passed both over and below the baking oven by specially constructed flues. When a load of briquets had been baked, the car was withdrawn and replaced by another. The period of baking was about 7 hr., and the maximum temperature reached at the end approximately 500 deg. C. A briquet that has been baked for the proper length of time at from 450 to 500 deg. C. is very hard and firm and may be thrown violently from the car to the floor while hot without injury.

The briquet during the baking passes through a weak stage, which is due to the condition of the pitch and continues during the baking until a temperature of about 300 deg. is reached. From this temperature up to 500 deg., there is a constant increase in strength as the pitch becomes coke. It would be desirable to eliminate the baking of the briquets as a separate operation and conduct the process by placing the raw briquets on the furnace base and do the baking as part of the furnace operation. In the operation of the furnace, the highly heated retort from a finished charge is transferred by the crane to the new charge on the second base. The heat stored in the retort is sufficient to bake a charge of raw briquets, but the weight of a column of briquets is such that the bottom briquet of the column will collapse in the weak stage. When the rate of heating is very rapid, a hard shell is formed on the briquet's exterior columns of the furnace charge immediately adjacent to the hot retort walls before the interior becomes sufficiently heated to be weak; this shell will sustain the briquet during the critical stage. The interior columns of the charge, however, are heated more gradually from the retort walls and do not form the hard shell, therefore they will collapse at the critical stage. It may be possible, under certain circumstances, to make a briquet that will not have to be baked in a separate operation.

Resistivity of Briquets

The resistivity of hot briquets (900 to 1100 deg. C.) depends on the amount of coke used and the nature of the residue of the ore; it will range from 0.015 to 0.04 ohm per cu.in. The resistivity of the raw briquet is very high (26 to 30 ohms per cu.in.). This resistivity drops slowly until the pitch is coked at about 450 to 500 deg. C., when there is a sudden sharp drop to 0.6 to 0.7 ohm per cu.in. Fig. 3 shows a typical resistivity curve of distilling briquets.

Briquets made from ore, coke, and pitch become practical conductors at between 450 and 500 deg. C. Briquets in which part of the coke is replaced by bituminous coal do not become conductors until a temperature of 620 to 750 deg. C. is reached, depending on the proportion of coal used. Briquets where the coke is replaced by anthracite do not become conductors until about 1150 deg. C. is reached. This is too high for the proper working of the process, for the briquet would have to be reheated, even after baking, to this temperature by means of retort before the electric current would pass, and 1150 deg. C. is the temperature at which distillation is very active.

The East St. Louis Plant

The large-scale experimental work was carried out in specially erected buildings in East St. Louis, Ill.[3] The main building and annex thereto were constructed of steel and tile, the main building being of sufficient height to permit of the operation of a 12-ton electric crane for the lifting of retorts and the handling of materials. The annex contained a small, complete machine shop, and part of the electric equipment. A separate small wooden building was provided for an experimental laboratory, and contained the small testing furnaces and the chemical laboratory. There were also bins and storage sheds for ores, coke, pitch and general supplies.

In one end of the main building was placed the coke crushing plant, consisting of a 7-in. and 10-in. Blake crusher, a 20- by 12-in. set of rolls, an inclined screen, and a return bucket elevator. Adjoining the crushing plant was a Bartlett & Snow kiln drier, which dried ore and coke, heated the ore-coke mixture, and contained two ovens for baking briquets. This drier was fired at one end by an oil burner. The drier was

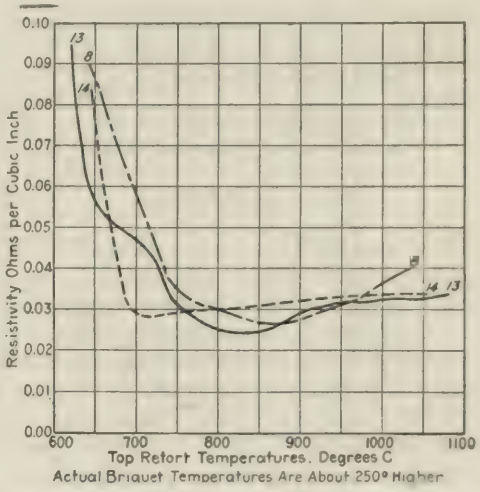

FIG. 3. RESISTIVITY CURVE OF DISTILLING BRIQUETS

especially designed as regards the setting and served the various purposes indicated. In a commercially operated plant the drying, heating, and baking would be done in separate apparatus. Adjoining the drier was the knife-blade mixer and the pitch melting kettle. Adjoining these was the tamping machine, briquet press, and tracks for the various transfer and platform cars for baking briquets. The rest of the space in the building contained the electric furnaces, the main transformers, and other electrical equipment.

Furnace C

Furnace C is the designation applied to the first furnace built. It consists of a specially constructed three-part firebrick base, the center part holding the condenser structure, and the end parts containing the electrodes and serving to support the briquet charge and the covering retort. Figs. 4 and 5 show the features of construction.

The briquet charge was set up on the left-hand base *b*, Fig. 4, the retort *a* lowered into place by the crane, the current turned, and the charge distilled. In the meantime another charge was set up on the right-hand base *c;* when the left charge was finished, the red-hot retort was immediately transferred to the right-hand base and this charge distilled. While the second charge was distilling the spent briquets on the left-hand base were removed and a new charge set up, and the operation repeated. Oil burners were provided at four places under the vapor boxes *o*, the products of com-

[3] See "Fulton's Electric Zinc Furnace," Met. & Chem. Eng., vol. 18, p. 539 (May 15, 1918); also vol. 16, p. 158 (Feb. 1, 1917).

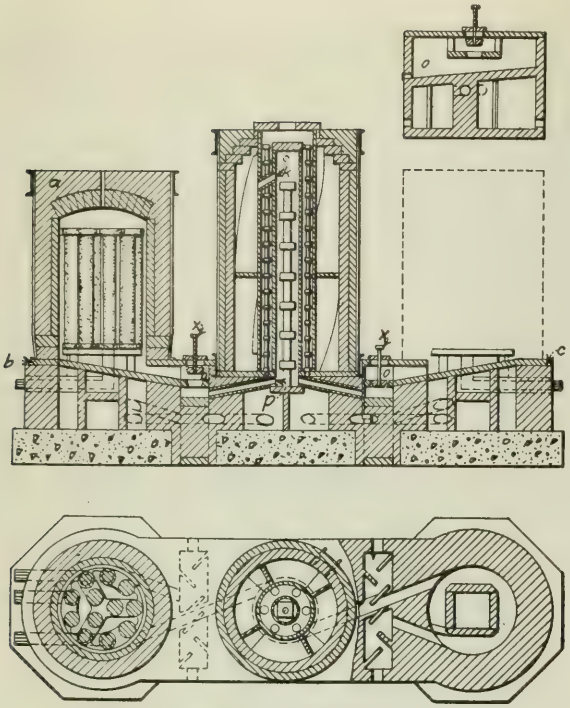

FIG. 4. FURNACE C

bustion from two of these burners passing by flues under the electrode supports in the retort bases, thence through the central flue in the condenser structure, to the air. The products of combustion from the other two burners passed from under the vapor boxes directly to the central flue of the condenser. The idea was to preheat the retort bases and the condenser to the proper temperature for the distilling operation and prevent the formation of blue powder in the condenser at the start.

The necessity for proper temperature conditions for successful spelter condensation in the condenser were fully recognized. In case radiation from the condenser walls should be insufficient to maintain proper temperature conditions within the condenser during the continuous operation of the furnace, due to the heat involved by the condensation of the large volumes of zinc vapor, the heating flues could be turned into cooling flues by the shutting off of the oil burners and closing the two retort base flues. The volume and surface of the condenser were designed on the basis of the relation of these factors to the amount of vapor, as found in the present-day retort and condenser of the standard zinc-distilling furnace. The condenser was provided with three platinum-rhodium thermocouples, one at the top and one at the bottom of the central chamber *p* (Fig. 4), and one at the bottom of the outer annular chamber. The retort was provided with two pyrometers, embedded with the refractory lining within ½ in. of the interior surface, one at the top and one at the bottom. The readings of the retort pyrometers were about 250 to 300 deg. C. below the actual briquet temperature but, with this correction known, these readings served as a perfect guide in the operation of the furnace.

Details of Construction

The retort consisted of a 0.25-in. steel shell stiffened at the top by a 12-in. channel, to which were bolted heavy cast-steel hooks, which engaged the chains of the bail by means of which the retort was lifted by the crane. The bottom of the shell was drawn in 1 in. and then flanged outward for stiffening; the contraction was for the purpose of holding the refractory lining firmly in place. The bottom of the lining was a circle of firebrick blocks 9 in. high and 13.5 in. wide, the full thickness of the lining. On these was built the interior lining of high-grade firebrick, 4.5 in. thick, the space between these and the steel shell being filled with 9-in. sil-o-cel brick and loose sil-o-cel. The roof was a firebrick dome, covered with loose sil-o-cel. The interior diameter was 48 in., and the interior height from the base to the lowest point of the dome was 72 in. The clearance between the briquet columns and the lining of the retort was 2.5 in. The clearance between the columns was about 2 in.

The electrode construction is shown in Figs. 6 and 7. Four graphite electrodes *F*, Fig. 7, 6 in. square and finished to cylindrical ends for the attachment of the electrode holders *G* passed into the furnace base through the opening *E*. On these electrodes were set 6-in. graphite risers, which reach the level of the furnace base through the openings *A*, Fig. 6. These plugs were later replaced with 9-in. plugs. A seal was made by filling in the space between the plugs and the walls of the openings with finely crushed carbon. In the first operation of the furnace, a special firebrick block was set on the base of the furnace, as shown at *C*, Fig. 1, through which the vertical plugs passed to make contact with the graphite blocks *A*, on which the columns of briquets were set. The purpose of this firebrick was to prevent a short circuit in the case of a condensation of zinc on a cool base. It was found unnecessary, so the graphite blocks *A* were set directly on the base in contact with the vertical riser plugs.

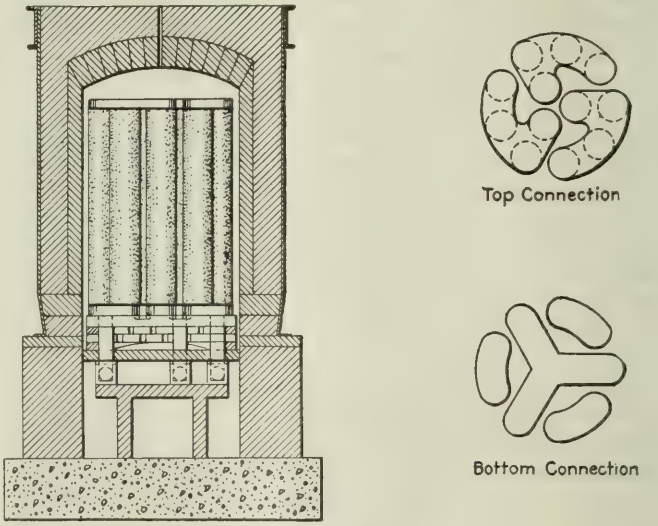

FIG. 5. FURNACE C

The top connections are also made by 5-in. graphite blocks *D*, as shown in Fig. 1. Fig. 5 shows the arrangement of the bottom blocks and of the top blocks on the "Y" connection. As shown in Figs. 6 and 7, the furnace has four electrodes. One of these is the neutral, which is brought to the exterior of the furnace to provide for an extra connection in case of a breakdown.

In order to insure perfect contact between briquets, a paste consisting of 50 parts tar oil and 35 parts of finely ground graphite was rapidly applied, hot, to the ends of the briquets by a stiff broad brush or a trowel. It had excellent adhesive properties and when

FIG. 6. BASE OF FURNACE C

baked was as good a conductor as the briquet, or better. A number of charges built up of whole briquets and briquets broken into a number of pieces, making numerous contacts with the use of this material, passed through the distillation perfectly. This is a very severe test of the process from an electrical standpoint.

Electrical Equipment

The electrical equipment for furnaces designated as C, D, and E was the same, and consisted of a General Electric 150-kw., three-phase transformer and a polyphase induction regulator. Sixty cycle current at 1300 volts was stepped down to 220 volts by transformers outside of the building and passed to the regulator placed in one corner of the main structure. From this, cables in underground conduits led to the transformer pits located at the end of each retort base. The transformer was placed in this pit and connected to the primary cables from the regulator and the secondary leads of the transformer to the furnace electrodes. When a charge was distilled, the connections were broken and the transformer lifted by the crane and transferred to the pit at the other retort base. The secondary terminals of the transformer were brought out to a terminal board attached to the transformer and were so arranged by means of heavy copper links, which could be rapidly changed in position, that the three main secondary taps leading to the electrodes of the furnace by heavy flexible cables could be at voltages of 27.5, 55, 110, and 220. By means of the regulator, the voltage adjustment between these ranges was practically continuous and a maximum voltage of 262 and a minimum of 22.5 could be obtained with a primary line voltage of 220. The power company employed boosters on its line so that a line voltage of 300 volts was sometimes available. The voltage at the electrodes with the Y set up was, when beginning operations with a cold charge, sometimes as high as 300. With hot retorts, however, the voltage would be about 150 at the start, with an energy input of 120 to 150 kw., and lowered to from 75 to 90, and the energy input used was from 122 to 184, the latter for only short periods of time, as this intensity overloaded the transformer. The electrical equipment was somewhat under capacity and the furnaces could easily take 200 to 250 kw., as was demonstrated later with new equipment on furnace F. The low kilowatt input for furnaces C, D, and E accounts for the somewhat higher distillation periods (more than 8 hr.) and also the larger power consumption, due to increased radiation losses on account of the unnecessarily long time. All electrical instruments and switches were located in the shop annex, and the furnace was electrically operated from this place.

(Part II, dealing with the operation of the furnaces and general characteristics of the process, will be published in our next issue.)

FIG. 7. ELECTRODE CONSTRUCTION FURNACE C

Sulphur to Compete With Iron Pyrites

Changed conditions since the war will bring about very shortly the substitution of brimstone for much of the sulphur which heretofore has been recovered from iron pyrites, it is believed in Washington. The amount of labor with its attending cost, which must be expended in the mining and treatment of pyrites is the more important factor contributing to the change. The high transportation rate is also a factor, especially in the case of pyrites imported from Spain.

On the other hand, the mining of sulphur by the Frasch process requires a much smaller proportionate expenditure for labor. The erection of the large plant on the newly opened sulphur deposits at Matagorda, Tex., as well as the large capital expenditures represented by the plants in Calcasieu parish, La., and at Freeport, Tex., is expected to necessitate the operation of these properties. It is believed that the pure sulphur from these sources can be sold from this time on in successful competition with pyrites.

It has been in the past the attitude of the Union Sulphur Co., which operates the Louisiana properties, to restrict its sales of sulphur to the industries requiring high-grade material. That company never has shown a disposition to enter the field where the lower-grade material has sufficed as well. In this stand the company has had the encouragement of the United States Geological Survey. There always has been much uncertainty as to the reserves of pure sulphur, and it has been a very general desire to safeguard this material against future needs. The development of seemingly very large sulphur deposits in Texas and the fact that no signs of exhaustion are appearing in Louisiana, despite the enormous output, are tending to overthrow efforts to reserve this sulphur for the higher class uses. In addition, there is the important economic question of securing a return on the money invested in these sulphur properties.

Fusibility of Coal Ash From Eastern Coals*

By W. A. Selvig, O. C. Brown and A. C. Fieldner

THE Eastern coal province, which includes the anthracite regions of Pennsylvania and Rhode Island, the Atlantic coast region of Virginia and North Carolina, and the great Appalachian region, contains the best known and most extensively mined coals in the United States.

Previous papers[1] gave a description of the standard gas furnace method used by the Bureau of Mines in making ash fusibility tests, a discussion of the relation of fusibility tests to clinker formation, and tables giving results obtained for West Virginia, Pennsylvania and Mid-Continent coals.

This paper includes a table giving the results obtained for all coals tested from the remaining States of the Eastern coal province and includes coal from Ohio, eastern Kentucky, Virginia, Maryland, Tennessee and Alabama.

No coals from Rhode Island, North Carolina or Georgia are represented. The States of Rhode Island and North Carolina are of little commercial importance as coal producers.

Interpretation of Fusibility Table

The samples represented are standard mine samples collected by representatives of the Bureau of Mines, the U. S. Geological Survey, or by the various State Geological Surveys, according to the methods used by the Bureau of Mines.[2]

NOTE.—A plus sign (+) placed before a given value denotes that the true value is above that indicated.

The arrangement in the table of the coal beds in each State is alphabetical. The number of mines sampled, number of samples represented, average softening temperature in degrees F., per cent ash and per cent sulphur in the dry coal are tabulated for each bed tested. Average values for each mine were computed from the individual samples, and from these values averages representing each bed were obtained. It is evident that the greater the number of mines sampled, the more representative are the average values for the beds. This should be kept in mind, as in many instances the average values given for the beds represent only a few mines, and are then not truly representative of the coal bed.

The point taken as the softening temperature is that at which the ash when molded into solid triangular pyramids $\frac{3}{4}$ in. high and $\frac{1}{4}$ in. wide at the side of the base, and mounted in a vertical position, has fused down to a spherical lump. Samples remaining unfused at 3010 deg. F., which was the highest temperature attained in the test, were marked plus 3010 (+3010), and used as such in figuring the average values for the mine from which the average values of the beds were computed.

For convenience in discussion, the order of fusibility of coal ash from the various coals of the country may be divided into three groups, as follows:

Class 1, refractory ashes, softening above 2600 deg. F.

Class 2, ashes of medium fusibility, softening between 2200 and 2600 deg. F.

Class 3, easily fusible ashes, softening at a temperature below 2200 deg. F.

Conclusion

The coals of Ohio which were tested gave ash of medium fusibility; the average values of the different beds come mainly in class 2. The softening temperatures of the ash from coals of eastern Kentucky and Virginia cover a wide range of fusibility, from readily fusible ashes coming in class 3 to refractory ashes coming in class 1. Many of the coal beds of Maryland which are represented give coal having a refractory ash coming in class 1 or in the upper part of class 2. The coals tested from Tennessee and Alabama come mainly in class 2, giving ash of medium fusibility, though both class 1 and class 3 are represented.

Who Has Title to This Benzyl Chloride?—Matters of Agency and Title Discussed

IN AN action for the purchase price of 4700 lb. of benzyl chloride and for the cost of 44 carboys purchased at the request of and for the benefit of the defendant, the defendant set up that it acted only as agent of a disclosed principal, M. Naef & Co., of Switzerland. The court said this claim was not sustained by the evidence. The oral contract as testified to by the plaintiff was confirmed by a note written by the defendant, as follows: "We hereby guarantee to pay for 2 tons benzyl chloride 97 per cent at $1.75 per lb., f.o.b. New York, to be shipped to Messrs. M. Naef & Co., Geneva, Switzerland, as per instructions, upon presentation of bill of lading or dock receipt." (176 N. Y. S., 850.)

The substance of this note is the agreement of defendant to pay upon presentation of the documents. The use of the word "guarantee" does not necessarily import a secondary obligation, said the court. It is only an inference that might be drawn from the use of that term to indicate that the defendant was acting as agent for the Swiss firm. There is nothing on the face of the contract to indicate such to be the fact. It takes more than this to require the determination, as a matter of law, that plaintiffs, in the troubled times of war and the uncertainty of ocean transportation, were entering into a contract with a foreign house, said the court. At the most it was a question of fact for the jury to determine, and it having decided that the Swiss house was not a principal its verdict on that point was not disturbed.

Provisions of the Contract

The contract provided that the price was to be paid upon presentation of a bill of lading or dock receipt; but there was evidence that the defendant, not having received shipping instructions, directed the plaintiffs to place the goods in a public warehouse for it and to "bring up the documents." This was a warehouse receipt, and it is upon an alleged compliance with this direction that the plaintiffs recovered a judgment for the price of the goods in the lower court. Now, on Aug. 30, 1915, the merchandise was on storage under a non-negotiable warehouse receipt issued to plaintiffs. The plaintiffs tendered this receipt to defendant and demanded a fulfillment of the contract. The defendant refused to accept the receipt, claiming the goods already to be its property. It made the additional claim that such refusal was justified on two grounds, first, because the plantiffs had already defaulted and the defendant had rescinded, and second, because the receipt was non-negotiable.

Rulings of the Court

To the first claim the court answered that there had been no default on plaintiffs' part. For on Aug. 13, the defendant required a sample of the goods to be submitted to a chemical test, and told the plaintiffs that the test would require a week or 10 days. Thereafter, on the 16th, the defendant appeared with a certified check for the purchase price, which he tendered to plaintiffs and demanded immediate performance. The inference is reasonable that the defendant, having learned that plaintiffs had not the goods then, made the tender for the purpose of putting plaintiffs in default. On this point the court held that the plaintiffs, in the circumstances, had a reasonable time for compliance, and that the demand without notice was ineffective.

As to the second claim of defendant the court said that since it was agreed that the delivery should be made by a delivery of the warehouse receipt, it could be made as well by a non-negotiable as a negotiable receipt. To place defendant in possession of the goods, a written order by plaintiffs, as well as the non-negotiable receipt, was necessary. But the refusal to accept, on the ground that the goods were the property of the defendant, waived all other objections which could have

been obviated at the time. Said the court: "As the objection that plaintiffs had defaulted rested on an unreasonable tender and demand by defendant, not made in good faith for the purpose of carrying out the contract, but in an artificial attempt to put plaintiffs in default, so the objection that a non-negotiable receipt would not give defendant possession without a written order is an afterthought without substance."

However, said the court, the case turns on the question of title to the goods. If the plaintiffs offered a warehouse receipt that covered their own goods, the tender was sufficient to pass title. If the goods were already the property of the defendant, or if the plaintiffs did not own them, the tender was obviously ineffective. The fact that plaintiffs had possession is presumptive evidence of ownership, but the presumption may be rebutted. On Aug. 16 these goods were on storage with the Continental Warehouse Co. under a negotiable receipt issued to the Behre Chemical Works, which manufactured the goods. On the same day that receipt was voided and another issued to the Franco-American Chemical Co. The defendant offered evidence that it had purchased the goods from the Franco-American company and paid for them. The plaintiffs, under a writ of replevin, seized the goods, took them from the custody of the Continental Warehouse Co., stored them in the Knickerbocker warehouse, obtained a warehouse receipt for them, and tendered it to defendant in fulfillment of the contract.

Possession Only a Presumption of Ownership

Plaintiffs' possession of the goods establishes only a presumption of their ownership. Plaintiffs took the goods from the possession of the defendant by a writ of replevin which is provisional only and does not determine ownership in itself. The plaintiffs claim that they bought the goods from the Behre Chemical Works, which manufactured them; that the defendant secretly diverted them to itself by connivance with the chemist of the Behre Works; that by several pretended sales, one by the Behre Works to a man named Brett, another by Brett to the Franco-American company, another by the Franco-American company to defendant, the appearance was created that defendant owned the goods, having acquired title from the Behre company; but that as matter of fact the plaintiffs had secured title to the goods from the maker, and none of these acts and sales could divest their title; but they offered no evidence sufficient to establish the crucial fact—that is, that they obtained title from the Behre Chemical Works.

Plaintiffs Had No Title to Pass

Were these charges true, it would indicate as truth what the lower court referred to as defendant defeating plaintiffs' performance with the purpose of cutting out their profits. But this was not an issue in the case. This action was for the price of goods sold. In it the plaintiffs must show that the sale passed the title from them to the defendant. On this crucial test the court held that the evidence was lacking to show that they had any title to pass. The plaintiffs did not show a contract with the Behre Chemical Works whereby they obtained title to the goods. No witness was called from that company. Certain telephone conversations between the parties to this suit were not evidence of the point here involved. Therefore the court granted a new trial to clear up title.

Fumes and Gases From Smelter

In an action to recover damages for injuries to growing crops and live stock alleged to have been caused by fumes and gases from defendant's smelter, the Supreme Court of Kansas held that the facts were sufficient evidence to sustain the findings and judgment for plaintiff. (179 Pacific, 342. Courtney vs. American Zinc, Lead & Smelting Co.)

From the facts it appears that plaintiff was in possession of a 12-acre tract adjoining defendant's smelter on the east which he had rented for a number of years and upon which there was growing an acre of strawberry plants, a number of bearing grapevines and various other crops. On another tract near by were bearing peach trees and an orchard. Three or four blocks west of the smelter he owned several lots upon which there were growing strawberry plants. Another tract of 40 acres was used by plaintiff as a pasture.

The petition alleged and plaintiff's evidence tended to prove that smoke and fumes were blown over each of these tracts at different times and that smelter smoke contains sulphur, arsenic, lead and zinc in various combinations, all of which are likely to poison animals and to destroy growing vegetation.

Defendant contended that because plaintiff's evidence showed that his strawberry plants were in excellent condition when they were mulched down in the fall of 1916, the jury was not justified in arbitrarily saying that they must have been injured by something from the smelter because they did not produce a good crop in 1917. It further contended that its demurrer to the evidence should have been sustained because of the absence of any evidence that the animals died from any poison that came from the smelter and because of the testimony of plaintiff's two veterinarians, who were careful not to state their positive opinions, on cross-examination, that the animals died from smelter poisoning.

The court, however, said these two witnesses were not called to testify as to their opinion upon the disputed fact, but to show that fumes given off by smelters sometimes contain sulphur, arsenic, lead and zinc and their combinations, and that any and all of these might poison animals. It was for the jury to say, in view of all the testimony, including that of the experts, whether or not the symptoms exhibited by the animals were caused by smelter poisoning.

The Rule of Law Applicable

The court announced the rule of law applicable: "A plaintiff sustains the burden of proof when he shows that at the time his plants were destroyed and damage suffered the defendant's factory was freely emitting fumes, gases and acids which are destructive of plant life, and that the wind was blowing the fumes, etc., toward his premises, some 900 ft. distant, and that there was no other known agency of destruction existing in the vicinity."

It was further urged that the evidence of the veterinarians, that in their opinion the stock in the vicinity of the smelter had been made sick from smoke and fumes from the smelter, was incompetent without proof that the smoke and fumes contained deleterious substances, or until there was expert evidence showing zinc, lead or sulphur emanated from the stacks. The court held it unnecessary to show the precise nature of the gases and fumes which came from the stacks of the smelter.

Synthetic Cast Iron*

A Continuous Process of Rapid Carburization During Melting of Steel Turnings, Producing Cast Iron and Semi-Steel of Exceptional Purity and Exact Chemical Analysis for Manufacture of Heavy Shells and High-Grade Castings

By CHARLES ALBERT KELLER

SYNTHETIC cast iron is the term by which, since the commencement of its manufacture in the electric furnace, the author has always described the iron obtained by the recarburizing melting of steel turnings. This term has since passed into metallurgical currency, and has now become generic.

The novelty of the manufacture of "synthetic cast iron" consists in carburizing iron and steel scrap, and more particularly turnings, by melting these materials in the presence of carbon, which is introduced simultaneously with them in the melting appliance. The electric furnace is plainly indicated as best fulfilling all the conditions required for the carrying out of this metallurgical operation.

From the outset of the manufacture of steel in the electric furnace there had been obtained, incidentally and without any practical importance being attached to it, the carburization of steel to cast iron composition. Apart from this, and indeed long before it, the process of carburizing iron up to saturation point was well known. No advantage was, however, derived from these facts, as the carburization of a bath of steel in a covered-in furnace, obtained by the various known methods of carburization, such as the introduction of dense conglomerates of carbon and iron (carburite) or pressed blocks of carbon and cast iron, was only practiced with the object of obtaining steel, and moreover, these processes are neither convenient, practicable, nor economical when carburization is carried to the extent of producing cast iron. Only a process of continuous carburization, effected during the course of melting a mixture of steel turnings and carbon,[1] could conduce to an economic method of producing synthetic cast iron with a commercial future capable of development as other than a mere war emergency.

Advantages of Continuous Carburization

The preliminary melting of steel turnings in a bricked-in furnace necessitates, indeed, the consumption of an amount of energy corresponding with the temperature which has to be developed in order to melt the steel. It must further be remembered that the thermal efficiency of a furnace of this type is lower than that of an open type furnace constantly replenished with materials for melting, and the walls of which are much cooler. On the other hand, charging turnings into a closed-in furnace, with doors, involves technical difficulties. These disadvantages are, however, but small in comparison with those accompanying the actual carrying out of the carburization in the two instances. The carburization of turnings, after melting, can only be effected by solution brought about between the upper layers of the metal and the carburants. It becomes the more difficult and the slower, the higher the percentage of carbon rises. The dense carburants employed are expensive, and the consumption of energy resulting from the slowness of the carburization becomes considerable. As the furnace has to be emptied after each heat, there must likewise be taken into consideration the heat losses inseparable from this operation, as well as the repairing of the hearth, sides and roof, none of which arises in the continuous running of an open furnace.

In an electric furnace charged with steel turnings mixed with carbon the carburization is not only absolutely controlled by the known reactions of the substances present, but it should be noted, as an important economic advantage, that the combination of the carbon with the iron begins in the upper parts of the charge long before actual fusion. Cementation intervenes from a temperature of 650 deg. upward and becomes more rapid in proportion as the temperature rises, owing to the descent of the charge.

Carburization of the iron takes place subsequently, by the contact between the solid carbon and the partially carburized metal in the course of melting, and becomes complete on full melting, the temperature of which is determined by the nature of the iron, so that casts can readily be obtained in the electric furnace at temperatures of 1200 to 1300 deg. C.

The proper working of the process in the electric furnace involves, however, other considerations. The mixture of steel turnings and carbon possessing, in itself, very high conductivity, it would become necessary, to insure normal working in the electric furnace, to use so low a potential that higher currents than those ordinarily in use must be employed. On the other hand, it would be a pity to employ electric fusion without profiting by the metallurgical advantages involved, in order to effect desulphurization. The introduction of basic slag into the charge meets these two requirements and accomplishes two results, subsidiary and supplementary to the carburization and necessary to the complete practical success of the process, namely:

(1) The lowering of the conductivity of the mass to be treated by the introduction of a non-conducting material among the conductive materials (turnings and carbon), thus enabling fusion to take place under ordinary thermo-electric conditions, and

(2) Complete and easy desulphurization of the resulting metal.

Thus carried out, the process may be described, from the metallurgical point of view, in the following terms:

The iron obtained in the presence of a sufficiently basic slag, which combines with the small amount of silica introduced, will contain practically all the substances contained in the charge, except the sulphur. There will be no increase in the silicon, and the carbon in the charge will be used up solely in carburization, without

*Abstracts from a paper read before the Iron & Steel Institute (British), September, 1919.

[1]French patent, Charles A. Keller, No. 405277 of Nov. 10, 1908, and certified addition No. 19358 to patent of Sept. 11, 1913, and English patent No. 22692 of Oct. 8, 1913.

any appreciable intervention of the silica. White cast iron can thus easily be obtained with ordinary steel turnings. With turnings containing 0.44 per cent of silicon, 0.55 per cent of manganese, and 0.07 per cent of sulphur, a white iron of the following composition was obtained:

	Per Cent		Per Cent
Carbon	3.55	Manganese	0.48
Silicon	0.52	Sulphur	traces

Hence control of the percentages of silicon and of other elements becomes easy; for example, extra silicon will result from introducing more silica into the charge, along with a corresponding amount of carbon for reducing it. The percentage of silica in the slag will vary according to the percentage of silicon in the iron.

The certainty with which the above considerations can be relied upon allows of the process of manufacture described by the author being regarded as complying absolutely with the predetermined calculation of the charge, and as corresponding absolutely with the estimated amount of the elements contained in it. He can afford a proof of the truth of this conclusion by adducing an instance of an electric furnace with a capacity of 80 to 100 tons per 24 hr., which has not given rise, over a month's working and while specially watched for that purpose, to variations exceeding 0.25 in the results of carburization and of siliconization respectively.

Help of Chemical Laboratory Necessary

It will have been thoroughly understood from what has been said that control of the composition of the slag must be strictly exercised; also that the amount of carbon introduced must be accurately known. The process, being one of great accuracy, is correspondingly highly sensitive. It is necessary, therefore, to rely entirely on the help of the chemical laboratory.

The carbon employed for carburizing should correspond, so far as its physical condition is concerned, with the size of the steel turnings, so that the contact between the particles may be as perfect as possible, and so as to facilitate carburization in the higher portions of the furnace charge. Small coke is highly suitable, and so is wood charcoal. Either may be used, according to price and to the degree of purity sought.

Simplicity of Operation

The system that has been described is one of extreme simplicity. It does not require any skilled workman, as the results sought are independent of any technical manipulation except in so far as the preparation of the charge is concerned, and depend entirely on an accurate knowledge of the composition of all the components.

The electric furnace, fed continuously by the charge, works regularly and with very small losses, as the heat transmitted by the electric hearth situated immediately beneath the charge is, to a very large extent, utilized in heating up the materials, and effects a preliminary carburization prior to melting. This enables the consumption of electrical energy to be reduced to as little as 675 kw.-hr. per ton of pig in a 2500-kw. furnace of 80 to 100 tons. Maintenance of a furnace, working in the manner described, is barely appreciable, seeing that with a six months' campaign at Livet the above furnace did not require any repairs either to linings, shell, or any other part. The lining only needed some attention when the furnace was put out of action owing to the water power supply failing.

The author feels it unnecessary to emphasize too minutely the advantages arising from the profound difference that exists between obtaining casting metal by the slow carburization of previously melted metal by contact between carbon and the bath (solution of carbon in liquid steel), and obtaining casting metal by the method described, based more especially on contact, at a high temperature, between solid or pasty metal and solid carbon. They are determining factors both from the standpoint of economics and of metallurgy.

Economic Considerations

The fundamental economic considerations in the manufacture of synthetic pig are as follows:

1. The electrode consumption can be lowered to as little as 6 kg. per ton, with electrodes of good quality.
2. The consumption of unoxidized turnings is 1050 kg. per ton of iron, a figure which, even with moderately rusty scrap, becomes only a little over 1100 kilograms.
3. The amount of coke with 80 per cent fixed carbon required to produce a ton of strong pig iron with 3 per cent carbon and 1.75 per cent silicon, starting with normal turnings of shell steel, is about 80 kilograms.
4. A furnace of the 80- to 100-ton type should be provided with mechanical appliances for upkeep and charging, so that its operation does not require more than fifteen workmen, for the preparation of the charge by hand, for charging, and for regulating the furnace.
5. Tapping, and loading on trucks as required, need seven men per unit, and handling in the stockyard another two men.

Commercial Applications of Synthetic Cast Iron

The general economy of the process, combined with the simplicity of the method of carrying it out, leads the author to believe that while synthetic iron found a very wide field of application during the war, owing to the very large production of steel turnings derived more particularly from shell manufacture, it will find no less a field after the war in, for example, producing those steel-like qualities of material required for highly resistant mechanical parts.

The most obvious plan to adopt is to lay down a foundry for such parts adjacent to the synthetic cast-iron plant, as has been done at Livet. In such a case the foundry iron from the primary furnace may, if preferred, be made use of by transferring it to an electric mixer which can mix several casts and thus keep any quantity of metal ready for castings.

The manufacture of malleable cast iron is likewise easily accomplished in the electric furnace, as the general quality of the steel turnings enables the low percentage of silicon and manganese required to be readily obtained, the reduced percentage of carbon present being dependent on the composition of the charge. It will also be seen that synthetic iron may find a further field of application in the manufacture of special pig, by means of special additions, such, for example, as nickel, chromium, etc. In such cases benefit will be derived, in making this kind of iron, from the absence of hydrogen, nitrogen, carbonic oxides and occluded air.

The materials required for national defense were generally confined to cast irons whose purity, in regard to phosphorus, corresponded practically with that of the steels used in the production of synthetic cast iron, seeing the sources whence these steels were derived. After the war the situation will be altered. Steel turnings will

come from a variety of sources, and will no longer be under the same guarantees, so that very often it will be their dephosphorization which will be of chief importance when a cast iron of high quality is required.

Dual Process for Dephosphorization

The metallurgical value of the results obtained by the process alter completely when it becomes a question of dephosphorization, which the author has practically accomplished by means of a dual process.

In the first place, the steel turnings are melted in the presence of a small quantity of carbon and of a basic oxidizing slag. It is necessary to aim at a critical carburization which must be as high as possible, in order to lower the temperature of working and to facilitate the casting of the metal, while at the same time effecting dephosphorization. A percentage of 1 or slightly over realizes this object.

This first-stage dephosphorized metal, containing low percentages of silicon and manganese, is, according to circumstances, either cast into small ingots which are subsequently melted in an open furnace, mixed with the necessary additions of carbon and a desulphurizing slag composed of materials containing exceedingly little phosphorus, or else poured into a second furnace of the bricked-in type, and covered with a layer of anthracite for recarburizing. The synthetic cast iron produced is controlled in respect of its silicon and manganese percentages by the addition of oxides and of a corresponding amount of reducing carbon, in the ordinary way. This mode of working somewhat increases the cost of production during the first phase, and further necessitates, in the second phase, a converting-cost equivalent to that of manufacturing ordinary synthetic cast iron. About 1500 kw-hr. must be allowed for the two operations.

The higher costs of manufacture are balanced by the higher value conferred on the synthetic cast iron by reason of its extreme purity in regard to phosphorus, and likewise its purity from sulphur and its uniform composition in respect of silicon and manganese. From the commercial point of view such material can compete with Swedish iron.

Alternative Process for Steel From Steel Turnings

The author concludes this account of the chief metallurgical results obtained with synthetic cast iron by describing an alternative process which he has been led to contemplate in connection with the manufacture of steel from steel turnings.

As in the preceding example, the steel turnings are melted in an open furnace fed by the charge, but the slag, instead of being oxidizing, is desulphurizing, and the quantity of carbon introduced with the charge should be sufficient to reduce the oxides in the turnings and to carburize the metal to an extent distinctly above the percentage of carbon sought in the steel, so as to facilitate the pouring of the desulphurized metal and to allow of an oxidizing working in the second stage of the operation.

For example, if a steel with 0.5 per cent of carbon be required, the metal in the primary furnace may be poured at 1.5 per cent of carbon. It will, as has been said, have been freed from sulphur during melting.

The secondary operation, which can be either in an open-hearth furnace or in an electric furnace, refines the metal and brings it to the required carburization, while at the same time dephosphorizing it. It then remains to bring the metal to the proper carbon content in the ordinary way by final additions.

Operations at Keller Leleux Co. Works

The production of synthetic cast iron during the war has been considerable. It is not possible for the author to estimate at the moment how much has been produced at works other than those administered by the Keller Leleux Co. at its works at Livet, Nanterre, and Limoges. The production of these three works alone exceeded 150,000 tons, while it should further be pointed out that Nanterre has been devoted to other manufactures within the last eight months. It goes without saying that such an output could not be obtained solely from existing plants, but required a special industrial effort for the creation of new plants.

Early in 1914 a scheme for a works for the manufacture of malleable iron by this electric process was about to be carried out. This was, however, interrupted by the war. Directly after the specifications for projectiles of semi-steel appeared, the author took steps to produce a metal complying with the conditions laid down by the French Ordnance Department. By November, 1914, such an iron had been produced and investigated, corresponding with the following composition:

	Per Cent		Per Cent
Carbon	2.9	Phosphorus	0.05
Silicon	1.75	Sulphur	traces
Manganese	0.50		

The test results obtained were as follows:

Tensile strength, 50 kg. per sq.mm. (71,000 lb. per sq.in.); impact resistance, 60 blows (equivalent to fall of a 12-kg. tup from a distance of 89 cm. on a test-piece measuring 40 by 40 mm., resting on two knife edges 16 cm. apart, the distance of fall increasing 1 cm. at a time until rupture occurs), whereas the ordnance requirements only specify a minimum of 25 kg. per sq.mm. for the tensile strength and 18 blows (equivalent to 44 cm.)

Works at Livet

The first electric furnace, of 20 tons, was started in 1914. The uniformity of the iron and the tensile qualities obtained led to its being immediately considered from the standpoint of shell manufacture. The Ordnance Inspection Department, after due examination, showed itself favorable, and before the end of 1914 the first series of 220-mm. shells of semi-steel yielded excellent results at the Bourges proof range.

Orders from the Department were the immediate result of these favorable trials. The manufacture of 220-mm. shells of synthetic semi-steel was thus undertaken at Livet on a commercial scale from the commencement of 1915. A complete foundry was erected and furnished with electrical furnaces for the refining of the iron, and the production, which was in the first instance at the rate of 50 shells per day, was raised in 1916 to three hundred 220-mm. shells, together with ten high-explosive 400-mm. shells requiring 55,000 kg. (60 tons) of raw metal.

Use of Electric Mixer Furnaces

In order to comply with the best practical conditions for running the foundry, the iron obtained in three primary furnaces is run into a ladle of 5 tons and poured into three 7-ton electric mixer furnaces, each taking

400 kw., to reheat the metal if necessary, and in any case to keep it hot during the period that iron is being used, and to check the quality. Despite the very uniform composition of the primary furnaces, a carbon test, which only takes 20 minutes, is carried out by the foundry staff before pouring, in addition to ascertaining the quality by a quench test which serves more particularly to check the silicon.

The mixer-container furnaces for steel are of the Charles A. Keller type, that is to say, they have a roof and doors. The electric current enters by a vertical electrode, and leaves through the conducting hearth, of the reinforced-puddle type (vertical bars plunged into tamped magnesite). A conducting hearth of this description is practically unwearable, being non-susceptible to any cracking (Fig. 1). If the bottom conducting

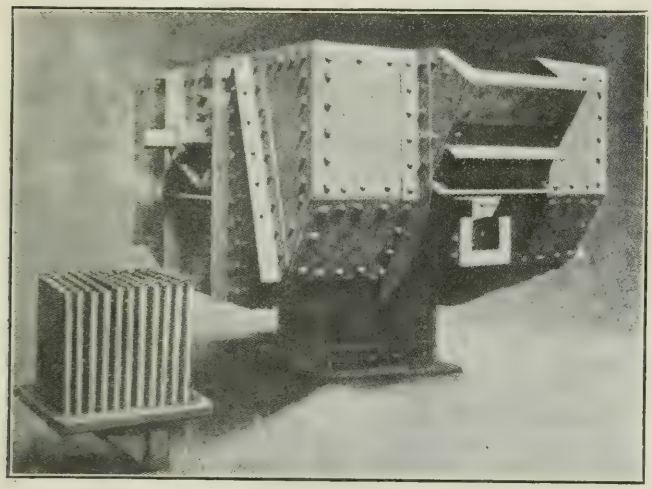

FIG. 1. FURNACE SHELL, CONDUCTING BOTTOM SHOWN SEPARATELY ON LEFT

surface of the hearth wears gradually lower, repairs are very easily effected by spreading over the bottom, while still hot, a special conducting puddle consisting of magnesite and fragments of iron mixed in tar. All holes are thus easily filled up without either the framework or the working of the hearth being interfered with in any way. From a metallurgical point of view this method of repairs corresponds in principle with that employed for the hearths of open-hearth furnaces. The furnaces are, of course, of the tilting type which allows of any quantity of metal, no matter how small, being drawn off.

The liquid iron poured in is covered with basic slag, which forms a protecting layer, preventing oxidation and breaking the electric arc. When pouring is to be done, this layer is easily retained by a little brickwork or sand pocket at the entrance of the furnace spout.

Practice has shown the advisability of interposing these mixer furnaces, which keep the metal so that it can be checked from time to time by the technical staff, who thus acquire a high degree of skill, seeing the ease with which the metal can be held waiting. Generally speaking, it may be said that the metal remains an hour in the mixer furnace, including the time of pouring, for the filling up of these furnaces is carefully adjusted to correspond with casting operations in the foundry. The metallurgical adjustments are very easily carried out, as any additions, as well as the withdrawal of the test samples, are effected through the working door. The practice described gives complete satisfaction; in particular it invariably insures uniform metallurgical results, thus eliminating all rejections due to insufficient tensile strength.

The upkeep of the mixer furnaces is but trifling. The interior lining of the mixer lasts a couple of months, and the roof over three months. The electrode consumption is on an average 2 kg. per ton of iron; the average power consumption is from 50 to 100 kw-hr. per ton, according to the conditions prevailing in the foundry. A single workman is required for the working of the furnaces, and he also looks after the tapping, the electrical manipulation of the tilting arrangements, and the taking of samples.

Uniformity and Good Quality of Product

The capacity of the electrical foundry at Livet could not keep pace with the output of casting metal, which began at 20 tons per day, was subsequently increased to 60 tons, and later on reached not less than 300 tons during the period of maximum water-power supply. Several outside works manufacturing shell were supplied with the surplus output. These firms all testify to the uniformity and excellent quality of iron supplied. The quality of the iron supplied to outside firms corresponds with the following composition, which complies with the best metallurgical practice: Carbon about 2.75 per cent and silicon about 2 per cent; so that after a cupola melting the artillery specifications could almost be met without any addition of steel, as both recarburization and reduction of silicon accompany fusion in this type of furnace. Each carload sent out was accompanied by an analytical report showing what additions of steel and of ferrosilicon might be needed. Very often no such additions were required.

This method of working usually conduced to obtaining good metallurgical results in shell foundries. The care with which the analyses were made was carried to such a point that qualities specially standardized for carbon and silicon were supplied to smelters in order to check abnormalities due to remelting in certain cupolas.

Even the enlargement of the existing Livet works has now become insufficient to deal with the increased demand for this quality of iron.

New Works at Livet

New special works were laid down in November, 1915, some hundreds of yards from the original works, with which they were connected by railway. The new works were started on July 12, 1916, first with a furnace of 80 to 100 tons, and were subsequently enlarged. The building occupied an area of 12,500 sq.m., and comprised more particularly four parallel shops. The first shop, which was 300 m. in length, and was alongside the railway, served for unloading the raw materials and more especially the steel turnings, which are handled by means of a powerful electromagnet suspended from a high-speed crane. The turnings are either used at once in the cycle of operations, or put into stock in a deep trench occupying a portion of the length of the shop, from which they are withdrawn by the same means. By this arrangement a 12-ton car can be unloaded in 20 minutes.

The second shop, which was situated between the unloading shop and the electric furnace shop, served for the preparation of the charges, which are mechanically raised by large bucket elevators to the furnace platform,

where they are tipped on to the latter by small carloads at a time and heaped around the electrodes.

The transformers are housed in sheds built on reinforced concrete foundations on the level of the platform of the electric furnaces. This arrangement possesses the advantage of leaving the second shop entirely free, and also reduces secondary distribution to a minimum. Each shed contains the transformer panelboard which is connected with the central supply by means of an armored cable, leading to a long upper gallery of reinforced concrete, in which are housed the busbars and all the switches (registering meters and watt meters). This gallery, which is just beneath the roof, is capacious enough to allow of easy access, while its position isolates it as completely as possible from dust, and prevents any danger arising to the staff.

The third shop contains five Charles A. Keller furnaces of the "electrodes in series" type arranged in line, four being of 2000 kw. and one being of 2500 kw. (Fig. 2.) The output capacity of this installation is 300 tons of synthetic iron per day. This output could not be maintained, particularly in 1918, owing to various circumstances which were, however, quite independent of the plant itself.

Loading the iron in cars is effected by means of an electro-magnet suspended from an overhead electric crane, which serves a line of railway parallel with the front of the electric furnaces. By this means a 10-ton car can be loaded in 15 minutes.

Layout of the Works

The layout of these works provides for a complete unit of manufacture, in transverse section, for each pair of furnaces, this arrangement being repeated along the whole length, and thus securing the best possible arrangement for the supply of raw materials, and for the removal of the manufactured products, each unit having lines of railway along its sides and being thus connected up with both ends of the works. The haulage of cars is effected by electrical capstans placed throughout the plant. At one end of the works a shop at right angles to the shops just described has been laid down to house electrical converter furnaces to serve a steel foundry. The special synthetic iron employed for this conversion is poured into a ladle on the side of the furnace furthest away from the pig beds. The ladle can thus be conveyed along a longitudinal pit by an electric overhead crane, so that its contents can be poured into the converting furnaces. This arrangement for casting from both of the opposite sides of the electric furnace enables the material to be cast, very conveniently, either into pigs or poured into the ladles.

At the end of the plant are two large shops intended ultimately to serve as rolling mills and to house the accessory appliances.

National Gun Foundry of Nanterre

At the end of 1916 the author was commissioned to lay down and equip the works at Nanterre for an output of 300 tons of synthetic cast iron per day, employing power derived from the sector of the Société d'Energie Electrique de la Région Parisienne.

The electrometallurgical works, known as the National Gun Foundry of Nanterre (Fonderie Nationale d'Artillerie de Nanterre), comprises seven furnaces, of which six are in operation, requiring 10,000 kw. They were built in 182 effective working days, with the wonderfully active and energetic help of the Société Générale d'Entreprises for all contract work. They were put into operation on July 3, 1917. The works, which were designed for the manufacture of synthetic steely-iron for shell manufacture, at once realized this industrial purpose. The anticipated results were, indeed, surpassed, and the quality of the iron was greatly appreciated by iron-founders on account of its uniformity and purity.

The consumption of materials per ton of pig for the 1650-kw. type of furnace employed was as follows:

Steel turnings, kg	1133	Electrodes	6.1
Coke, kg	89–95	Kilowatt-hours	815

The electrometallurgical works, which were connected to the Havre Railway, comprised an important network of sidings intended to accommodate 40-car trains. The works themselves are composed of three sets of buildings, of which the largest consists of three parallel aisles each of the same length, and the arrangement is practically the same as at Livet, which has already been described. At Nanterre, however, the electric furnace bay and the unloading bay are combined and furnished with a long-span overhead crane, which further accelerates working. The handling arrangements have been

FIG. 2. FURNACE ROOM AT LIVET WORKS

divided into two sections of 150 tons per day, each furnished with an overhead electric crane, for unloading raw materials, with an electromagnet for the turnings and a bucket grab for the other materials, while in the furnace shop there is an overhead crane for loading the pigs. The stocks of steel turnings for current use are stored at the two ends of the third aisle, and are carried to the charge-mixing shop and dropped from the electromagnets into intermediate hoppers made of reinforced concrete. The various materials, such as coke and the slag constituents, are stored in the center portion of the raw materials shop. They are crushed, after unloading from the wagons, and hoisted in large

reinforced-concrete bucket hoppers, whence they are delivered through holes in the bottoms to the trucks. The coke employed for carburization goes from the crusher to a rotary fan drier, which reduces the moisture to less than 1 per cent. Two bins are always in use for holding the coke, one full for current manufacturing purposes and the other in process of being alternately filled. This system allows of the amount of fixed carbon, as coke, which is in course of consumption being accurately known. The charge-mixing shop is adjacent to the raw material storage sheds, and comprises a longitudinal pit in which run the service trucks. These are raised by electric hoists to the electric furnace platform, each hoist serving two furnaces.

Electric Furnace Equipment

The electric furnaces are charged by the trucks being tipped on to cast-iron traveling bands, which take the material to the electrodes. The furnaces are built in line at a distance of 30 m. apart from center to center. The transformers are housed in sheds on the level of the charging platform. The distributing system for the 3-phase 5000-v. electric current consists of armored cables carried in a subterranean chamber alongside the longitudinal pit in which the trucks run, so that the manholes open into the side of the pit. Connection with incoming current and with the power station is by means of seven armored cables of 800 sq.mm. in section, of which one serves as a relay.

The electric furnaces are controlled from a control station situated between each pair and is effected by hand, the variations being slight. The arrangements for lowering and raising the electrodes are likewise mechanical. The electric furnaces are of the Charles A. Keller monophase type, with the electrodes in series.

The manufacturing plant proper ends with a shop where the electrodes are prepared, agglomerated in sets of four, the individual rods being connected with the lead-in piece by a fused joint. The blocks so formed are taken by an electric hoist to the smelting shop, and discharged on the end of the electric furnace platform, whence they run on rails to the different furnaces.

In order to provide for future urgent needs the power supply of the electrometallurgical works at Nanterre has been increased to 15,000 kw., to be used in the nine monophase 1560-kw. furnaces housed in a melting shop 175 m. in length.

The Limoges Works

Simultaneously with the undertakings created at Livet, the Keller Leleux Co., in co-operation with the Société Générale d'Entreprises, established a works for the manufacture of synthetic cast iron, the power supply being the surplus energy developed at the Eymoutiers Hydro-Electric Works, belonging to the Departmental Railway Co. of Haute-Vienne.

The electric furnace, which is one of 1000 kw., was worked in 1916 in parallel with the tramway system, practice having shown that the use of this arrangement is advantageous.

Villefranche Works

A similar plant, the power capacity of which is 2000 kw., has been laid down by the Keller Leleux Co. at Villefranche, to use the surplus power developed by the Midi Co. on its line from Perpignan to Bourg-Madame. This works has only just been completed.

It is incontestable that the war has stimulated extremely rapid development of the manufacture of synthetic cast iron owing to the abundance of steel turnings and the practical difficulties of using them before 1916, with the result that a considerable quantity of French steel turnings used to be exported, chiefly to Italy and Spain. Since that time blast-furnaces have become large consumers, and the problem of what is their best mode of utilization—either in the blast-furnace or in the electric furnace—now deserves further investigation. Questions of transport now play so considerable a part that in this as in all other cases it is necessary carefully to determine from time to time which is, nationally, the most economic method of using them.

Whichever way the question may be decided, there is no doubt that a recarburizing fusion by electric power derived from water-falls constitutes the most economical mode of utilizing such turnings, in so far as it involves a complete economy of coal. It is therefore toward electrical furnaces supplied by water power that we must look for the utilization of steel turnings, although the post-war conditions may modify the existing situation.

The possibilities connected with the manufacture of synthetic dephosphorized iron must depend in the first place on the supply of steel turnings, but ultimately on the difference between the cost of coal and the cost of developing water power. The whole of the conditions will have to be reviewed later, when war conditions have yielded to conditions of normal equilibrium, but respecting which, for the moment, all forecasts are at present speculative. It will be seen, none the less, that synthetic cast iron has filled a useful gap in the production of pure iron and has rendered valuable help to the cause of national defense.

Thermit Welding

An important development of Thermit welding in American shipyards is anticipated by the recent approval by the American Bureau of Shipping of the Thermit process for welding stern frames, rudder frames and other heavy sections on ships registered under its classification. The only qualification is that this Bureau be notified sufficiently in advance to have a surveyor in attendance during the welding operation as well as to inspect and test the weld when completed.

While the Thermit process has been used since 1903 for making marine repairs and has a great many successful welds of this nature to its credit, the process was never officially approved by the American Bureau of Shipping and most of the repairs were made on vessels not classed by it. It is due entirely to the unbroken record of successful marine welds that the Bureau now accords its official sanction to the process. According to a statement by the Metal & Thermit Corporation, there has never been a single failure of a Thermit marine weld so far as it has been able to ascertain in all the years that the process has been used under this company's jurisdiction.

Now that the United States promises to have one of the largest mercantile marines in the world and as practically all of the ships which have recently been constructed and which will be constructed in the future will be registered with the American Bureau of Shipping, the recognition of the Thermit process by that Bureau bids fair to result in many important Thermit marine welds from now on.

Recent Chemical and Metallurgical Patents

American Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Steel Refining.—WILLIAM R. WALKER of New York City patents the method of refining basic low-carbon steel by maintaining it in the ladle at a proper pouring temperature for a sufficient time to de-gasify the melt and yet under a slag so modified that rephosphorization will not result. Thus when the open-hearth is tapped the metal runs into a ladle of such size that the most of the slag overflows. The remainder may be skimmed mechanically and replaced by a molten phosphorus-free slag, or if the furnace-slag be low in phosphorus, lime may be added in the runner so it is intimately mixed with that portion of the slag remaining in the ladle, thus increasing its viscosity and consequently decreasing the rephosphorizing action at the surface of the metal. During the time the metal is in the ladle it is kept hot, preferably by electrical currents induced by a high-frequency coil placed about the ladle. (1,309,162; July 8, 1919.) The same inventor patents a quadruplex process for making acid steel of purity comparable to that of Swedish or crucible steel. After bessemerizing in an acid converter to remove nearly all the silicon in the pig, the metal is transferred to a basic open-hearth when the carbon has been reduced to about 0.5 per cent. In this way the phosphorus is removed under the ordinary basic slag of lime and iron oxide. The next step is done in a basic electric furnace, and nearly all the sulphur and remaining phosphorus can be removed under a slag mostly of lime containing from 10 to 35 per cent of silica depending inversely upon the amount of sulphur to be removed. Finally the molten metal is transferred to an acid electric furnace, and worked under a siliceous slag, containing just enough lime for fluidity yet not enough to attack the furnace lining (perhaps 75 per cent SiO_2, 25 per cent CaO or basic equivalents). This "dead melts" the metal, adding silicon reduced from the slag, which in turn replaces metal in any oxide existing in the bath. When the whole has been sufficiently deoxidized and siliconized, it is tapped and cast. (1,309,496; July 8, 1919.)

Barium Hydroxide From Barium Sulphide.—When a solution of barium sulphide of 8 to 10 deg. Bé. at 15 to 20 deg. C. is rapidly cooled with constant agitation until the temperature is reduced to 0 to 5 deg. C., almost pure crystals of barium hydroxide are deposited. These may be purified by washing with a saturated solution of barium hydroxide at the same temperature or by re-crystallization. If, however, solutions of a strength above 10 deg. Bé. be employed, the barium hydrate will be contaminated with barium sulphide in proportion to increasing strength employed. On the other hand, if solutions of a strength below 8 deg. Bé. are used, too small a proportion of pure hydroxide is obtainable. On drying the crystallized barium hydroxide in air which is free from carbonic acid, or *in vacuo*, the dehydrated barium hydroxide $Ba(OH)_2$ is obtained in absolutely pure form and can be used for the production of absolutely pure barium peroxide (BaO_2) by the usual methods. (1,316,133; EDWARD A. BARNES, South San Francisco, Cal.; Sept. 16, 1919.)

Strawboard Lining for Cyanamide Furnaces.—Originally the charge of finely ground carbide was introduced into the furnaces in a metal container. The great wear and tear on the metal containers when subjected to the high temperatures used have proved a source of serious trouble and expense, the containers becoming dented and battered through handling, making it difficult if not impossible to discharge the solid cake of cyanamide therefrom. To obviate this difficulty, particularly during the war, when the cost of the metal containers became excessive, a substitute was sought and found, consisting of a paper sleeve which was inserted into the oven and then filled with carbide, after which nitrification was started in the usual manner. This paper sleeve must be manufactured from stout paper and of definite dimensions, and even with the greatest care it would not infrequently tear or split from the pressure of the contained powdered carbide. Further, it was necessary that an annular space be left between the paper and the oven for inserting the proper equipment for placing the paper and holding it in place during filling with carbide, as well as to assist in distribution of nitrogen, and this space appreciably reduced the capacity of a given sized oven and also increased the cost of equipment and housing. By merely lining the furnace with corrugated strawboard, WILLIAM H. MIDDLETON of Niagara Falls, Ontario, finds that a given oven will hold 35 per cent more carbide than when the paper sleeve is used and 50 per cent more than when the metal container is used. The usual cylinder around the resistor is provided and, in addition, tubes of corrugated strawboard extend from the nitrogen inlet to the resistor space and to the top of the charge, so that effective distribution of the nitrogen is obtained. During nitrification the mass sinters and shrinks away from the walls, so that the ingot can be withdrawn by means of two iron hooks placed in the top of the charge before heating. (1,315,678; assigned to American Cyanamid Co.; Sept. 9, 1919.)

Purification of Partly Oxidized Resins.—As raw material for producing common resin (colophony), turpentine or natural resin in a fresh state, as obtained by collecting the same from conifers, has hitherto been used. After such collection deposits of old resin are successively formed on the trees, said resin not being adapted to be utilized rationally, since on treating the same according to known methods it gives a colophony of less or no value. This is also the case with old resin flowing out by itself and available to be collected in the woods of conifers. It has been customary to extract the old resin with alcohol, but the resin recovered in this manner is dark colored and only party soluble in oil of turpentine and linseed oil. JOHN R. KÖHLER of Stockholm, Sweden, finds that the old resin consists of a mixture of oxidized resin acids and crystallized resin acids, both constituents being soluble in alcohol. Such solvents as benzene and oil of turpentine, however, dissolve only the valuable cyrstallizable resin acids, which may be recovered as light-colored colophony of high quality. (1,316,842; Sept. 23, 1919.)

Manufacture of Hydrofluoric Acid.—Fluorspar and sulphuric acid in suitable proportions are fed into a hot stationary inclined still or retort at the upper end through a hopper. In the retort the mixture is kept constantly in motion by revolving paddles, and gradually stiffens as it moves slowly down into the hotter parts. Finally it breaks up, part into powder and part into small balls or rounded lumps. Meanwhile, the reaction between the calcium fluoride and the sulphuric acid goes on, yielding hydrofluoric acid in the form of vapor, and calcium sulphate ($CaSO_4$) as a solid residue. The former goes off through a lead pipe, while the residue falls into a water-sealed pit and is removed from time to time in any convenient way. The temperature inside the retort should not be less than 315 deg. C. at the hottest parts. The shaft carrying the paddles may be made hollow to permit cooling by water or other medium. The hydrofluoric acid being given off gradually as the mixture progresses, the process is in effect continuous, even when the raw materials are supplied intermittently. (1,316,569; EDWIN S. FICKES of Pittsburgh, Pa.; Sept. 23, 1919.)

Synthetic Steel.—CHARLES A. KELLER of Paris, France, patents a continuous duplex method of making high-grade steel from light turnings or other steel scrap. He uses an open-top shaft furnace with a non-carburizing lining, charging the iron continuously as it settles below the top. With the iron he charges granulated basic slag for desulphurizing, and enough carbonaceous material to reduce any iron oxide present with a surplus to make a fluid high-carbon steel, easily tapped from the furnace. This molten material is then transferred to a closed electric or open-hearth furnace, and held under an oxidizing slag, whereby the carbon is reduced to the required amount. Dephosphorization proceeds simultaneously in this refining furnace. (1,316,724; Sept. 23, 1919.)

Personal

Captain W. E. BROPHY, formerly of The Barrett Co. and later of the Chemical Warfare Service, U. S. A., has joined the engineering staff of Arthur D. Little, Inc., Cambridge, Mass. In the early part of the war Captain Brophy had charge of the construction and operation of the plant at Astoria, L. I., for the manufacture of high-absorbent carbon for use in gas masks, and later he designed, constructed and operated an additional unit at San Francisco.

HARLAN A. DEPEW, formerly research physical chemist of the Firestone Tire & Rubber Co., Akron, Ohio, is now with the New Jersey Zinc Co., Palmerton, Pa., engaged in experimental work on rubber compounds.

Colonel BRADLEY DEWEY of the Chemical Warfare Service has associated himself with Charles Almy, Jr., in the Dewey & Almy Chemical Co., North Cambridge, Mass., for the manufacture of chemical specialties and mill supplies.

E. W. ENGLEMANN has been appointed consulting research engineer for the Utah Copper, Chino Copper, Ray Consolidated Copper, and Nevada Consolidated Copper companies, with headquarters at Salt Lake City.

Dr. ALEXANDER L. FEILD, formerly with the National Carbon Co., Cleveland, Ohio, is now with the Electrometallurgical Co., Niagara Falls, N. Y.

Dr. LOUIS J. GILLESPIE, for the past six years investigator in the Department of Agriculture, Washington, D. C., is now professor of physical chemistry at Syracuse University, Syracuse, N. Y.

J. HARRY HUGHES, of Mobile, Ala., who served in France with the Rainbow Division, has become assistant superintendent for the Ranier Mines Corp., Wenden, Ariz.

G. E. IRONS has left the U. S. Bureau of Standards to accept a position with the American Dressler Tunnel Kilns, Inc., at New Castle, Pa., as thermal engineer.

GRINNELL JONES has severed his connection with the U. S. Tariff Commission to become a member of the faculty of Harvard University, Cambridge, Mass. He is still retained, however, on the staff of the Tariff Commission in a consulting capacity.

Lieutenant ROBERT F. LABARRON, formerly of the U. S. Field Artillery, has joined the staff of Arthur D. Little, Inc., Cambridge, Mass. Mr. LaBarron was sent to Paris after the armistice to the Ecole Supérieure des Mines, at which time he was afforded unusual opportunity to investigate the potash situation in Alsace and the general metallurgical and mining conditions of the Saar Basin with representatives of the French Government.

Dr. IRVING LANGMUIR is to be awarded the William H. Nichols medal at the March meeting of the American Chemical Society, for his paper, "The Arrangement of Electrons in Atoms and Molecules," which is the outstanding contribution to the *Journal* of the American Chemical Society, during the past year.

A. L. MERCER, for several months assistant director of sales of the War Department, has resigned to accept the presidency of the Needham Tire Co., Charles River, Mass. Mr. Mercer entered the Ordnance Department of the Army in 1917 and was commissioned Lieutenant-Colonel in the Ordnance Reserve Corps on his discharge. Prior to his military service he was associated with the B. F. Goodrich Rubber Co., Akron, Ohio.

Dr. ARTHUR W. NIXON has been appointed associate professor of chemical engineering on the faculty of Columbia University, New York City.

CHARLES F. WILLIS has become editor of the *Arizona Mining Journal*, published at Phoenix, Ariz.

WILLIAM W. WINSHIP, American manager of the Thermal Syndicate, Ltd., left on Jan. 3 for a business trip to England to visit the home office at Wallsend-on-Tyne.

C. A. WRIGHT of the Moscow, Idaho, office of the Bureau of Mines, is to succeed F. G. Moses, resigned, as hydrometallurgist at the Salt Lake City station.

Obituary

JAMES MCLEAN, vice-president of the Phelps, Dodge Corp. and director of many other companies, died on Jan. 7 of pneumonia.

Current Market Reports

The Non-Ferrous Metal Market

New York, Jan. 5:—Copper is active at 19½c. for near-by delivery, 19¾@20c. for future delivery. There has been very little trading in tin, the February-March quotation being 61¾c. Lead and zinc are both firm.

		Cents per Lb.
Copper, electrolytic		19.50
Aluminum, 98 to 99 per cent		33.00
Antimony, wholesale lots		10.12½
Nickel, ordinary		42.00
Nickel, electrolytic		45.00
Tin, Straits, spot		64.00
Lead, New York, spot		8.00
Lead, E. St. Louis, spot		7.75
Zinc, spot, New York		9.60
Zinc, spot, E. St. Louis		9.27½
Silver	(Dollars per oz.)	1.33

RARER METALS

Cadmium	lb.	$1.50 @ 2.50
Cobalt	lb.	1.90
Platinum	oz.	150.00

No. 1 comp. turnings	11¼ @ 12
Tea lead	4.65 @ 4.75
Lead, heavy	6.00 @ 6.25
Zinc, scrap	4¼ @ 4½

The Iron and Steel Market

Pittsburgh, January 9, 1920.

Visible signs are unabated of a shortage of steel, in consumers scouring the trade for any steel in stock they may uncover or any rolling space for the next 30 or 60 days. In many cases price is scarcely an object, as some manufacturing consumers are losing business through not having enough raw material for full operation. As to late deliveries, there is little interest and the market is quiet. Buyers are not anxious to act for late deliveries at this time, when steel is scarcer than it is assumed it will be later, while the mills are unwilling to sell.

Production of pig iron and steel is increasing at a more rapid rate than was expected. Despite the coke shortage, which was very acute during part of December and is not entirely ended yet, pig-iron production in December was at about 6½ per cent greater rate than in November, while the rate now is about 10 per cent above the December rate. Steel production has gained correspondingly or more. A few steel works are drawing upon pig iron stocks they chance to have. An indication that steel mill operations in the valleys now promise to be heavier in the current quarter than was anticipated is furnished by the fresh buying movement in heavy melting steel scrap in the valleys. In the past week there have been fairly heavy purchases in the district, sufficient to put the market up $1@$2 a ton, heavy melting steel being now quotable at $26@$27, delivered Pittsburgh or valley districts. Some of the valley mills had previously been taking rather a gloomy view of first quarter prospects, estimating their average operation in the quarter at not over about 75 per cent.

Any appraisal of the steel situation and prospects would be altogether incomplete, and perhaps very misleading, if based only upon the present famine conditions existing in steel and without regard to the interesting and important fact that by comparison with present very active conditions in industry generally and with the productive capacity the order books of steel mills are very light. Never before in active times have the steel mills as a whole had such a small volume of business on books in proportion to their capacity as at the present time. The Steel Corporation is sold the farthest ahead, and yet it has some open capacity for second quarter in certain products. So far as is known not an important independent is moderately well filled for second quarter, and many have practically no second quarter tonnage yet entered.

This condition arises from the pursuit of certain policies by the various producers. In general, the mills that have hitherto catered to railroad demand have been reserving capacity for the railroads when they are again joined to their owners. Few institutions have been the subject of so much idle talk in the past few years as the railroads of the United States. It is almost everybody's avocation to talk about railroads without previously seeking information, and the talk in some quarters about the railroad companies being unable to place orders involving steel when they regain possession of their lines March 1, on account of the rolling space having been pre-empted by other buyers, has this characteristic. The steel mills have experienced no difficulty whatever in seeing that it is their duty not to leave their former great customer in the lurch when he is restored to the position of being able to offer orders. Railroad business will be taken care of, and at March 21 prices.

In the case of the Steel Corporation a restricted sales policy has been necessary not only for self-protection but for the protection of regular customers, to whom the Steel Corporation purposes furnishing as much steel in the future as in the past, and at March 21 prices. Freely open order books on the part of the Steel Corporation in the past three months would have resulted in its being swamped with orders from all quarters. Then, as to the independents who have adhered nominally to March 21 prices, there has been a hope, probably diminished by now, that the Steel Corporation would advance its prices, and advantage of the advance could then be taken. Some independents have sold scarcely anything of late, and are operating for the present quarter on business held over from 1919 on account of the strike. Other independents, who have advanced prices, have been unable to sell except for early deliveries. Taking the steel industry as a whole, practically all the first quarter output is sold even if the output attains the limit of the most sanguine expectations, but not more than about half the second quarter output, at an outside estimate, is sold. Many reservations or promises, however, have been made.

Mill Operations

January opened with steel mills operating at about 80 per cent of capacity, or at the rate of about 40,000,000 gross tons of ingots, or 30,000,000 gross tons of finished rolled steel, a year. Everything is in favor of the rate of operation increasing sharply and no valid reason can be assigned for a prediction that production will be at less than 90 per cent of capacity in March. The discomfort of steel consumers has been so enjoyable to some steel mills, not the majority in point of tonnage capacity by any means, that prospects of better operation have not been regarded with the satisfaction usually obtaining in connection with such an outlook. The philosophy in some quarters appears to have been that it would be enterprising to jack up prices on account of scarcity produced by light operation and then reap the extra profits accruing from full output and a correspondingly lowered cost of production. The United States Steel Corporation's policy in combating this philosophy has been wise and beneficent.

Ferro-Alloys

Domestic producers of ferromanganese have made another $10 a ton advance, and some have gone another $10, making present quotations $140@$150, delivered, and on 76 to 80 per cent alloy instead of the former 78 to 82 per cent. English is now held at $140, c.i.f., though some sales were made recently at $125. Spiegeleisen has continued to stiffen, being now quotable at $45, furnace, for spot and $45@$50 for futures.

Electrolytic ferrosilicon is easy, consumers being apparently well covered, with quotations at $85@$90 for 50 per cent and $140 for 75 per cent, delivered Pittsburgh, valleys and Cleveland. Bessemer ferrosilicon remains at $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, f.o.b. Jackson, Ohio.

The Chemical Market

New York, January 9, 1920.

The heavy chemical market during the past week has remained firm in price, with little actual trading. Consumers seem to be averse to stocking up beyond immediate need, and at present there is a general scarcity in all lines of material in second hands. *Cream of tartar* has been in fair demand in small lots and is quoted at 56@60c. per lb. *Borax* continues firm in price since the jump of 1c., and is now being sold at 8½@9c. per lb. *Roll brimstone sulphur* has been active and came up from $2.95 to $3.20 per 100

lb., while *sulphur sublimed flour* jumped from $3.10 to $3.35. Inquiries on this item are both foreign and domestic. *Epsom salts* has been flurrying and is selling at $2.15 per 100 lb., against a low mark of $2 for last week. The price on *sodium bichromate* at present is 19c. per lb., but owing to the rather heavy demand and small supply the market remains uncertain. Demand continues strong on *caustic soda* and the present supply is reduced to a minimum, while the quotation remains $4.10@$4.35 per 100 lb. A sale has been recorded as high as $4.40, but the Association price is still fixed at $4.25. *Barium chloride* still holds at $85@$90 per ton, while *bromine* advanced from 65@75c. per lb. of last week to 90@95c. There has been considerable inquiry on *iodine resublimed* at $4.10@$4.30 per lb. lately. All quotations on *alcohol* remain nominal and until after Jan. 16 this item will be uncertain both in supply and demand. There is some spot denatured and methyl to be had in small lots but at prices different from those quoted. *Formaldehyde* has a nominal quotation of 20@45c. per lb., due to scarcity. The solution of the alcohol situation would place this item on a firm footing.

Coal-Tar Products.—Demand continues brisk, with most sales being made on forward delivery. Supplies still lag behind and the excessive demand by the automobile trade has not helped the situation. There is a scarcity of *crude solvent naphtha.* The present quotation is 19@24c. per gal. *Dimethylaniline* remains firm at 90c.@$1 per lb., with heavy inquiry. *Pyridine* at $2@$2.50 per gal. and *resorcin* at $3.75@$4.50 per lb., are practically unobtainable at present. *Paranitrotoluol* remains firm at $1.35@$1.50 per lb. and *toluol* is quoted at 29@32c. per gal.

Waxes have been quiet with no change in prices, buying being confined to small orders. *Paraffines* still lag behind demand and all orders are being made for future delivery. Foreign interest in the paraffines has not let up greatly.

Crude turpentine, sp.gr. 0.900-0.970 jumped from $1 to $1.30 per gal. The entrance of the varnish industry as buyer of flotation oil has cramped this market, but the mining industry is still receiving first choice in orders filled.

Naval Stores

The past week has been classified by one who has been engaged in this industry a number of years as "the busiest week in his experience." Although an individual opinion, it is nevertheless an indication of the steadily increasing activity among the naval stores. Prices seem firm for the time being at least and buyers are not scarce, the only thing to be desired being a settling back to normal conditions among the Southern laborers. There is scarcity of some grades of *rosin,* noticeably the D-H grades, quoted at $17.55@$18.25 per 280 lb. I-K are to be had in spot quantities at $19.75@$22 per 280 lb., against $23 as a high mark for last week.

Turpentine has been rising steadily, and although the demand has not been great, the present quotation is $1.76 per gal. It is predicted by some that $2 will be reached before a break will occur. The supply has improved greatly during the past week. A reason advanced for the high price is the condition of the London market, where the price has already reached $2. There is no available spot to be had in England.

Linseed oil is coming back to normal, the current price being $1.77 per gal. For the past few days this item has been resting after the sudden rise. The jump was counteracted by a drop in both domestic and Argentine flaxseed, but with the activity anticipated by the paint industry and the increased construction work, the future looks bright for this market. The activity in price on *soya bean oil* has been accounted for principally by speculation. Many contracts were written last July for January delivery which suddenly increased the demand on this oil. Sellers had been holding off in the hope of easier prices and now to prevent trouble have been buying in large quantities to fill these contracts. The present quotations are, *soya bean Manchurian,* 19@20c. per lb. and 17¾@18c. tank cars f.o.b. Pacific coast.

Crude rubber has been easier, owing to the fact that manufacturers have not completed their inventories. *Para-upriver, fine,* dropped to 48@50c. per lb., against 50@51c. of last week. *Plantation-first latex crepe* came down from 54½c. to 53½c. per lb.

Ores and Semi-Finished Products

The *ores* and *semi-finished products* continue firm, with practically no new business in *molybdenum. Tungsten* was active on inquiry, but there has been nothing of importance outside of that. The quotation at present is $7.50@$10 per ton for *wolframite. Petroleum coke* is quoted at $14 a ton and the Government prices on foundry and furnace grades still prevail. The transportation difficulties have not been relieved by the cold weather, which has further added to the car shortage, and the freezing over of the Monongahela has shut off another outlet. Production is from 30 to 60 days behind and the holiday season still further curtailed output. Added to this the coke makers have shown a dislike to ending the vacation.

Among the miscellaneous materials *barytes* still continues active at $35@$40 per ton, and there is no immediate relief in sight. Manufacturers of this item will not quote beyond a month, so that a quotation may be changed to meet new circumstances which are constantly arising. *Fuller's earth* is practically unobtainable at present and the nominal quotation of $25@$30 per ton domestic still holds.

St. Louis, January 6, 1920.

Good demand for certain of the heavy chemicals, with the exception of sulphuric and muriatic acids, is reported by local works. There is a feeling of firmness about the market that it lacked a short time before the beginning of the year, and while there have been no appreciable price advances, producers look for the present level to hold good for some time.

Approximately the same amount of contract business was consummated at the beginning of the quarter, and a number of concerns that had been buying on a hand-to-mouth basis since the coal strike changed their tactics and made long-term contracts, undoubtedly on the assumption that prices have dropped as low as they will go. There is still a fair amount of spot business, enough to keep prices up.

Sulphuric Acid.—The demand for sulphuric has never gotten back to normal since the coal strike, though several spasmodic attempts have been made to hold it up. The demand is growing slowly, nevertheless, and producers look for it to become normal again by the end of the month. Winter falling-off in drilling operations in several Texas and Louisiana oil fields and the consequent lessened demand for "torpedoes" have had their effect. Fertilizer manufacturers are still taking a large part of the output, on contract this time instead of spot buying. The 60 degree grade is quoted at from $12@$14 a ton, according to quantity, a slight falling off in price on the larger purchases; 66 degree is quoted at $18 a ton. Oleum is quoted at $25 a ton and is in slightly better demand than the two other grades.

Muriatic Acid.—There is a fair movement in this line, though not so good as that of a month ago. Practically only contract business is being done in it at present, though there are a few inquiries. The price remains at $22 a ton for the 18 degree grade.

Sodium Sulphate.—A lessened movement in this branch of the market is reported, though there is enough spot buying to keep the price up, one sale being reported at $20.50 a ton, though most of the sales were made at $19.50@$20.

Sodium Bisulphate.—Just as with the sulphate, there is only a fair movement in this department, some deals having been made at as low as $2.50 a ton, and others at $3 a ton, a falling off of 20 per cent in the last six weeks.

Zinc Chloride.—There is practically no demand for this chemical at all, due to the fact that the present is an off season. The quotation at present for 38 Bé. is 10@10.5c. per lb., but producers look for this price to rise soon.

Zinc Oxide.—Demand continues good, with prices firm. Quotations are: Lead free, 9@9¼c. per lb.; 5 per cent leaded, 8½@8¾c.; 20 per cent leaded, 8@8¼c.; 35 per cent leaded, 7¾@8c.

*Alcohol, denatured, 188 proof	gal.	–	.80 – .82
*Alcohol, denatured, 190 proof	gal.	–	.76 – .78
Alum, ammonia lump	lb.	– .04½	.04½ – .04¾
Alum, potash lump	lb.	.08 – .08¾	.09 – .09½
Alum, chrome lump	lb.	.15 – .16	.18 – .20
Aluminum sulphate, commercial	lb.	.01½ – .02	.02½ – .02½
Aluminum sulphate, iron free	lb.	.02½ – .03	.03½ – .03½
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.08¼ –	.09½ – .10
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	–	.30 – .33
Ammonium carbonate, powder	lb.	.13 – .16½	.17 – .17½
Ammonium chloride, granular (white sal ammoniac)	lb.	.12½ – .14	.13½ – .17½
Ammonium chloride, granular (gray sal ammoniac)	lb.	.12 – .12½	.13 – .13½
Ammonium nitrate	lb.	.22 –	–
Ammonium sulphate	lb.	.05 –	.06 –
Amylacetate	gal.	–	3.65 – 3.75
Arsenic, oxide, lumps (white arsenic)	lb.	–	.10½ – .11
Arsenic, sulphide, powdered (red arsenic)	lb.	–	–
Barium chloride	ton	85.00 – 90.00	100.00 – 110.00
Barium dioxide (peroxide)	lb.	.22 –	.24 –
Barium nitrate	lb.	.09½ – .10½	.11 – .12
Barium sulphate (precip.) (blanc fixe)	lb.	.03 – .03½	.03½ – .04
Bleaching powder (see calcium hypochlorite)		–	–
Blue vitriol (see copper sulphate)		–	–
Borax (see sodium borate)		–	–
Brimstone (see sulphur, roll)		–	–
Bromine	lb.	.90 – .95	–
Calcium acetate	cwt.	2.00 – 2.05	2.10 –
Calcium carbide	lb.	–	.04½ – .05
Calcium chloride, fused, lump	ton	20.00 – 25.00	30.00 – 40.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02½
Calcium hypochlorite (bleaching powder)	cwt.	–	2.50 – 3.75
Calcium peroxide	lb.	–	1.50 – 1.70
Calcium phosphate, monobasic	lb.	–	.75 – .80
Calcium sulphate, pure	lb.	–	.25 – .30
Carbon bisulphide	lb.	.05½ –	.06 – .09
Carbon tetrachloride, drums	lb.	.10¾ – .11	.12 – .15½
Carbonyl chloride (phosgene)	lb.	–	.75 –
Caustic potash (see potassium hydroxide)		–	–
Caustic soda (see sodium hydroxide)		–	–
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.08 –
Cobalt oxide	lb.	–	1.50 – 1.55
Copperas (see iron sulphate)		–	–
Copper carbonate, green precipitate	lb.	–	.28 – .31
Copper cyanide	lb.	–	.65 – .70
Copper sulphate, crystals	lb.	.07¼ – .08¾	.09 – .09½
Cream of tartar (see potassium bitartrate)		–	–
Epsom salt (see magnesium sulphate)		–	2.15 – 2.20
Formaldehyde, 40 per cent	lb.	–	.20 – .45
Glauber's salt (see sodium sulphate)		–	–
Glycerine	lb.	–	.24½ – .26
Iodine, resublimed	lb.	–	4.10 – 4.30
Iron oxide, red	lb.	–	.03 – .20
Iron sulphate (copperas)	cwt.	1.00 –	1.20 – 1.75
Lead acetate, normal	lb.	–	.20 – .23
Lead arsenate (paste)	lb.	–	.13 – .17
Lead nitrate, crystals	lb.	–	.30 – .35
Litharge	lb.	–	.09½ – .10½
Lithium carbonate	lb.	–	1.50 –
Magnesium carbonate, technical	lb.	–	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	2.15 – 2.63	2.75 – 3.00
Magnesium sulphate, commercial	100 lb.	1.75 –	2.00 – 2.50
Nickel salt, double	lb.	.14 –	.15 –
Nickel salt, single	lb.	.12 –	.15 – .16
Phosgene (see carbonyl chloride)		–	–
Phosphorus, red	lb.	–	.75 – .90
Phosphorus, yellow	lb.	–	.35 – .37
Potassium bichromate	lb.	.28 – .33	.34 – .35
Potassium bitartrate (cream of Tartar)	lb.	–	.56 – .60
Potassium bromide, granular	lb.	–	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.25 –	.30 –
Potassium chlorate, crystals	lb.	.16 – .20	.21 –
Potassium cyanide, 98-99 per cent	lb.	nominal	
Potassium hydroxide (caustic potash)	lb.	.28 – .32	.35 – .42
Potassium iodide	lb.	–	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 –
Potassium permanganate	lb.	–	.65 – .95
Potassium prussiate, red	lb.	–	1.10 – 1.20
Potassium prussiate, yellow	lb.	–	$0.40 – $0.70
Potassium sulphate	ton	$225.00 –	–
Rochelle salt (see sodium potas. tartrate)		–	–
Sal ammoniac (see ammonium chloride)		–	–
Sal soda (see sodium carbonate)		–	–
Salt cake (sodium sulphate)	ton	15.00 – 21.00	–
Silver cyanide	oz.	–	1.25 –
Silver nitrate	oz.	–	.81½ – .82½
Soda ash, light	100 lb.	2.05 –	2.25 –
Soda ash, dense	100 lb.	2.25 – 2.35	2.50 – 2.75
Sodium acetate	lb.	.05½ – .06½	.07 – .08
Sodium bicarbonate	100 lb.	2.35 –	2.75 – 3.00
Sodium bichromate	lb.	.18 – .19	.22 – .25
Sodium bisulphate (nitre cake)	ton	3.00 – 8.00	10.00 –
Sodium bisulphite	cwt.	1.80 – 1.90	2.00 – 2.10
Sodium borate (borax)	lb.	– .08	.08½ – .09
Sodium carbonate (sal soda)	100 lb.	1.40 – 1.55	1.50 – 1.75
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.30 –	.31 – .34
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	–	4.10 – 4.35
Sodium hyposulphite	lb.	–	.03½ – .04
Sodium molybdate	lb.	2.50 –	3.25 –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.15 – .17	– .18
Sodium peroxide, powdered	lb.	–	.30 – .32
Sodium phosphate, dibasic	lb.	.03½ – .04	.04½ – .05
Sodium potassium tartrate (Rochelle salt)	lb.	–	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .39	.24 – .40
Sodium silicate, solution (40 deg.)	lb.	.01¼ – .02	.02 – .02½
Sodium silicate, solution (60 deg.)	lb.	.02¼ – .03	.03½ – .04½
Sodium sulphate, crystals (Glauber's salts)	cwt.	1.15 – 1.25	1.50 – 2.00
Sodium sulphide, crystal, 60-62 per cent. (conc.)	lb.	–	.05 – .06
Sodium sulphite, crystals	lb.	.03½ –	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05½ –	.06 –
Sulphur, crude	ton	22.00 –	–
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½ –	.46 – .50
Tin oxide	lb.	.43 –	.60 –
Zinc carbonate, precipitate	lb.	–	.20 –
Zinc chloride, gran.	lb.	.12½ –	.13½ – .15
Zinc cyanide	lb.	.49 –	.50 –
Zinc dust	lb.	.09 – .11	.11 – .14
Zinc oxide, dry American	lb.	–	.09½ – .12
Zinc sulphate	lb.	.03½ – .03¾	.04 – .04½

*Nominal quotations.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.50
Alpha naphthylamine	lb.	.34 —	.37
Aniline oil, drums extra	lb.	.34 —	.37
Aniline salts	lb.	.43 —	.48
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	1.75 —	–
Benzidine, base	lb.	1.10 —	–
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.31
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech.	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.52
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech.	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U.S.P., in drums (100 lb.)	lb.	.18 —	–
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.75 —	.80
Cresylic acid, 95-97%, dark, in drums	gal.	.72 —	.75
Cresylic acid, 50%, first quality, drums	gal.	.60 —	–
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	2.25
Dimethylaniline	lb.	.90 —	1.00
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.58 —	.75
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.27 —	.30
Ortho-amidophenol	lb.	3.00 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.90 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-bensol	lb.	.15 —	.18
Paranitraniline	lb.	1.00 —	1.20
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.50 —	4.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.70 —	1.00
Phenol, U.S.P., drums (dest.), (240 lb.)	lb.	12¾ —	.19
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.45 —	.60
Salicylic acid, U.S.P.	lb.	.45 —	.50
Salol	lb.	.90 —	.95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.22 —	.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30

Toluidine	lb.	$1.70	— $2.50
Toluidine, mixed	lb.	.45	— .55
Toluol, in tank cars	gal.	.28	— .....
Toluol, in drums	gal.	.29	— .32
Xylidine, drums, 100 gal.	lb.	.44	— .50
Xylol, pure, in drums	gal.	.37	— .45
Xylol, pure, in tank cars	gal.	.35	— .....
Xylol, commercial, in drums, 100 gal.	gal.	.37	— .45
Xylol, commercial, in tank cars	gal.	.23	— .27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42	— $0.45
Beeswax, refined, yellow	lb.	.47	— .48
Beeswax, white, pure	lb.	.63	— .68
Carnauba, No. 1	lb.	.80	— .88
Carnauba, No. 2, regular	lb.	.65	— .78
Carnauba, No. 3, North Country	lb.	.43	— .48
Japan	lb.	.18½	— .20
Paraffine waxes, crude match wax(white) 105-110 m.p.	lb.	.06	— .07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.....	— .06½
Paraffine waxes, refined, 118-120 m.p.	lb.	.....	— .09¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.09¾	— .10½
Paraffine waxes, refined, 133-135 m.p.	lb.	.....	— .12
Paraffine waxes, refined, 135-137 m.p.	lb.	.....	— .13
Stearic acid, single pressed	lb.	.23	— .26
Stearic acid, double pressed	lb.	.28	— .29
Stearic acid, triple pressed	lb.	.32	— .33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940	gal.	$1.30
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp.gr., 0.900-0.970	gal.	1.30
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.49

Naval Stores

The following prices are f.o.b., New York, for carload lots:

Rosin B-D, bbl.	280 lb.	$17.00	—$17.50
Rosin E-I	280 lb.	17.85	— 18.40
Rosin K-N	280 lb.	19.75	— 22.50
Rosin W. G.-W. W.	280 lb.	22.50	— 24.25
Wood rosin, bbl.	280 lb.	17.00	— 17.50
Spirits of turpentine	gal.	1.76	— 1.85
Wood turpentine, steam dist.	gal.	....	— 1.70
Wood turpentine, dest. dist.	gal.	1.64	— ....
Pine tar pitch, bbl.	200 lb.	8.25	— 8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50	— 14.75
Retort tar, bbl (500 lb.)	bbl.	15.00	— 15.25
Rosin oil, first run	gal.	....	— .91
Rosin oil, second run	gal.	.93	— .94
Rosin oil, third run	gal.	1.10	— 1.12
Rosin oil, fourth run	gal.	....	— 1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naptha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.48½	— $0.50
Upriver coarse	lb.	.35	— .37
Upriver caucho ball	lb.	.34½	— .36
Plantation—First latex crepe	lb.	.53½	— .54½
Ribbed smoked sheets	lb.	.53½	— ....
Brown crepe, thin, clean	lb.	.48	.48½
Amber crepe No. 1	lb.	.53	— ....

Oils

VEGETABLE

The following prices are f.o.b., New York, for carload lots:

Castor oil, No. 3, in bbls.	lb.	$0.18	— $0.19
Castor oil, AA, in bbls.	lb.	.21	— .23
China wood oil, in bbls.	lb.	.23¾	— .24½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.19½	— .20
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½	— .23
Corn oil, crude, in bbls.	lb.	.19	— .22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19	— .20
Cottonseed oil, summer yellow	lb.	.22	— .27
Cottonseed oil, winter yellow	lb.	.24½	— .25½
Linseed oil, raw, car lots	gal.	1.77	— 1.87
Linseed oil, raw, tank cars	gal.	1.70	— 1.80
Linseed oil, boiled, car lots	gal.	1.75	— 1.80
Olive oil, commercial	gal.	2.50	— 2.60
Palm, Lagos	lb.	.16	— .17½
Palm, bright red	lb.	.16½	— .17½
Palm, Niger	lb.	.16	— .17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½	— .23½
Peanut oil, refined, in bbls.	lb.	.27	— .28
Rapeseed oil, refined in bbls.	gal.	1.45	— 1.65
Rapeseed oil, blown, in bbls.	gal.	1.60	— 1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19	— .20
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17¾	— .18

FISH

Winter pressed Menhaden	gal.	$1.20	— ....
Yellow bleached Menhaden	gal.	1.23	— ....
White bleached Menhaden	gal.	1.25	— ....
Blown Menhaden	gal.	1.26	— ....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00	—$40.00
Barytes, off color	ton	20.00	— 25.00
Blanc fixe, dry	lb.	.03½	— .04½
Blanc fixe, pulp	ton	30.00	— 50.00
Casein	lb.	.16	— .18
Chalk, English, extra light	lb.	.05	— .07
Chalk, English, light	lb.	$ .04½	— $ .06
Chalk, English, dense	lb.	.04	— .05
China clay (Kaolin), imported, lump	ton	25.00	— 35.00
China clay (Kaolin), imported, powdered	ton	30.00	— 60.00
China clay (Kaolin), domestic, lump	ton	10.00	— 20.00
China clay (Kaolin), domestic, powdered	ton	25.00	— 40.00
Feldspar	ton	13.50	— 18.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30.00	— 35.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35.00	— 45.00
Fuller's earth, domestic, powdered	ton	25.00	— 30.00
Fuller's earth, imported, powdered	ton	35.00	— 40.00
Pumice stone, imported	lb.	.03	— .06
Pumice stone, domestic	lb.	.02½	— ....
Shellac, TN	lb.	1.10	— 1.15
Shellac, D. C.	lb.	....	— ....
Shellac, V. S. O.	lb.	....	— ....
Shellac, Diamond I.	lb.	....	— ....
Shellac, orange, fine	lb.	1.25	— ....
Shellac, orange, superfine	lb.	1.20	— 1.30
Shellac, A. C. garnet	lb.	1.10	— ....
Shellac, bleached, bone dry	lb.	1.35	— ....
Shellac, bleached, fresh ground	lb.	1.10	— 1.15
Soapstone	ton	15.00	— 25.00
Talc, domestic	ton	16.00	— 60.00
Talc, imported	ton	60.00	— 70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	80-90 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	35-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	30-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-90 at Chester, Penn.
Silica brick	1,000	41-45 at Mt. Union, Penn.

Ferro-Alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00	—$250.00
Ferro-chrome per lb. of Cr contained, 6-8% carbon	lb.	.20	— .40
Ferro-chrome per lb. of Cr contained, 2-4% carbon	lb.	.21	— .50
Ferro-manganese, 70-80% Mn	gross ton	140.00	— 150.00
Spiegeleisen, 16-20% Mn	gross ton	40.00	— 50.00
Ferro-molybdenum, per lb. of Mo	lb.	3.00	— 3.50
Ferro-silicon, 50%	gross ton	85.00	— 95.00
Ferro-silicon, 75%	gross ton	150.00	— 175.00
Ferro-silicon, 10-15%	gross ton	45.00	— 60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1.25	— 1.40
Ferro-uranium, 35-50%, of U	lb.	7.00	— ....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	5.50	— 7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, C_2, O_3	unit	$0.60	— $0.85
Chrome ore, 48% and over	unit	1.00	— 1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00	— 7.50
*Coke, furnace, f.o.b. ovens	net ton	6.00	— 6.50
Petroleum coke, refinery, Atlantic seaboard	net ton	.....	— 14.00

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.80
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	16.00
Yellow pine, 3x4 to 8x8, 20 ft. and under	M.	48.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago	M.	50.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis	M.	40.00
Roofings, tar felt (14 lb. per 100 sq. ft.)	ton	70.00
Roofings, tar pitch (in 400-lb. bbl.) carlots	ton	21.00
Roofings, asphalt pitch carlots	ton	34.00
Roofings, asphalt felt carlots	ton	63.00
Roofings, slate-surfaced, per roll of 108 sq. ft. carlots		2.25
Roofings, slate-finished shingles, 100 sq. ft. carlots		6.00
Linseed oil, raw in barrels	gal.	1.75
Linseed oil, 5 gal. cans	gal.	1.90
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.15½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13½
White lead, dry and in oil ,5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

EL MONTE — The city voted $55,000 bonds to construct a sewerage system and septic tank. Olmsted & Gillelen, 1112 Hollingsworth Bldg., Los Angeles, engrs.

LOS ANGELES — The Mathews Paint Co., 219 South Los Angeles St., has awarded the contract for the construction of a 2-story, 99x99-ft. paint factory on San Fernando Rd., to J. V. McNiel, 736 H. W. Hellman Bldg. Estimated cost, $40,000.

MODESTO—The city voted $30,000 bonds to construct a sewage disposal plant. G. H. Freitas, city engr.

STOCKTON—The Natl. Paper Products Co. is preparing plans for a fireproof addition to its mill. Estimated cost, $1,000,000.

Illinois

CHICAGO—The Chicago Coated Board Co., 11 South La Salle St., plans to build a plant at Cottage Grove Ave. and 138th St. Estimated cost, $3,000,000.

CHICAGO—R. G. Pierce, archt, 10 South La Salle St., will soon receive bids for the construction of a 1-story, 75x80-ft. factory at East 94th St. and Commercial Ave., for the United States Graphite Co., 80 East Jackson Blvd. Estimated cost, $25,000. N. Ronneberg, 10 South La Salle St., engr.

Iowa

DANVILLE—The Sugar Creek Creamery Co. has awarded the contract for the construction of a 2-story addition to its plant, to the Clark Construction Co., Danville. Estimated cost, $50,000.

CORYDON—The city will soon award the contract for the construction of a filter and settling basin, also for furnishing filter house equipment, etc. A. T. Gallagher, city clk. M. G. Hall, civil and sanitary engineer, Centerville, engr.

Maryland

LAMCELLE (Cumberland P. O.)—The American Cellulose & Chemical Mfg. Co. plans to build a large addition to its plant. Guy Leonard, genl. mgr.

CURTIS BAY (Baltimore P. O.)—The Union Acid Wks. will be incorporated to construct a plant to cost $1,000,000; same to have daily capacity of 200 tons of sulphuric acid. A site of 7 acres has been purchased adjoining the plant of the Standard Acid Wks. Address George A. Whiting, Continental Bldg., Baltimore.

Michigan

DETROIT—The Detroit Graphite Co., 12th St., engaged E. R. Dunlap, archt., 209 Hammond Bldg., to prepare plans for the construction of a 2-story paint factory on Linsdale Ave. Estimated cost, $30,000.

Mississippi

BROOKHAVEN — The Mayor and the Board of Aldermen will receive bids until Jan. 20 for the construction of a sewerage system, including a disposal plant. Chester Byrne, city clk., M. L. Culley, Jackson, engr.

New York

BROOKLYN—Knoor Bros., 1116 Wyckoff Ave., will build a 1-story, 80x90-ft. brass foundry on Cooper Ave., near the tracks of the Long Island R.R. Estimated cost, $30,000. Work will be done by day labor.

COLLEGE POINT (Flushing P. O.)—J. B. Kleinert Rubber Co., 725 Broadway, New York City, will soon award the contract for the construction of a 4-story factory. Estimated cost, $150,000. R. G. Cory, 39 Cortlandt St., New York City, archt. and engr.

New Jersey

DOVER (Picatinny)—A. Niles, commanding officer, Dover Arsenal, will soon receive bids for remodeling and reconstructing certain buildings here for experimental plant for chemicals for Ordnance Bureau. Estimated cost, $4,000,000 and $5,000,000.

TRENTON—The Ajax Rubber Co., Breunig Ave., plans to construct a 3-story, 60x350-ft. rubber plant. Estimated cost, $39,000. H. M. Baer, 101 Park Ave., New York City, archt. and engr.

Ohio

CLEVELAND—The Acorn Refining Co., 8001 Franklin Ave., will soon award the contract for the construction of a 4-story, 40x105-ft. factory. Estimated cost, $60,000. E. M. Katz, pres.

CLEVELAND—The Paramount Brass Co., 1391 East 33rd St., has awarded the contract for the construction of a 1-story, 40x120-ft. brass factory at 1391 East 33rd St., to H. G. Slatmyer, 203 Lakeside Ave. Estimated cost, $10,000.

Oklahoma

LAWTON—The Lawton Star Refinery, recently organized, plans to build an oil refinery on a 15-acre tract just north of the Fair Grounds. Estimated cost, $100,000. F. A. Parkinson, pres., G. S. Hallman, mgr.

Pennsylvania

WILKES-BARRE — The Diamond Drug Co. is preparing plans for the construction of a 3-story, 22x180-ft. drug factory on Northhampton St. Estimated cost, $170,000.

Tennessee

MEMPHIS—The University of Tennessee, College of Medicine, 718 Union, plans to build a laboratory on Madison Ave., for the City Hospital, which it controls. Estimated cost, $100,000. H. A. Morgan, Nashville, pres.

Wisconsin

SHEBOYGAN—The Porcelain Enameling Association plans to remodel and rebuild part of the 4-story 60x150-ft. factory on Lake Shore Rd., recently destroyed by fire. Estimated cost, $20,000. Address W. J. Vollroth, 82 West 6th St.

Ontario

OWEN SOUND—The Bd. Educ. plans to construct a 13-story collegiate institute. Ratepayers voted on $180,000 bylaw to raise money for same. Chemical and physical laboratory equipment will be installed in same.

SARNIA—The Lake Huron Steel Corp. has purchased an 1,100-acre site along the St. Clair River and plans to construct a steel plant on same, to have a capacity of 100,000 tons of alloy steel annually. Estimated cost, $10,000,000. S. A. Howard, engr.

TORONTO—The Prest-O-Lite Co., Inc., 120 Elm St., has awarded the contract for the construction of a 3-story plant, on Hillcrest Race Course, to Wells & Gray, Confederation Life Bldg. Estimated cost, $400,000.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23-26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9, and 10.

THE AMERICAN ELECTROCHEMICAL SOCIETY, New York Section, will hold a meeting, Jan. 23, on "Cheap Cyanide and Its Disposition."

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16-19.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

Industrial Notes

THE RICHARDSON-PHENIX CO., Milwaukee, Wis., has opened a Birmingham, Ala., office, in charge of James D. Scruggs.

THE BESSEMER LIMESTONE & CEMENT CO., Youngstown, Ohio, announces that it has taken over all the properties of the Bessemer Limestone Co. and is successor to it.

W. L. SAVELL and J. G. G. FROST, formerly general supt. and chemical supt., respectively, of Metals-Chemical, Welland, Ont., Canada, have opened a consulting office at 732 Frankfort Ave., Cleveland, Ohio, under the firm name of Savell & Frost.

ARTHUR D. LITTLE, INC., which designed, erected and put into operation the plant for the production of rosin, turpentine and pine oil from pine stumps for the National Reduction Corp. at Calvert, Ala., has turned it over to the owners as a going concern. It is of especial interest at this time in view of the demand for the reclamation for agricultural purposes of the cut-over lands of the South. Arthur D. Little, Inc., also announces that its experimental paper mill, which has been busy for some months on demonstrations of the paper-making quality of linters and cotton hull fiber which, during the war, were the chief sources of cellulose for the nitrocellulose used in smokeless powder, is now engaged on the commercial production of the acid-washed filter paper for quantitative chemical analysis formerly imported. Its capacity for this purpose is more than sufficient to meet the entire American demand and to insure the highest possible quality of product. The mill is operating on distilled water.

THE QUIGLEY FURNACE SPECIALTIES CO., New York City, announces that after several years experimenting with alloys and special steels for heat treating, it is putting on the market a complete line of carbonizing pots and annealing boxes for heat treating. These products are made of a special analysis known as Q-steel, designed for maximum resistance to oxidation, coupled with minimum cost per heat-hour of service. In addition to the low priced steel boxes and special castings, the company will market two high-grade alloys for similar work where the operating conditions will make this class of material more economical. The department of heat treatment will be under the management of H. H. Harris.

PERCY SCOTT LEGGATT, of Summerson & Co., Darlington, England, has been investigating the iron and steel possibilities on the coast at Vancouver, B. C., with the view to erecting an electric smelting plant there. Mr. Leggatt claims to have the capital behind him if he can obtain the necessary ore and power concessions. The furnaces would be made by his firm in England and sent to Vancouver knocked down.

A. P. Gillis, on behalf of the TIVANI ELECTRIC STEEL CO., of Belleville, Ont., claims that he has arranged the purchase of a $5,000,000 bond issue for the erection of an electric iron and steel plant of a capacity of 200 tons per day if the citizens of Vancouver will guarantee the interest on the bond issue for a number of years and will guarantee 50,000-hp. continuous service at $10 per hp.-yr.

THE VANCOUVER ENGINEERING WORKS, Vancouver, Canada, is installing an electric furnace for the production of special steels to be used in the construction of machinery that the company manufactures.

THE AMERICAN CONSTITUTIONAL LEAGUE has been organized by influential business men in Milwaukee, for the promotion of Americanization work. This will embrace all forms of education and publicity in favor of Americanism and in opposition to radicalism. Frank R. Bacon, president of the Cutler-Hammer Mfg. Co., Milwaukee, has been elected chairman of the new organization.

THE JARECKI CHEMICAL CO. of Cincinnati, Ohio, is rebuilding its plant, which was partially destroyed by fire last September. The Austin Co. has the contract for rebuilding this plant, the main portion of which is a special electric crane type fertilizer plant, 135 x 540 ft., to be used for acidulating, curing and storing chemical fertilizer and will run approximately $400,000 in cost. Gustav Jarecki is president.

THE INTERSTATE COMMERCE COMMISSION has declared unreasonable the rates on fertilizer from Mobile, Ala., to various stations on the Southern Pacific lines in Louisiana. These rates were attacked in a case brought by the Virginia-Carolina Chemical Co.

THE INTERNATIONAL OXYGEN CO., with main offices at Newark, N. J., is establishing a new branch plant at Toledo, Ohio, to furnish oxygen and hydrogen for all purposes to the numerous manufacturers and industries in that industrial section using either one or both of these gases in their processes. The capacity of the plant will be 3,000,000 cu.ft. of gas per month, the purity of which is said to be 99.5 per cent and higher.

FRANK H. NICKLE, manufacturer of agitator driving yokes, a standard power transmission device for driving agitator or stirrer shafts in open or closed chemical tanks, kettles and other containers, announces the organization of the Nickle Engineering Works, with office and factory at 729 North Niagara St., Saginaw, Mich. The company will install additional machine shop equipment and increase the scope of operations.

LAWRENCE M. BRILE, who has been connected for the last five years with the United Smelting & Aluminum Co., Inc., as vice president and sales manager, severed his connection with that company on Jan. 1, on which date he assumed the presidency of Brile & Ratner, Inc., a New York corporation, formed to engage in the metal and chemical brokerage business. Mr. Brile will take charge of the non-ferrous metal end of the business, while Mr. Ratner will take charge of the chemicals department. Temporarily, the office of Brile & Ratner, Inc., will be located at 115 Broadway, New York City.

THE JERRY JOHNSON 100-TON CYANIDE MILL at Cripple Creek is being dismantled by the Morse Bros. Machinery & Supply Co, of Denver. This mill, erected in 1914 and used but a few months, was completely equipped with Dorr thickeners, agitators and classifiers, Oliver filter, etc. The material is being shipped to Denver for resale.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, announces that the Atlas Machinery & Supply Co. is now handling the sale of the American steam ash conveyor in St. Louis territory. This company has offices at 1416 Syndicate Trust Bldg., St. Louis, Mo., and is a new sales organization in that vicinity headed by William H. Patton, who recently returned to the United States after two years service in the Army.

THE N. P. PRATT LABORATORY, one of the oldest chemical laboratories in the South, has sold its entire analytical department, together with its good will. Its successor will be known as Brogdon-Dumas Laboratories, Inc. The concern will do a general chemical engineering practice, including the making of all kinds of assays and analyses. J. S. Brogdon has conducted a commercial chemical laboratory in Atlanta for the past eleven years. W. C. Dumas, former state chemist of Georgia, more recently chief chemist of the N. P. Pratt Laboratory, has during the past thirteen years at various times been connected with the N. P. Pratt Laboratory. Additional space has been secured adjoining the old laboratory of J. S. Brogdon at 70½ Peachtree St., Atlanta, Ga. The union of these two laboratories makes a most complete chemical equipment.

New Publications

THE SCIENTIFIC AMERICAN PUBLISHING CO., 233 Broadway, New York City, announces that beginning with Jan. 1, 1920, the *Scientific American Supplement* will be changed in form and in period of issue. The new journal will be published on the first of each month, and will be known as the *Scientific American Monthly*.

THE BANKERS TRUST CO., of New York, has just published a brochure, "Financial Status of Belligerents," by Louis Ross Gottlieb, setting forth authoritatively and interestingly the debt, revenue and expenditure, and the note circulation of the principal belligerents in the World War.

THE GEOLOGICAL SURVEY OF GEORGIA has just issued a preliminary report on the oil prospect near Scotland, Telfair Co., Ga., by J. P. D. Hull and L. P. Teas.

THE PORTLAND CEMENT ASSN. is distributing a booklet entitled "Concrete Tanks for Industrial Purposes."

THE THIRD ANNUAL REPORT of the United States Council of National Defense for the fiscal year ended June 30, 1919, has just been issued.

A STUDY OF THE FORMS IN WHICH SULPHUR OCCURS IN COAL. By A. R. Powell and S. W. Parr. Bull. No. 111, Engineering Experiment Station, published by the University of Illinois, Urbana, Ill.

"SECURING BETTER COMBUSTION OF MID-WEST, WESTERN AND SOUTHWESTERN FUELS" is the title of a booklet issued by the Green Engineering Co., East Chicago, Ind., which contains eight articles taken from *Electrical World* and *Power*.

THE SALES MANAGER'S BUREAU of the St. Louis Chamber of Commerce has published a pocket-size trade directory comprising a classified list of manufacturers and jobbers in the district.

THE EXPERIMENT STATION of the Hawaiian Sugar Planters Assn. has issued a bulletin (No. 45), published at Honolulu on "The Paper Making Qualities of Hawaiian Bagasse," by Arthur D. Little, Inc., of Cambridge, Mass. It contains a general survey of the question, a discussion of previous attempts to use bagasse as paper-making material, description of the principal paper-making processes, discussion of the technique involved in handling Hawaiian bagasse with reference to the experimental results obtained, the commercial aspect of making paper in Hawaii from bagasse and the class of product which might be made, estimates of production and costs and tabulation of experimental data. The report followed the successful design and construction of a mill in Hawaii now in operation making a soft paper felt from bagasse which is used as a protection against weeds in the sugar cane fields under the Eckert patents. By this means about 50 to 70 per cent of the labor costs are avoided, and the yield is increased. The sharp, stiff cane sprouts break through the felt, while the soft-topped woods curl up and die.

THE THIRD ANNUAL REPORT of the United States Tariff Commission has just been issued.

"AMERICAN AND INTERNATIONAL LABOR CONDITIONS" is the title of a new booklet which gives a complete report of the proceedings of the Fall National Conference held under the auspices of the Society of Industrial Engineers, Cleveland, Ohio, Oct. 29 to 31, 1919.

ANNUAL REPORT OF THE DIRECTOR, BUREAU OF STANDARDS, to the Secretary of Commerce for the fiscal year ended June 30, 1919, has just been published by the Department of Commerce, Washington, D. C., and is known as Miscellaneous Publication No. 40.

SMELTER TREATMENT RATES. Bull. No. 30, published by the Canada Department of Mines, Ottawa, which is the report of the Committee of Investigation in the matter of tolls charged by the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail, B. C., June, 1919.

Compressed Air Magazine appears in new form and style with the issue for January, 1920. Announcement is made in that issue of the fact that the magazine is entering upon its twenty-fifth year. W. L. Saunders has been editor in chief from the beginning, but now retires to be succeeded by Francis Judson Tietsort as editor and general manager. Other members of the staff are Eugene P. McCrorken, managing editor, formerly assistant editor of *Engineering and Mining Journal*, and Frank Richards as technical editor.

THE FEDERAL BOARD FOR VOCATIONAL EDUCATION has issued its third annual report.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS I: 5 "Silver, Copper, Lead and Zinc in the Central States in 1918," Mines report, by J. P. Dunlop and B. S. Butler (Mineral Resources of the U. S., 1918, Part I), published Oct. 31, 1919; I: 7, "Quicksilver in 1918," by F. L. Ransome, with a supplementary bibliography by Isabel P. Evans (Mineral Resources of the U. S., 1918, Part I), published Oct. 31, 1919; I: 8, "Gold, Silver, Copper and Lead in South Dakota and Wyoming in 1918," Mines report, by Charles W. Henderson (Mineral Resources of the U. S., 1918, Part I), published Nov. 6, 1919; I: 9, "Arsenic, Bismuth, Selenium, and Tellurium in 1918," by James M. Hill (Mineral Resources of the U. S., 1918, Part I), published Nov. 19, 1919; I: 19, "Platinum and Allied Metals in 1918," by James M. Hill (Mineral Resources of the U. S., 1918, Part I), published Dec. 8, 1919; II: 14, "Fluorspar and Cryolite in 1918," by Ernest F. Burchard (Mineral Resources of the U. S., 1918, Part II), published Dec. 9, 1919; II: 17, "Silica in 1918," by Frank J. Katz (Mineral Resources of the U. S., 1918, Part II), published Dec. 4, 1919; I: 23, "Manganese and Manganiferous Ores in 1917," by D. F. Hewett (Mineral Resources of the U. S., 1919, Part I), published Oct. 31, 1919: I: 24, "Gold, Silver, Copper, Lead and Zinc in New Mexico and Texas in 1917," Mines report, by Charles W. Henderson (Mineral Resources of the U. S., 1917, Part I), published Nov. 8, 1919; II: 12, "Gypsum in 1918," by Ralph W. Stone (Mineral Resources of the U. S., 1918, Part II), published Nov. 6, 1919; II: 13, "Sand and Gravel in 1918," by R. W. Stone (Mineral Resources of the U. S., 1918, Part II), published Oct. 31, 1919; II: 15, "Peat in 1918," by C. C. Osbon (Mineral Resources of the U. S., 1918, Part II), published Nov. 24, 1919; II: 35, "Coal in 1917. Part B.: Distribution and Consumption," by C. E. Lesher (Mineral Resources of the U. S., 1917, Part II), published Nov. 18, 1919; Bull. 700, "The Analysis of Silicate and Carbonate Rocks" (A revised and enlarged edition of Bull. 422), by W. F. Hillebrand.

NEW BUREAU OF STANDARDS PUBLICATIONS: Scientific Paper 346, "Oxygen Content by the Ledebur Method of Acid Bessemer Steels Deoxidized in Various Ways," by J. R. Cain and Earl Pettijohn, issued Nov. 11, 1919; Sci. Paper 347, "Heat Treatment of Duralumin," by P. D. Merica, R. G. Waltenberg and H. Scott, issued Nov. 15, 1919; Sci. Paper 350, "Equilibrium Conditions in the System Carbon, Iron Oxide and Hydrogen in Relation to the Ledebur Method for Determining Oxygen in Steel," by J. R. Cain and Leon Adler, issued Nov. 10, 1919; Tech. Paper 137, "Coking of Illinois Coal in Koppers Type Oven," by R. S. McBride and W. A. Selvig, issued Nov. 17, 1919; Tech. Paper 141, "Electrolytic Resistance Method for Determining Carbon in Steel," by J. R. Cain and L. C. Maxwell, issued Dec. 6, 1919; Tech. Paper 146, "Cadmium Electrode for Storage Battery Testing," by H. D. Holler and J. M. Braham, issued Dec. 12, 1919; Ninth annual report by the director of the Bureau of Mines to the Secretary of the Interior, for the fiscal year ended June 30, 1919.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 162, "Removal of the Lighter Hydrocarbons From Petroleum by Continuous Distillation," by J. M. Wadsworth; Bull. 181, "Abstracts of Current Decisions on Mines and Mining, Reported From January to May, 1919," by J. W. Thompson; Tech. Paper 211, "Approximate Quantitative Microscopy of Pulverized Ores, Including the Use of the Camera Lucida," by Will H. Coghill and J. P. Bonardi; Tech. Paper 234, "Sensitiveness of Explosives to Frictional Impact," by S. P. Howell.

Manufacturers' Catalogs

THE LAW METALLIC PACKING CO., INC., New York City, has issued a pamphlet on "Law Metallic Packing."

WILLIAM R. PERRIN & CO., Chicago, Ill., calls attention to a booklet illustrating and describing filter presses for beet or cane sugar refineries.

THE FRANKLIN MANUFACTURING CO., Franklin, Pa., is distributing Catalog FC 7-19, on heat insulations, covering 78 pages. Less than one-half of this pamphlet deals with the Franklin Mfg. Co. products specifically; the rest constitutes a complete and useful handbook on the subject of heat insulation. Complete tables, diagrams, instructions and illustrative examples are given so that the proper kind and correct thickness of pipe covering can be determined for any set of conditions.

THE SCHUTTE & KOERTING CO. has issued a pamphlet recently entitled "Our Part in the War." Copies will gladly be sent to those applying.

THE UNITED STATES CONDITIONING AND TESTING CO., New York, has issued a pamphlet entitled "Tests and Analyses," which includes a price list of tests and analyses on dyestuffs, oils, soaps, rubber goods, paper, silk, cotton, wool, and fibers. The company maintains a chemical department which is prepared to analyze soaps, oils, raw materials, dyestuffs, chemicals, etc.

THE ELECTRIC FURNACE ASSN., Niagara Falls, N. Y., has issued a booklet on "Steel."

THE BACHARACH INDUSTRIAL INSTRUMENT CO., Pittsburgh, Pa., has recently issued two pamphlets. Pamphlet P summarizes the extended experience in the field of Pitot tubes and orifices; pamphlet F describes a new pressure-volume indicator, suitable for permanent installations or testing purposes.

THE DENVER FIRE CLAY CO., Denver, Col., calls attention to its attractive catalog on Melting Furnaces, known as Bull. 450, which illustrates and describes tilting furnaces, gas-fired furnaces, a motor blower, a combination burner, an oil furnace, etc.

GUYTON & CUMFER MFG. CO., of 4451 Fillmore St., Chicago, has issued Bulletin No. 101 covering steam-jacketed pumps and steam-jacketed pipe-fittings. This bulletin contains various illustrations of the pumps and accessories and tables with the necessary dimensions for design and erection.

Senate Passes The Water-Power Bill

BY A vote of substantially three to one the Senate passed on January 9 a bill for the development of water power in the United States. While the bill is not identical with that passed by the House last summer, there is agreement on essential points and there should be little difficulty in settling the difference in conference. The Senate bill provides for a Federal water-power commission consisting of the Secretaries of War, Agriculture and the Interior, which is authorized to license the development and operation of projects for a period of fifty years. At the expiration of licenses the Government has the right to take over the plant, issue a new license or permit continued operation under the old license. Licensees are to be required to pay an annual charge not exceeding twenty-five cents per developed horsepower, to reimburse the Government for the cost of administration and use and occupation of public lands necessary for the development of the project covered by the license.

One hesitates to grow too optimistic over this prospect of early enactment of water-power legislation. The subject has been debated for so many years that one emergency after another has found the country impotent to realize on its sources. Responsibility for the delay is being realized in the Senate, where Senator Williams declared recently during debate on the water-power bill that "the people of this country are gradually rising to the point where they demand abolition of the Senate for failing to function." But the Senate has now acted and it seems unlikely that much more delay will ensue, at least not more than is inherent in reaching agreement in conference. The national importance of the measure should spur the conference committee to early action.

More Power To the Chemist

ONE cannot read the remarks of OTTO EISENSCHIML before the Chicago Section of the American Chemical Society at the December 19 meeting under the subject "The Business Side of Chemistry," published in our last issue, without feeling that he has struck the keynote of greater success to the chemist and engineer in their dealings with the business world. The conditions under which business is done make every man engaged therein a salesman whether he desires it or not. Every word he utters in business connections, every move he makes, affects the sale of his personality with other people, whether it be conscious or unconscious. As the very foundation of business is the production of values, a man cannot be successful therein unless he is cognizant of the quantities and prices involved.

The chemical profession divides itself roughly into three classes: namely, the research chemist, who has to do with the production of values through new processes; the chemical engineer, who is interested in the installation of the plant for the successful production of the chemical, and the operator of chemical works, who has to do with the production and sale of chemicals when the plant is installed.

The research chemist may better his lot by demonstrating to his principals the value on a commercial basis of his discoveries. The chemical engineer, being by nature a business man, will collect deserved remuneration for the successful completion of the new plant. The operating chemist should be compensated for economies of operation effected or sales contracts consummated.

As Mr. EISENSCHIML stated, it is only a matter of business, which, in turn, is "common sense."

Wood Alcohol As a Beverage

THE recent fatalities in New England and New York resulting from the sale and consumption of certain intoxicating liquors containing wood alcohol should stimulate every chemist to use his individual influence in spreading information regarding the poisonous nature of this compound. To the chemist "alcohol" is a generic term and, since he is familiar with a large number of compounds belonging to this same class, the term is not necessarily associated in his mind with ethyl alcohol for beverage use.

Unfortunately, the public seems to be able to distinguish only two kinds of alcohol: denatured alcohol containing some evil smelling or ill tasting compound which obviously renders it unfit for human consumption, and alcohol which can be used in beverages. Wood alcohol, not being specifically designated as denatured (although, of course, it is used as a denaturing agent in many cases), is undoubtedly considered by many as belonging to the second class. The fact that containers of wood alcohol bear a label "poison" has even been explained by certain unscrupulous dealers as a ruse to prevent the Government from placing an internal revenue tax upon the contents. In order to prevent this confusion, manufacturing chemists have suggested to the Commissioner of Internal Revenue that the word alcohol be eliminated and that wood alcohol be known in future as "woodine." While this name may not meet with approval, viewed in the light of standard organic terminology, this action is a step toward the elimination of distinctions confusing to the non-technical mind.

Dr. REID HUNT, in a recent bulletin on wood alcohol, prepared at the request of the American Chemical Society, calls attention to the fact that the senses of

taste and smell cannot be relied upon to indicate the presence of wood alcohol and that poisonousness is an inherent quality of the substance, since it is oxidized in the human system to formic acid (and perhaps formaldehyde), while ethyl alcohol is converted into water and carbon dioxide, both harmless and easily eliminated.

In view of the serious consequences which may result from ignorance in this connection, every chemist should devote his energy to the enlightenment of the public regarding the dangers of wood alcohol.

It must be remembered, however, that wood alcohol or methyl alcohol has extensive legitimate uses in the field of chemical industry, and legislators and others should not lose sight of this fact in placing restrictions upon the sale and use of this commodity. The public must be protected, but the accomplishment of this aim must not result in the destruction of a legitimate industry.

Chemicals in A Smelter Flue

A PROMINENT metallurgist recently expressed the hope that the court order dissolving the packing trust might not react unfavorably in the smelting world to the extent of actually impeding recovery of byproducts, a work which he characterized as the most important now before technicians in this industry. His fears, however, appear somewhat magnified. Few Americans object to the slogan "Save all but the squeal," nor its actual realization, since conservation is fundamentally important. Rather, what they do object to is a manipulation of accounts so that economies in general operation are not reflected in the ultimate selling price of individual products to a method whereby the price of meat is all cost and the price of leather or blood all profit, and to a so-called publicity campaign showing that philanthropic butchers of great wealth make the merest trifle on their business. No one can reasonably object because a lead smelter saves, refines and markets its cadmium, and there is small danger of such a plant reaching out into various ramifications of the white-metal founding business because of this minor production. Then they should get into trouble, as have the packers when they market poultry because they have refrigerator cars and cold storage to handle them and strive to control the egg market because eggs are a poultry product. From this it is not a long step to the pillow business to get rid of feathers, and to the manufacture of beds and mattresses, in order to preserve a well-rounded market for the pillows. Thus it is that poultry is dear in order that an independent builder of brass beds in some corner of the country might be squeezed out of business!

Recover cadmium, a lead or zinc smelter must. Time was, and not so many years ago, that the cream of an ore was skimmed, and everything else slagged off, and what wouldn't slag went up in smoke and came down again to the detriment of the surrounding country. Nowadays, what with bag-house, dust chamber and Cottrell plant, very little of even the finest fume gets by, and it is only a question of time when smelter systems will build up to saturation with a dozen little-known and little-wanted elements and their compounds of low vapor tension.

Consider arsenic, as an instance. Any Montana smelter making a consistent effort to abate the dust nuisance rapidly overflowed with arsenic. Anaconda built a little plant fifteen years ago to re-treat some of the richest dust, but the ores even then produced more poison than the whole country could absorb, and a short run demoralized the arsenic market and left the company bare of outlet. As a matter of fact these Western stores of dirty arsenic were handy during the war, and even yet the price remains mysteriously high, but it is only a question of time before large producers of arsenic will actually be compelled to produce other compounds than the oxide. Ridding themselves of this substance will require the popularizing of new insecticides by exploiting their uniformity and low cost, easily possible in large-scale operation on less than valueless raw material.

Cadmium is another instance. Large quantities are available from zinc and lead plants, but no one knows what to do with it. During the war, a considerable amount was used in solders and white alloys in place of more expensive and scarcer metals, but with a relaxation of necessity, its consumption vanished. Again, who knows what tellurium is good for? Smelters have much more of it on hand than they want, but how can it be used?

These are but typical instances of some others which will arrive later. Truly, the utilization of byproducts is the most important now before technicians. But in many of these cases the problem will be broader than merely their isolation in comparative purity; it will comprise intensive research into the properties of the elements, their alloys and chemical compounds. When this is actually done, conservative chemical companies which are not now much interested in buying impure speiss offered by smelters need not expect too much sympathy from the public, which in the long run pays for the acid, the fertilizer, insecticide, alloys and chemical compounds now reposing in a smelter flue system.

Industrial Patriotism And Professional Folks

IN RECENT speeches and press articles, the duty of us folks who are Americans has been definitely pointed out by loyal and able men. The slogan "Industrial Patriotism" was sounded by Mr. JOHN W. O'LEARY in a talk to the chemists at the Chicago National Exposition of Chemical Industries. It doesn't really matter just what we call it or in what manner of words these thoughts of the quiet majority, that is, the middle classes, are expressed, but they are living up to the idea as called by Mr. O'LEARY.

And this appellation "middle classes" is only a name and no longer has any reference to the financial standing of its individuals. We refer mainly to the salaried people who make up this host, to the clerk, the office man, the stenographer, the engineer, the chemist, the professional man and others whose income depends on mind work in contradistinction to the laborer and the capitalist. Apparently the laborer refuses to think and the capitalist is becoming accustomed to paying someone to think for him.

Through all this turmoil and noise industrial, this "word-talk" of individuals with perverted ambitions, we have heard very little complaint from the middle-folks. Their average income is far below that of the hand-worker, who, by the way, has profiteered on the public funds quite as much as the capitalist. And why are these people silent? Not because they are

contented, not because their income is sufficient, nor yet because they do not desire the luxuries of life and a competency for declining years, do they labor patiently at the day's work.

It is because they are well-balanced folks, taught in many a school to think, so that from the examples of the past they can glimpse over the horizon of the future. They know that the reward surely comes in proportion to the effort exerted, that individual progress is in direct ratio to the application and that the progress of society must be evolutionary, never revolutionary. They ask no wage they do not earn, they scorn paternalism. They are busy working at research and study. It was GLADSTONE who said that if hard work was not genius it was a mighty good substitute for it.

Once we knew a humble shipping clerk, hight TOMMY JONES, pointing to no one in particular, who when asked what he did for recreation said, "Work, different kind of work." And he meant it. You can guess where TOMMY is today. What's the matter with the laboring man doing the same thing by adding head-work to his activities? We'll admit his job may be hard and the work sordid. He has only to start thinking to better himself. Self-education is easy in this age. If he hasn't the mental "pep" to "get on," the capitalist can't hand him an "automobile" salary for throwing a lever or swinging a pick. The capitalist, on the other hand, must use the power that is his with honesty and fairness. If he does not he will be elminated by the very laws upon which our business existence is founded.

Both sides of these controversies may well look toward the middle-folks then, as living exponents of real "industrial patriotism." Let them meet at the middle point of view, so to express it, with the soldiers on the job, who have "eyes front" toward the future achievements, and what's more, there is no stirring tune to carry them onward, except, mayhap, the music of the inspired soul.

Steel Supplies
Recent and Prospective

EVEN to those who have followed more or less closely the course of iron and steel production in the past year it must come as a shock to observe that only about 30,000,000 tons can be counted up as the year's pig iron production, while the production of steel ingots and castings can be set at only about 33,000,000 tons. The output of ingots alone in the first half of the year was about 17,500,000 tons.

These figures for pig iron and steel are barely more than three-fourths those of 1916, and since then the productive capacity has been materially increased, so that the outputs are only two-thirds the present capacity, estimated upon a conservative rather than an optimistic basis. In 1917 and 1918 full outputs, in relation to capacity, were not realized on account of various difficulties incident to the times. In 1919 the United States had no foreign war on hand, but it did not have peace at home.

These figures, showing such a wide gap between production and capacity, certainly have a bearing upon the iron and steel market. In many quarters it is being argued that the iron and steel industry is marked for much higher prices. Pig iron has, in fact, advanced fully $8 a ton since July 1, and some observers insist that if steel prices have not advanced, that is only because the United States Steel Corporation has been holding them down. The corporation is very strongly of the opinion that steel prices should not go above the March 21 schedule, arrived at by an agreement between Secretary Redfield's Industrial Board and representatives of the industry, and that if possible steel prices should even be reduced. The Steel Corporation backed up its theory by selling nearly 1,500,000 tons of its products in November, none of the sales being at above March 21 prices.

If an argument that iron and steel prices should be higher in future is based upon a claim that capacity production cannot be realized, on account of various drawbacks, the alleged drawbacks should be plainly stated in order that investigation may be made to determine whether or not the same influences may apply to operations by the consumers of steel. On the whole, it is probable that more work is done on steel to fit it for use than is done in producing it. In other words, the total value of all steel at the moment it is put into employment is probably much more than double its value at the time it leaves the steel mill. If there is going to be a shortage of labor at blast furnaces and steel mills, will there not also be a shortage of labor for making extensions to railroads, for building skyscrapers and for making and using all manner of tools in all manner of industries?

All along the line costs are very high, but the steel industry has also a very heavy overhead. This matter of overhead impels the steel producer to seek large tonnage outputs, but many classes of steel consumers are not similarly influenced. A railroad does not make improvements for the sake of reducing overhead, nor does the factor apply in the case of new building construction.

It seems clear that the fact that production of iron and steel in 1919 has been only two-thirds of the capacity is not an argument that market prices should advance. It is true that steel is very scarce at the moment, but that condition is due to two temporary influences, namely, the iron and steel strike and the coal strike.

Whatever the bearing of production upon the market, however, it behooves all iron and steel producers to seek the greatest tonnages in relation to plant facilities. There has been enough of inefficiency and slackening. As regards its equipment the iron and steel industry is well aligned for full production. There are no weak links in the chain from the raw materials in the ground clear to the finishing departments, though there may be some finishing departments that should have larger capacity, both in relation to demand and in relation to the capacity to produce crude steel. The Lake Superior iron ore mines are capable of producing all the ore needed by the tributary furnaces, the lake fleet is of sufficient capacity, and in the matter of coke many by-product ovens have been built in the past few years and very few beehive ovens have been abandoned. Pig iron capacity is at least 40 per cent greater than before the war, and more than 10 per cent greater than the maximum output yet recorded for a year, while it is quite possible that under favorable conditions the furnaces may exceed ratings based on past performances. Steel producing capacity is at least 40 per cent, perhaps 45 per cent, greater than it was in 1914. Efficient management and efficient labor are the two remaining desiderata for a remarkably heavy production by the industry.

Readers' Views and Comments

Atomic Structure of Metals in Solid Solution

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with much interest the paper in your Oct. 29-Nov. 5 issue on page 566, on the "Atomic Structure of Metals in Solid Solution," by A. E. Feild. While I feel that Mr. Feild's paper will stimulate thought along the lines of interpretation of the properties of solid solution alloys, I cannot agree with some of his general conclusions which would indicate that solid solution alloys consist largely of the amorphous phases of the components. The illustrative example given in his Fig. 2 shows the electrical resistivity of the solid amorphous metal and the solid crystalline metal diverging with decreasing temperature. This is admittedly an illustrative example. In his Fig. 3, however, where the actual examples of gold and silver are cited, the electrical resistivity of the solid amorphous phase and the solid crystalline phase converge with decreasing temperature. As pointed out in one of my papers[1] the convergance of several properties is the rule immediately below the freezing point of the metal, and I am wondering whether any actual examples exist in conformance with the illustrative example shown in Fig. 2.

On page 569, Mr. Feild writes: "A solid solution may then be regarded as entirely analogous to a super-cooled liquid preserving in the solid state all of the electrical properties such as specific resistance and temperature coefficient of resistance of the molten mixture of the components." Farther on he states: "According to our theory hardness in such an alloy is due to the existence of the metal in the amorphous solid state, thus confirming essentially Beilby's theory of the formation of an amorphous phase during cold working of a metal.

"In accordance with this view gamma iron is simply amorphous solid iron which is in solid solution with carbon."

Mr. Feild seems to have entirely ignored the directional and deformational properties of solid solution alloys, their appearance under the microscope, the heat of crystallization on solidification and the heat of fusion on melting, the grain growth phenomena after deformation, the usual crystallization shrinkage on solidification, etc. It might also be expected that an alloy of equal atomic proportions of silver and gold, for example, would show a sharp break in electrical resistivity at the melting range and that Mr. Feild's calculations based on the extrapolation of the electrical resistivity of the amorphous phase from the melting point down to room temperature would not hold at a temperature immediately below that of freezing. Mr. Feild's general conclusions, therefore, are untenable in the face of the existing evidence of the crystalline nature of solid solution alloys.

I do not maintain, however, that the existence of amorphous films between the grains of solid solution metal does not play an important role in the observed properties of solid solution alloys, nor that the atoms in the solid solution crystal are arranged in the same manner as the atoms in the crystals of the pure components. It is highly probable that the electrical and other properties of metallic solid solutions will be explained on the basis of an atomic arrangement and an electron distribution consistent with the present observations on the crystalline nature of solid solution alloys.[2,3,4]

Sulphuric Acid Nomenclature

To the Editor of Chemical & Metallurgical Engineering

Sir:—I have read with much interest the views of Thomas J. Sullivan on "Sulphuric Acid Nomenclature" which I heartily indorse. There is no doubt that there is great confusion in the terms of the various strengths of this important acid, but practically all of this could be avoided by referring to all strengths up to fuming as per cent H_2SO_4 and above this as equivalent H_2SO_4.

Newark, N. J. R. ZELLER.

A New Compensated Heatmeter

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the Oct. 1 issue of CHEMICAL & METALLURGICAL ENGINEERING, a letter to the editor appeared, in which its author, Mr. T. S. Taylor, severely criticises our use of "Heatmeter" as a name for a new instrument of our manufacture. He claims that it is a misnomer, and misleading because heat is not measured quantitatively by means of the apparatus.

Kindly allow us space to explain that in utilizing "Heatmeter" as a trade name, this company merely availed itself of well-established precedents, and adopted a term quite as accurate and descriptive as many others of common usage in pyrometry; such as, for instance, "Multi-Pyrograph," "Hot-Spot-Potentiometer" and "Pyro-volter."

If it were expedient to quibble about the etymology of terms for designating special apparatus in any art, we could appropriately begin with the word "pyrometry," which literally means fire measurement, but I note that Mr. Taylor does not take exception to or comment on its ambiguity.

There are many other technical terms which should be banned, if Mr. Taylor's complaint were valid. For example, a "storage battery" does not store electricity; a "dry cell" is not dry; a "phonograph" does not write sound; a "potentiometer" does not serve to measure, but to balance, potentials; an "electrometer" is not a meter, but a means for comparing the intensity of static charges; and finally, the good old word "thermometer" must be deplorably misleading, because its derivation, from the Greek θέρμη" and the French "métre" makes it identical in its definition with "Heatmeter," and yet nobody is likely to imagine that either of these instruments may be used for the direct determination of thermal units. Hence our reputation is probably not at stake.

High school boys, Mr. Taylor admonishes us, are taught to appreciate the nice distinctions of nomencla-

ture in physics classes. This may be the case; but it may be interesting to learn that it was one of our most distinguished professors of rhetoric and philology at Harvard, who, in lecturing on colloquialisms and slang, told us that expressions such as "open circuit," "lost motion," "booster," "split phase," a "baking frost" and a "frozen bearing" were entirely permissible, and declared in substance that philologists admit that utility, rather than derivation or euphony, determines the adoption of new words or phrases which will constitute a succinct addition to our vocabulary.

Mr. Taylor also asserts I stated that an ammeter takes the place of a pyrometer in the "Heatmeter." If he reads my article carefully, he will note that I used an ammeter merely to demonstrate the fundamental principles of the Harrison-Foote invention in an elementary manner, and that the text describes the instrument as a modified form of precision millivoltmeter or pyrometer.

Chief Engineer,
The Brown Instrument Co.
Philadelphia, Pa.

Controversy Over Dye Licensing System

From the extensive hearings which were recently concluded before a sub-committee of the Senate Committee on Finance, it is very clear that both political parties are perfectly willing to safeguard the domestic dye industry, but that the question of method is very certain to bring on a determined fight when the bill comes before the Senate. The licensing system which it is proposed to apply to the dyestuffs industry will be the chief obstacle to the bill's speedy consideration. Unquestionably more than a majority of the Senate is opposed to licensing, but that they are willing to make concessions in certain cases has been shown by the attitude of many Senators, opposed to the principle of licensing, in the matter of continuing the licensing plan of handling of sugar. Many recognize the dye situation as presenting an exception, and it is not improbable that the Senate may adopt the general plan as set forth in the Longworth bill, which already has passed the House.

Joseph H. Choate, Jr., counsel for the American Dyes Institute, pointed out to the committee the success which has attended the administration of the licensing system in England and France.

General Sibert, in an argument for the stimulation of the dyestuff industry, declared that every chemical plant is a potential arsenal. Admiral Earle testified that the average time to convert a dye-making plant to war uses is three weeks. In a letter to the committee, the Secretary of the Interior urged early legislation. Van H. Manning, the director of the Bureau of Mines, appeared before the committee and pointed out the imperative need for legislation which would stabilize and stimulate the dyestuff industry.

Colonel Fries of the Chemical Warfare Service declared that the effectiveness of the United States in the war was lowered by lack of chemists. Even at the end of the war, he asserted, there had not been enough chemists developed to more than begin to handle the work. Colonel J. H. Burns of the Ordnance Department told the committee that the United States has been behind first-class powers in chemical knowledge.

Dr. M. T. Bogert, professor of organic chemistry at Columbia University, expressed the opinion that the coal-tar industry would have to have protection for ten years largely because of the time required to develop skilled men. He also pointed out that among the 15,000 trained chemists in the United States, not over 10 per cent are trained organic chemists. Dr. Julius Stieglitz of the University of Chicago, testifying in regard to synthetic drugs, declared that many lives and much suffering could have been prevented had we developed our chemical industry in the past. Henry Howard, representing the Manufacturing Chemists' Association, told how the Germans, prior to the war, used our patent laws to maintain a monopoly for their own country on dyestuffs. Henry Wigglesworth, also of the Manufacturing Chemists' Association, believes the licensing can be better administered by a board such as was provided in the original Longworth bill rather than placing the administration of the act in the hands of the Tariff Commission.

The main points made by those opposing the licensing system were that it is in reality an embargo under a different name; that no commission, no matter how composed, could administer a licensing system for dyes without doing great injury to the industry. Not only would the system be cumbersome in operation, it was declared, but it would place an army of $1,500 clerks in control of an important portion of America's business. The effect of the legislation would be very harmful to export trade, it also was stated.

Meeting of A. I. M. E., New York Section

The New York Section of the American Institute of Mining and Metallurgical Engineers held its regular monthly meeting at the Machinery Club, Jan. 7, 1920. Walter C. Perkins spoke on the co-operative system in Russia and gave a very interesting account of the method of organizing co-operative associations in commerce, industry, banking, etc. This method of conducting business has proved highly efficient even among the illiterate peasants of Russia. It has not been popular with the Soviet government, which has made every effort to destroy it. Mr. Perkins was of the opinion that the co-operative system is the best hope for the regulation of the cost of living, eliminating the usurer and the middleman.

Percy H. Thomas described the power development at the Chuquicamata and Braden copper properties in Chile. Natural conditions at the two properties are quite different and call for different types of plant. At Chuquicamata the absence of rivers and the desert nature of the country dictate the construction of a steam-power plant at tidewater, with oil for fuel, and a transmission line to the mines. At Braden, on the other hand, with a plentiful supply of water, a hydroelectric plant was called for. Mr. Thomas illustrated his talk with several reels of film.

Regulation of Engineering Practice by License Issued Under State Laws

In compliance with the instructions of Engineering Council, a committee to frame a uniform bill on the licensing of professional engineers met recently in Chicago. There have been a number of bills introduced in the several state assemblies and about eleven of these have become laws, several of which have been so drafted as to work unnecessary hardship. It has therefore been considered advisable to draft a model bill for introduction by those interested in the various states, in order to supplant or forestall enactments of indifferent origin or harmful results.

Theory and Practice of Catalysis

THE meeting on Jan. 9 of the New York Section of the American Chemical Society was well attended, Rumford Hall being filled to its capacity. Dr. Ralph H. McKee, chairman, opened the meeting. Secretary Herbert G. Sidebottom read the minutes and treasurer's report. He announced that the membership of the section was 1,990, but ten short of giving to the section a twenty-first representative to the Council.

The evening was devoted to papers on Catalysis, the theoretical physicochemical backgrounds being concisely presented by M. Harvey, a preliminary report on the catalytical oxidation of benzene at the Research Laboratories of The Barrett Co. by John M. Weiss and Charles R. Downs, and the action of driers in paints and varnishes by F. P. Ingalls.

Mr. Harvey opened his paper with a discussion of the mass action (1) of the Deacon chlorine process[1]:

$$4HCl + O_2 \leftrightharpoons 2H_2O + 2Cl_2$$

$$\frac{dx}{dt} = k(a - x)(b - x) \qquad (1)$$

where a and b are the initial, x the reacted quantities and $\frac{dx}{dt}$ the velocity. He then stated the gas equation derivative (2) and the fundamental physical law (3) showing the relation between velocity, force and resistance.

$$0.058 \log \frac{P_{O_2} P_{HCl}^4}{P_{H_2O}^2 P_{Cl_2}^2} = 2.3 \log T - \frac{27300}{T} + \text{const.} \qquad (2)$$

$$\textit{Reaction Velocity} = \frac{\textit{Chemical Force}}{\textit{Chemical Resistance}} \qquad (3)$$

From these three equations it can be seen that reaction can be increased in three ways, by increasing the concentration in (1), the temperature in (2) or decreasing the resistance in (3). The action of the Haber ammonia process was explained.

$$N_2 + 3H_2 \leftrightharpoons 2NH_3 + 24{,}400 \text{ Cal.}$$

The reaction is one of chemical compression; 4 mols. of nitrogen and hydrogen being changed to 2 of ammonia with an accompanying heat discharge. Table I is a record of percentage yields of ammonia with changes in temperature and pressure. It will be noted

TABLE I. HABER PROCESS YIELDS

Pressure	550° C.	650° C.	750° C.	850° C.
1 atm	0.07	0.03	0.01	0.009
100 atm	6.7	3.02	1.54	0.87
200 atm	11.9	5.71	2.99	1.68

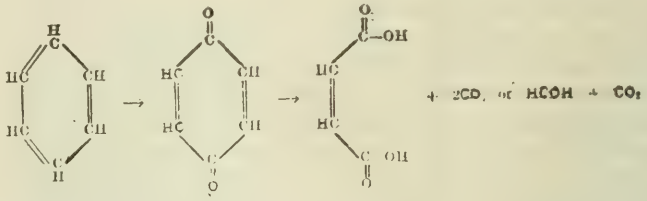
that lower yields are obtained at higher temperatures due to the heat of the reaction not being absorbed as the cooling head is diminished.

The hydrolysis of ethyl acetate in the presence of HCl was discussed from the oxonium and ion-hydrate theories of Falk and Nelson,[2] and H. Goldschmidt.[3]

Photochemical reactions were briefly touched upon from the quantum theory viewpoint. The formula[4] derived by Planck for radiation density was the basis of the discussion.

Mr. Weiss reviewed the literature relative to the previous work done on partial oxidation of hydrocarbons as a means of forming hydroxyls, ketones and new products. No practical results were obtained until 1907, when Orloff in Russia succeeded in producing products from cyclic ring petroleum. The year following the Bayer company took out patents showing that their research laboratory was investigating the field.

It was decided to concentrate on benzene during this investigation because it offered the simpler reactions. The scheme of these is shown graphically in the accompanying drawing. More details than can be given here will be found in the patents recently issued to the authors.[5] The catalyst used consisted of vanadium oxide on pumice. The reaction temperature was between 300



and 500 deg. C. Quinone and maleic acid are produced and seem to have an equilibrium ratio, though higher temperatures and increased amounts of oxygen tend to increase the yield of products of decomposition. The chief difficulty found in controlling these partial reactions is in absorbing the heat generated so as to keep within the temperature limits. In the formation of quinone from benzene 3,000 calories are liberated, and 10,560 in that of maleic acid, while 18,000 are given off in the total combustion to carbon dioxide and water. Very small yields of formaldehyde were obtained, due no doubt to its great reactivity with oxygen at the temperatures used.

The quinone is reduced to hydroquinone, which has a ready market as a photographic developer. The maleic acid is an intermediate for synthetic tartaric and citric acids. The Barrett Co. does not plan to manufacture these derivatives, but will be glad to supply any manufacturer with either the quinone or maleic acid.

The oxidizing action of steam at high temperatures and pressure on benzene was also studied.[6] At 60-lb. pressure and 690 deg. C., 23 parts of C_6H_6 vapor and 27 parts of H_2O gave a fair yield of diphenyl. No phenol was produced. This process furnished an interesting basic study for accounting for the large amounts of tar acid in Scottish tar.

F. P. Ingalls was highly entertaining as well as instructive in his paper on oil driers. He gave the action of lead, manganese and cobalt linoleates as well as the several other so-called oxidizers that have been tried out but not found to be oxygen carriers when in oil. Vanadium and cerium proved to be of no value. Lead ethylate also gave no results. The resinates of lead, manganese and cobalt were valuable, but unfortunately are quite susceptible to adulteration. The older method of boiling the oil with the drier metal oxides has largely been superseded by saponifying the oil and precipitating the linoleates by adding salts of the metals. These are dissolved in turpentine and mixed with the paint or varnish in such proportions as the drying time calls for. Linseed oil containing 0.075 per cent cobalt will dry in 2½ hr., so it will be seen that cobalt is a drying accelerator. Lead is the slower drier, but is preferred because of its smooth film. Paint that hardens too quickly tends to crimp. This is very noticeable with chinawood oil, which when applied to glass gives a somewhat frosted appearance.

Dr. Charles F. Chandler Receives the Perkin Medal

After introductory remarks by Charles E. Sholes, chairman of the New York section, at the fourteenth annual Perkin Medal presentation meeting of the Society of Chemical Industry, Friday night, Jan. 16, and some humorous reminiscences by Dr. M. C. Whitaker, who has been intimately associated with Prof. Chandler for the past twenty years, the Perkin Medal was graciously presented to Dr. Chandler by Prof. Marston T. Bogert of Columbia University.

Dr. Whitaker brought back to mind many incidents illustrating Prof. Chandler's fine personality, generosity, tact and greatness. Prof. Bogert gave a beautiful biographical sketch, reviewing back from 1637, when Dr. Chandler's forefathers came to New England, his early education and schooling at the New Bedford schools, the Lawrence Scientific School, Berlin, Göttingen and lastly his fifty-odd years as a university professor, and dean as well as world-wide chemical councilor.

Dr. Chandler gave an excellent example by presenting his acceptance address extemporaneously. He modestly stated that he had never considered himself as a candidate for the great honor that had just been conferred upon him. He then reviewed incidents taken at random from his life work which he humorously stated might excuse the medal committee. The outstanding features of Prof. Chandler's educational work along with his service as private and civic consultant are no less than monumental and are known to all American chemists about as well as the deeds of Washington. The flash point of lamp oils, ton assay weights, 66 deg. sulphuric acid, Baumé scale standardization, city plumbing regulations, sanitation, plant nuisances, and hundreds of other subjects were initiated by his genius. His titles, "Father of the American Chemical Society," "Dean of American Chemists," are tokens of esteem which can never be represented by even the most precious of metals cast in medals. For a fuller account and the addresses of the meeting, the reader is referred to our next issue.

National Academy of Sciences Establishes a Section of Engineering

The National Academy of Sciences has established a section of engineering. Despite all the comedy definitions from which the engineering professions suffer—a famous toastmaster was described in pre-prohibition days as "Digestion's Engineer"—the fact remains that engineering must be included under the general title of science. If this proposal had been made in the National Academy ten years ago there would probably have been recorded a number of fainting fits among its members. The committee consists of Messrs. H. L. Abbott, J. J. Carty, W. F. Durand, J. R. Freeman, H. M. Howe, F. B. Jewett, G. O. Squier and D. W. Taylor.

New Classification for Chemical, Physicochemical and Physical Phenomena

In the *Journal* of the Washington Academy of Science P. V. Well proposes a new classification for chemical, physicochemical, and physical phenomena, on the ground that recent advances have made the distinction between physics and chemistry both difficult and artificial. He proposes that all forces be classified as respectively, 1, molar; 2, molecular; 3, atomic; and 4, electronic. The corresponding sciences would then be molics, moleculics, atomics, and electronics.

Congress Investigates Expenditures For Nitrate Plants

A SUB-COMMITTEE of the House Committee on Expenditures in the War Department met at the Custom House, New York, Jan. 9-10 for the purpose of investigating the expenditure of $84,000,000 for the two nitrate plants at Muscle Shoals, Ala.

Frank S. Washburn, president of the American Cyanamid Co., testified that his company had offered to build Plant No. 2 with no thought of making a profit, during war time. Government officials decided, however, that the company was entitled to some recompense. As a result, the American Cyanamid Co. received a fee of $1,500,000, of which, Mr. Washburn said, about 85 per cent was deducted in taxes of various sorts and extra expenses cut into the remainder, so that the company made practically nothing. In addition, a contract was drawn up whereby the plants might be operated on a royalty basis by a subsidizing company acting as agent for the Government, for the production of nitrogenous fertilizer materials. The royalty to be paid to the American Cyanamid Co. until its patents expire is ¾c. per lb. of contained nitrogen.

When questioned as to the choice of Muscle Shoals for the location of Plant No. 2, Mr. Washburn pointed out that the simultaneous occurrence of abundant water power and deposits of high-grade limestone and coking coal within sixty miles made the situation unique from the point of view of raw material supply. Labor was also plentiful at the time the project was under consideration.

Possibility of Government Operation

The Government is interested in the manufacture of nitrogenous fertilizer materials under the contract already referred to. As a result of a study made by his company, Mr. Washburn was able to place before the committee statistics from which he had drawn the conclusion that the American Cyanamid Co. can purchase ammonia in the open market for a term of years cheaper than it can produce this compound from cyanamide. Hence, even under Government operation, the plant could not compete with the byproduct coke plants in the production of ammonium sulphate. In Mr. Washburn's opinion, Government manufacture of cyanamide would probably ruin the American Cyanamid Co., since the sale of cyanamide as such is limited (it being used exclusively in mixtures with acid phosphate) and the market is at present nearly saturated, 60,000 tons a year being produced by this company.

Bernard M. Baruch, chairman of the War Industries Board, discussed the nitrate problem during the war period briefly as follows:

Nitrate Program of War Industries Board

Sodium nitrate was admittedly the most important raw material which had to be obtained outside the boundaries of the United States. It soon became evident that Chile could not be depended upon, and a study of synthetic processes was undertaken. It was felt that, even though no plants were built, the knowledge of this possibility would prevent the Chilean producers from increasing their prices for fear of loss of trade in post-war times. With the enormously increased demand for propellants in the spring of 1918, Mr. Baruch saw that there was no possibility of even

the total production of Chile meeting the demand, and asked for four to six ammonium nitrate plants, each to have a capacity equivalent to 225,000 tons of sodium nitrate per year. These recommendations were made solely for the purpose of providing an adequate supply of nitrates for military purposes, and no thought as to the possibility of the cessation of hostilities was allowed to influence the decision. The matter of salvage was also considered of secondary importance.

Joint Committee on Ceramic Research

The National Research Council and the American Ceramic Society have established a joint committee for promoting the investigation of scientific problems underlying the ceramic industry, especially by founding a series of research fellowships whose holders shall devote their attention exclusively to these problems. The members of this committee are: A. V. Bleininger, chairman, ex-officio; Arthur L. Day, Homer F. Stanley, R. B. Sosman, E. W. Washburn, secretary, University of Illinois, Urbana, Ill.

The ceramic industries, including brick and tile making, and general crockery and glass manufacture as well as ornamental potteries, although among the earliest developed by man, have been the last of our great manufacturing industries to reach the status of applied sciences. They have been based for centuries on rule-of-thumb methods, trade secrets, and individual artistry. As far as their artistic features go, science can do little or nothing for them, but in all other ways it can be of great advantage to them.

In sharp contrast to the painfully slow development of these ancient industries is the extraordinarily swift development of such exclusively modern industries as those of synthetic dyes and others entirely based on the discoveries of modern science. The startling success and speed of growth of these are almost entirely the fruit of highly organized scientific research, with methods of scientific control at a young stage of the operations. A famous English scientist is authority for the statement that the capital, large as it has been, which the German dye firms have invested in scientific research has been the best paying investment which the world has ever seen. It is certain that an organized effort to develop the fundamental science of ceramics can have a great influence in advancing the industry.

Coming Meeting of the American Ceramic Society at Philadelphia

Headquarters for the American Ceramic Society meeting, Feb. 23-26, 1920, will be the Bellevue-Stratford Hotel, where rooms are available for general and special meetings, and where social functions will be held. Members of the society are asked to make reservations early, as all hotels in Philadelphia are crowded during the winter months.

Frederick Stanger, manager of the Enterprise White Clay Co., is general chairman of the local committee. Sub-committees have been appointed to assist him. William E. Saunders, of the United Gas Improvement Co., is chairman of the committee on the banquet. W. H. Fulweiler, of the same company, has charge of arrangements for a smoker, or "Section Q." C. H. Applegate, Jr., of the Philadelphia Textile Machinery Co., is chairman of the committee on hotel reservations. C. A. Hall, of the Pennsylvania Salt Manufacturing Co., is making arrangements for the meetings, equipment, etc. George Pettinos, of Pettinos Bros., has charge of the information bureau, and John T. Goheen, of the Brown Instrument Co., is arranging for trips of interest to be taken after the close of the meeting.

A. I. M. E. Annual Meeting

The annual convention and business meeting of the American Institute of Mining and Metallurgical Engineers will be held at the Engineering Societies Building in New York, Feb. 16-19.

Industrial excursions will be made on Thursday, Feb. 19, probably to iron and zinc mines and zinc and steel plants in the vicinity of New York, although it has been impossible to decide definitely this far in advance. In connection with the very important oil sessions, a trip is projected to one or more of the refineries in the metropolitan district.

The tentative program for the technical sessions includes the following papers:

A Foreign Oil Supply for the United States, by George Otis Smith.

Petroleum in the Philippines, by W. D. Smith.

International Aspects of the Petroleum Industry, by Van H. Manning.

Composition of Petroleum and Its Relation to Industrial Use, by C. F. Mabery.

Geologic Distillation of Petroleum, by Baily Willis.

Low-Temperature Carbonization of Coal, by S. W. Parr and T. E. Layng.

Examination of Ores and Metals in Polarized Light, by F. E. Wright.

Reverberatory Furnace for Treating Converter Slag at Anaconda, by Frederick Laist and H. J. Maguire.

Coal-pulverizing Plant, Nevada Consolidated Copper Smelter, by R. E. H. Pomeroy.

Milling Plant of the Alaska Castineau Mining Co., by E. V. Daveler.

Intercrystalline Brittleness of Lead, by H. S. Rawdon.

A Peculiar Type of Intercrystalline Brittleness of Copper, by Henry S. Rawdon and S. C. Langdon.

Relationship of Physical and Chemical Properties in Copper, by Frank L. Antisell.

Blast-furnace Flue Dust, by R. W. H. Atcherson.

Manufacture of Semi-steel for Shells, by Frank E. Hall.

An Experiment in One-piece Gun Construction, by P. W. Bridgman.

Tensile Properties of Boiler Plate at Elevated Temperatures, by H. J. French.

Microstructure of Iron and Mild Steel at High Temperatures, by H. S. Rawdon and Howard Scott.

Physical Changes in Iron and Steel Below the Thermal Critical Range, by Zay Jeffries.

Graphitization of White Cast Iron, by R. S. Archer.

Use of Microscope in Malleable Iron Industry, by Enrique Touceda.

The Coefficient of Expansion of Alloy Steels, by John A. Mathews.

Critical Ranges of Some Commercial Nickel Steels, by Howard Scott.

Forgeability of Iron-Nickel Alloys, by T. D. Yensen.

An invitation has been extended to the members of the Canadian Mining Institute to attend this meeting. A joint meeting with the Electrical Engineers for one day of the session is also being arranged.

Some Chemical Data on Coal Pyrite

A Study of the Use of Coal Pyrite for the Manufacture of Sulphuric Acid—Analyses of Coal Pyrite Samples for Sulphur, Carbon, Arsenic, Phosphorus—Summary and Conclusions

BY H. F. YANCEY*
Assistant Chemist, Bureau of Mines

IN 1917 one-third of the sulphuric acid produced in the United States was made from native sulphur.[1] This represents an abnormal condition in the sulphuric acid industry, because under normal conditions in the past very little native sulphur was used in the manufacture of acid. In 1918, however, owing to the heavy war demands the quantity of native sulphur so used increased greatly over the 1917 consumption. Conditions which necessitated curtailment of the importation of Spanish pyrite ore, and the increased demand, imposed rather critical difficulties on the acid industry. Many manufacturers began burning sulphur instead of pyrite. Under normal conditions such a procedure appears to be bad economic practice and a wasteful use of natural resources. The shortage of pyrite ore gave impetus to various Federal and State governmental agencies to locate adequate sources and deposits of this ore, and to stimulate development of known existing domestic sources.

In April, 1918, a conference of representatives of State Geologists and of the U. S. Bureau of Mines was held at Urbana, Illinois, for the purpose of investigating the possibility of the recovery of pyrite resulting from coal mining operations. The following States were represented: Iowa, Missouri, Illinois, Michigan, Indiana, Kentucky, Tennessee, Ohio, and Pennsylvania. H. A. Buehler and E. A. Holbrook represented the U. S. Bureau of Mines.

The plan adopted at this conference was to make a pyrite survey in each State. Representatives of the respective State Geological Surveys visited coal mines and estimated the possible pyrite production. In many of the mines representative samples of the pyrite or marcasite were taken, and sent to the Middle West Station of the Bureau of Mines at Urbana, Illinois, for determination of their sulphur content. As very little pyrite containing less than 35 per cent sulphur is used in acid manufacture, the determination of sulphur was considered an important adjunct of the survey work. There has not been at any previous time such a systematic investigation of production, and of sulphur content of coal-pyrite ore in the main coal-producing States. The survey indicated that about 1,500,000 short tons of pyrite concentrates could be recovered from coal-mining operations in the Eastern and Central coal fields of the United States.

SULPHUR MINERALS IN COAL MEASURES

The chief sulphur mineral occurring in coal measures is known as iron pyrites, pyrite, or ferric sulphide (FeS_2). Another mineral, known as marcasite, occurs in the coal along with pyrite. As marcasite does not differ in chemical composition from pyrite, it will be included under the general term pyrite in this report. Pyrite from coal mines is sometimes commercially termed "coal brasses" and is called "sulphur" by the miners; other local names sometimes used for coal pyrite are "sulphur balls," "kidney sulphur," "cat faces," and "niggerheads." A "niggerhead" may or may not be pyrite. Some of them consist almost entirely of calcium carbonate, while others are completely pyritized. The mineral pyrite occurs as bands, lenses, nodules, and in very thin leaves in the coal seam. The thin leaves occurring in the cleavage planes are not recoverable, and are therefore not within the scope of this discussion.

Fig. 1 shows a typical pyrite lens with adhering coal. The lens represents a fair grade of pyrite, though streaks of foreign carbonaceous material may be noted in it. Fig. 2 is a view of a typical band of high-grade pyrite adhering to the coal. This particular band was almost continuous and occurred near the top of the coal seam. The lenticular and band pyrite are very rarely so interbedded or intergrown with coal or slate as to be of low grade when freed of outside adhering coal. The figures give an idea of the approximate size of both the lens and band pyrite. These two forms of pyrite are the most important from the standpoint of sulphur recovery in most of the mines. Fig. 3 shows two views of a pyrite nodule, boulder or "niggerhead." The adhering coal has been mostly removed. The upper picture shows a top view of the elipsoid-shaped nodule. The lower picture represents the cross-section, the nodule having been broken with the hammer. The nodule has been completely pyritized. Some of these nodules occurring with the coal have not been completely pyritized, and have only a thin outer layer of pyrite surrounding the limestone center. This form of pyrite is therefore not so important as band and lenticular pyrite.

EXPERIMENTAL WORK ON COAL PYRITES

In this paper the results of sulphur determinations on about 120 samples of pyrite from nine States are recorded. Most of the samples were from Ohio and Missouri. Other samples were from Indiana, Tennessee, Kansas, Kentucky, Illinois, Pennsylvania, and Michigan. About 250 samples of milling products resulting from the concentration of picking belt refuse, washery refuse, and handpicked coal-pyrite ore were analyzed for sulphur. Specific gravity determinations on coal-pyrite containing varying amounts of sulphur are given. The relation of color and sulphur content is discussed. Brief reference is made to impurities occurring with some pyrite ore which rendered difficult ore-dressing operations designed to produce a

*By permission of the Director, U. S. Bureau of Mines.
[1]U. S. Geol. Survey, Mineral Resources, part 2, p. 61; 1917.

high-grade commercial pyrite concentrate. The carbon and arsenic content of pyrite concentrates is recorded because of its bearing on the manufacture of sulphuric acid from such concentrates. The percentage of phosphorus in pyrite from coal mines is given, for a few samples, because of the importance of investigating possible sources of low-phosphorus iron ore.

The results of numerous ore-dressing tests on coal-pyrite ore will be given in a separate Bureau of Mines publication.

Preparation of Samples for Analysis

The samples received from the field were first cleaned to remove adhering slate and coal particles from the pyrite. This was done because the information desired was the sulphur content of the mineral itself, and not of the mineral and its adhering impurities. It is obvious that a milling operation designed to produce pyrite concentrates would involve

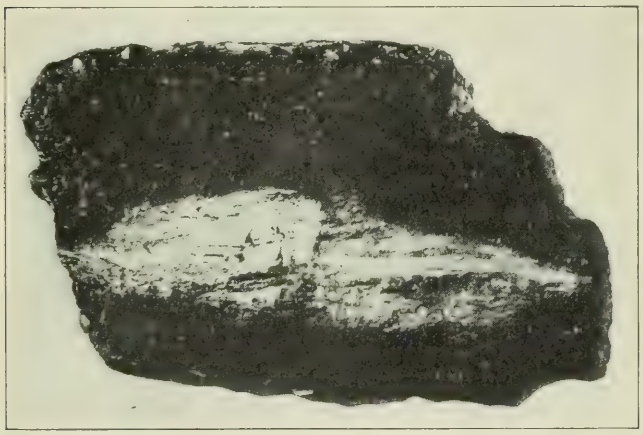

FIG. 1. LENS OF PYRITE (ABOUT ONE-THIRD ACTUAL SIZE)

crushing and washing of the ore so as to remove adhering slate and coal. After the samples were cleaned a brief description of the physical appearance was recorded, and an estimate of the sulphur content of the cleaned mineral was made.

Determination of Sulphur by the Parr Method

The sulphur was determined according to the method of S. W. Parr.[2] One-half gram of the sample, crushed to pass 80 mesh, was weighed into a Parr sulphur bomb and intimately mixed with about 7 to 10 grams of sodium peroxide. About one-half gram of potassium chlorate was then added, and an equal amount of powdered benzoic acid. The lid was then secured on the bomb, and the contents mixed by shaking vigorously. The bomb was next heated over the Meker burner for five minutes; the explosion generally occurred about one-half minute after the bomb was placed over the flame. The heating was continued because the explosion itself does not always give a perfect fusion resulting in the decomposition of all of the pyrite. At the end of five minutes the bomb was cooled under the water-tap, the lid removed, and the fusion crucible placed in a beaker containing about 100 cc. of water. When the reaction had subsided the crucible was washed out, the solution neutralized with hydrochloric acid, and 4 cc. added in excess. The solution was then filtered, diluted to about 300 cc., and the sulphate precipitated from the hot filtrate by the addition of an excess of 10 per cent of barium chloride solution according to the standard method. After standing, the precipitated barium sulphate was removed by filtration, and washed with dilute hydrochloride acid (5 cc. concentrated hydrochloric acid in one liter of hot water). This is followed by several washings with hot water. The precipitate was then ignited at a dull red heat, cooled and weighed.

Other Methods for the Determination of Sulphur

The method described is sufficiently accurate for this study, and more rapid than most of those involving wet oxidation of pyrite. Some investigators have pointed out that barium sulphate should be precipitated from cold[3] solutions containing ferrous,[4] rather than ferric, iron.

These refinements increase the time required for the determination, and were not used because a high degree of accuracy was not required. However, for extremely accurate work on high sulphur materials, such as pyrite, it is probable that the method of Allen and Bishop[4] would be more satisfactory for umpire and sulphuric acid company analyses.[5] They obtain slightly higher results in the absence of alkali chlorides. Allen and Bishop's method requires the reduction of the iron in the solution before the precipitation of barium sulphate; while Smoot[6] advises the removal of this iron, before precipitation of the sulphates, by electrolysis, using a mercury cathode. Allen and Johnston[7] have referred to the disturbing influence of alkali chlorides, and recommend the Carius method of oxidation by heating with fuming nitric acid in a sealed tube. Hulett and Dushak[8] have investigated this subject. The method of Lunge[9] is widely used both in this country and abroad.

Comparative Study of Sulphur Determination Methods

A comparative study of the different methods was made by the joint committee on standard methods for coal analysis, with a very satisfactory showing for the sodium peroxide fusion procedure.[10] References to some of the recent work on the determination of sulphur are given below.[11]

The Parr method was found to be quite satisfactory for all milling products resulting in the concentration of coal-pyrite ore. Some of these products carried considerable amounts of slate and clay, and therefore of silica. This silicic acid did not separate, at the dilution mentioned, when the sodium peroxide fusion was acidified with hydrochloric acid, and even when present in the sample to the extent of 65 per cent did

not contaminate the barium sulphate precipitate.[12] This was determined by evaporating one sample containing 65 per cent silica to dryness, after the water leach of the sodium peroxide fusion had been acidified with hydrochloric acid. The resulting dehydrated silica was then filtered off, and the sulphates precipitated. Several determinations gave a value agreeing very closely with that obtained by precipitating the sulphates directly without previous removal of the silica. This particular sample contained 15 per cent sulphur.

Sulphur Content of Specimens

Ohio.—The State of Ohio was represented by 47 samples. Pyrite investigations were made in about 150 mines. Of the 47 samples examined only 24 per cent contained less than 40 per cent sulphur. Only 4 per cent of the samples contained less than 35 per cent sulphur. The best sample had a sulphur content of 51.2 per cent. The formula FeS_2 requires 53.42 per cent sulphur and 46.58 per cent iron. This sample had the highest percentage of sulphur of any examined during the entire investigation. Mr. W. M. Tucker conducted the investigation in Ohio.

Missouri.—Thirty-six samples of pyrite were collected in thirty-four Missouri coal mines by Mr. Russell Gibson of the Missouri Bureau of Mines and Geology. Twenty-two per cent of the samples examined contained less than 40 per cent sulphur, while only 5 per cent of the samples contained less than 35 per cent sulphur. The best sample showed 48.5 per cent sulphur.

Indiana.—Only one sample of pyrite from Indiana was examined. This contained 46 per cent sulphur. Four samples of concentrates obtained in washing Indiana coal-pyrite ore were found to contain from 44 to 46 per cent sulphur. A report on pyrite in Indiana coal has been prepared by Mr. L. P. Dove and will be published by the Indiana Geological Survey.

Tennessee.—Five samples came from coal mines in Tennessee. All of these samples contained more than 45 per cent sulphur. The specimen having the highest sulphur content analyzed 47.6 per cent. Three lots of hand-picked ore from this State gave high-grade sulphur concentrates with good recoveries of sulphur. In two of these lots the heads contained 40 per cent sulphur.

Kansas.—No samples were collected in Kansas, but one lot of hand-picked coal-pyrite ore was received and concentrated. The head sample of this lot showed 40.3 per cent sulphur. The concentrates obtained by crushing and washing contained 46.5 per cent sulphur.

Kentucky.—Three samples were collected in Kentucky. All three samples contained more than 43 per cent sulphur, 45.6 per cent being the highest. Two samples of washery refuse from a different part of the State were not amenable to concentration, because siderite with some calcium carbonate occurs as a stony impurity along with the pyrite. The siderite and pyrite are closely intermixed, as rather fine crushing, prior to washing, was necessary to give a satisfactory concentrate. The specific gravity of this siderite, being 3.2, rendered the washing and concentration of the ore difficult.

Illinois.—Seventeen pyrite samples were submitted by the Illinois Geological Survey. All but three of these samples contained more than 40 per cent sulphur. The best sample contained 48.9 per cent sulphur. Mr. G. H. Cady made the pyrite survey in Illinois, and the results of his investigation will appear as a bulletin of the Illinois Geological Survey Division. Among the States Illinois ranked third in the production of pyrite in 1917.[13] It is significant that all of this pyrite was recovered in coal-mining operations. Two important papers dealing with this subject have been published.[14]

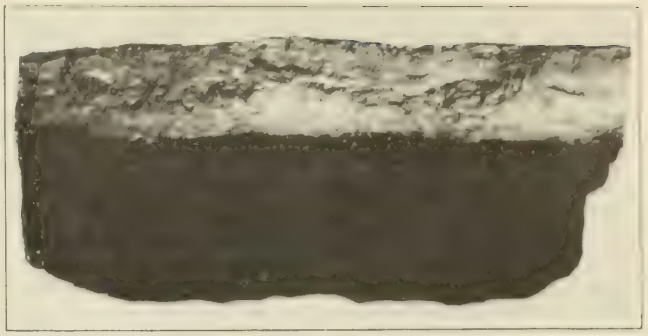

FIG. 2. BAND OF PYRITE (ABOUT ONE-THIRD ACTUAL SIZE)

Pennsylvania.—Two samples of pyrite were received from the Topographic and Geologic Survey Commission of Pennsylvania. They both contained about 44 per cent sulphur. Two samples of washery refuse were examined, both of which contained about 20 per cent sulphur, but which would produce a high-grade pyrite by concentration. Two lots of coal-pyrite ore gave high-grade concentrates with satisfactory recoveries of sulphur on washing.

Michigan.—The coal mines of Michigan were represented by three samples. A washery refuse concentrate contained 41 per cent sulphur. Two samples of pyrite showed 47.2 and 38.5 per cent sulphur. The high-grade sample was dark in color, but dense, heavy and amorphous, while the low-grade (38.5 per cent) sample was brass-yellow, crystalline and much lighter, indicating a lower specific gravity.

TABLE I. SULPHUR CONTENT OF COAL PYRITE

State	Number of Samples Examined	Per Cent of Samples Containing Over 40 Per Cent Sulphur
Ohio	47	75
Missouri	36	78
Indiana	5	100
Tennessee	5	100
Kentucky	3	100
Illinois	17	93
Pennsylvania	2	100
Michigan	3	66
Kansas	1	100

The summory of the sulphur content of specimens is given in Table I.

Relation of Appearance to Sulphur Content

The mineral pyrite generally occurs as brass-yellow cubic or other isometric crystals. Marcasite differs from pyrite in crystalline form only in that it is generally lighter in color, and has a slightly lower specific gravity.

As has been previously mentioned, a record was made of the physical appearance of the sample. By comparison of this record with the sulphur content

[12] Hillebrand, W. F., U. S. Geol. Sur., Bull. 422, pp. 196-198; 1910.

[13] U. S. Geol. Survey, Mineral Resources, part II, 26; 1917.

[14] Holbrook, E. A., "The Utilization of Pyrite Occurring in Illinois Bituminous Coal," Illinois Univer. Engineering Exper. Sta., Aug. 20, 1917. Pogue, J. E., "The Pyrite Situation With Special Reference to Coal Mining in Illinois," 4 pp., Illinois Geological Survey, October, 1917.

it was early found that the color of the specimen did not give an accurate indication of probable purity. In fact many of the coal-pyrite specimens containing more than 45 per cent sulphur were dirty-gray or brown in color, dull and non-crystalline even on fresh fracture. Samples of bright brass-yellow crystals of pyrite from Virginia and Georgia pyrite mines (not coal mines) were often found to contain less sulphur than dull, dirty-gray specimens of pyrite from coal. In several instances samples of pyrite from coal, having a brass-yellow, crystalline appearance, were found to be rather low in sulphur.

In a general way it was found that the estimation of the grade of a coal-pyrite specimen (sulphur content) should be based upon its apparent specific gravity when "weighed" in the hand, rather than upon its color or structure.

The specific gravity of pure pyrite is given by Dana[15] as 4.95 to 5.10, and by Moses and Parsons[16] 4.9 to 5.2. The same authorities give the specific gravity of marcasite as 4.85 to 4.90 and 4.6 to 4.9 respectively. The specific gravity of several samples of pyrite from coal mines is given in Table II. The corresponding sulphur determination was made on a portion of pyrite from the same piece as that used for the specific gravity determination, except in the case of the sample from Ohio, when both determinations were made upon the finely pulverized sample.

TABLE II. SPECIFIC GRAVITY OF COAL-PYRITE

Lab. No.	Per Cent Sulphur	Specific Gravity
Tenn. 11	15.1	2.70
Ill. 18	25.5	2.89
Ill. C-17-51	29.7	3.62
Ill. C-18-20	42.0	3.99
Ill. C-18-62	44.0	4.41
Ill. 22	46.7	4.09
Ill. C-18-68	48.9	4.32
Ohio 111A	51.2	4.76

It will be noted that sample 111A from an Ohio mine contained nearly the theoretical (53.42) per cent of sulphur, and showed the highest specific gravity. This is to be expected. Even this sample has a specific gravity too low to meet Dana's value for either pyrite or marcasite, but does come within the limits given for marcasite by Moses and Parsons. As shown in the table the specific gravity of pyrite does not increase directly with the sulphur content. It is apparent that variations in the specific gravity of the non-pyritic material would account for these variations.

Carbon in Coal-Pyrite Concentrates

It is generally assumed that carbon dioxide exercises an injurious action in the lead chambers, and for this reason "coal-brasses" have not been considered good raw material for the manufacture of sulphuric acid until quite recently. It now seems that this assumed injurious action was due to inaccurate information, or to difficulties encountered in making sulphuric acid from roughly hand-cleaned coal-pyrite ore containing from 10 to 25 per cent coal with its accompanying volatile matter. The maximum amount of carbon in pyrite concentrates allowed without penalty is generally 8 per cent. Lunge[17] states that a Bohemian works is making sulphuric acid from a material containing 10 per cent bituminous material without any special trouble. Pyrite concentrates from a pyrite washery contain much smaller amounts of carbon, and apparently do not cause trouble in the manufacture of acid. Some figures on the carbon content of pyrite concentrates are given in Table III.

TABLE III. CARBON CONTENT IN COAL-PYRITE CONCENTRATES

Product	Total Sulphur Per Cent	Total Carbon Per Cent	Organic Carbon Per Cent
First Bed Pyrite Concentrates	44.77	2.90	2.27
Pyrite Lump Concentrates	45.88	2.60	1.83
First Hatch Pyrite Concentrates	45.03	3.75	2.96
Recleaned Pyrite Middlings	43.88	6.76	6.61

Analyses made at the Pittsburgh Station, Bureau of Mines.

In this connection Parish[18] has called attention to some of the difficulties met in the manufacture of sulphuric acid from coal-pyrite. He states that coal-brasses should contain a minimum of 38 per cent available sulphur, and ferrous sulphate not to exceed

FIG. 3. BALL OF PYRITE (ABOUT ONE-THIRD ACTUAL SIZE)

6 per cent. He recommends the use of a nitric acid feed on the Glover tower, and points out that carbon dioxide occupies valuable chamber space in the system. Excessive amounts of iron sulphate would not

be present in a freshly prepared pyrite concentrate. Thereafter, the amount present would depend upon the conditions of and the length of time in storage, as well as upon the mineralogical and physical characteristics of the pyrite. Experience seems to indicate that under average conditions the formation of iron sulphate would not materially affect the value of coal-pyrite concentrates, but storage for more than a year might be inadvisable.

In connection with storage, the tendency of coal pyrite to fire spontaneously must be considered. It is well known that hand-picked pyrite, containing, as it does, generous amounts of coal, takes fire quite readily during storage. Information covering the storage of washed pyrite concentrates, which ordinarily contain less than 5 per cent of carbon, for long periods of time are not available. However, pyrite washeries in Illinois have never experienced appreciable heating or firing of washed concentrates during storage for several months.

Arsenic in Coal Pyrites

Arsenic is poisonous, and has an especially injurious effect on the production of sulphuric acid by the contact process. According to Hjelt[19] Spanish pyrite from the Rio Tinto district contains an average of 0.91 per cent arsenic. Pyrite recovered from coal-mining operations showed much less of arsenic in six samples examined. A sample from Pennsylvania supposed to be high in arsenic contained 0.056 per cent. A sample of concentrates from an Illinois pyrite washery having an output of 1700 tons of pyrite concentrates per month showed only 0.029 per cent of arsenic. Another Illinois pyrite washery concentrate contained only 0.005 per cent. The first hutch product obtained in jigging several hundred pounds of Ohio coal-pyrite ore contained 0.005 per cent arsenic. A similar product, but from Tennessee, had an arsenic content of 0.015 per cent. A jig concentrate on Pennsylvania ore contained 0.039 per cent arsenic. The results on these samples can be taken as fairly representative of coal-pyrite concentrates, and show that the arsenic content of this material is negligible.

Phosphorus in Coal Pyrite

The clinker or cinder remaining after burning off the sulphur from pyrite has been utilized as an iron ore. The material is generally so fine that it requires agglomeration or nodulizing, as well as roasting, to remove the remaining sulphur. Several other factors determine its suitability for use as an ore of iron, but because of the present low-phosphorus iron-ore situation, it was considered advisable to determine the amount of phosphorus present in coal-pyrite. Ten samples of pyrite concentrates were obtained at pyrite washeries and from milling tests on half-ton lots of coal-pyrite ore. The percentage of phosphorus found to be present in the pyrite varied from 0.003 to 0.083 in these concentrates. Seven of the samples contained less than 0.015 per cent phosphorus, while four showed less than 0.008 per cent phosphorus. It is apparent that a considerable portion of the burnt coal-pyrite cinder could be used for the production of low-phosphorus iron. In England the cinder is used in the manufacture of paint.[20]

[20]Parish, P., *Gas J.*, vol. 141, p. 246; 1918.

Summary and Conclusions

Most of the pyrite occurring with coal contains economic and useful percentages of sulphur.

Color and physical appearance do not indicate probable sulphur content.

Properly prepared pyrite concentrates do not contain injurious amounts of carbon.

Pyrite from coal contains only very small amounts of arsenic.

Pyrite from coal is mostly low in phosphorus.

Acknowledgment

The work described in this paper was carried out under the direction of E. A. Holbrook, to whom acknowledgment is made.

This report was prepared under a co-operative agreement among the Illinois State Geological Survey Division, the Engineering Experiment Station of the University of Illinois, and the U. S. Bureau of Mines. The work was conducted in the Mining Laboratory of the University of Illinois.

Furnace for Testing Firebrick Under Load at High Temperatures

By C. H. Lovejoy

THE proposed standard test for firebrick under load at high temperatures, outlined in the 1918 *Proceedings* of the American Society for Testing Materials, and more extensively described in this journal of date Jan. 1, 1918,[1] leads me to write this description of a furnace for similar purpose, which has been used by the Pittsburgh Testing Laboratory, Pittsburgh, Pa., for the past five years. The main differences between these furnaces lie in the manner of applying the load and the means of determining the load at any time during the progressive failure of the brick under test.

The apparatus consists essentially of a firebrick chamber in which the test brick is heated while a pressure is applied at the ends. We use a pressure of 50 lb. per sq.in. (double that recommended), which will produce ultimate failure in all but the best brick when the temperatures mentioned in the proposed test are attained. By applying the load with a spring instead of levers, we are able to carry practically all our tests to ultimate failure, determine the variation in load sustained by the brick at the higher temperatures, and obtain an idea of the rate of failure. The spring we use is easily removed and frequently checked up in our testing machine. This is mostly a matter of form, for when in use it is never stressed to capacity, and we have found no appreciable differences in it during the five years it has been in service. When compiling our results we plot a load-temperature curve as well as a time-temperature curve. As a rule we try to have our time-temperature curves alike and draw our conclusions from the load-temperature curve.

The apparatus is best described by outlining the procedure followed in making a test. The brick to be tested, *T*, is placed in the center of the furnace (Fig. 1); the upper end blocked to the roof with half of a refractory brick, the lower end blocked to the moving piston, *P*,

[1]"A Furnace for Testing Refractory Materials Under Load at High Temperatures," Robert J. Montgomery. Met. & Chem. Eng., vol. 18, No. 1, p. 18, Jan. 1, 1918.

with another refractory brick. To guard against eccentricity in loading, a very thin piece of sheet asbestos is placed between the blocks. The opening in the bottom of the furnace is closed by a piece of heavy asbestos board fitted around the lower blocking brick.

The piston *P* is raised by turning nut *N* until the brick to be tested and the blocking are in firm contact with each other. The length of the uncompressed spring is now measured accurately. Further turning of nut *N* will produce compression in the spring and bring pressure to bear on the end of our test brick. For each inch of compression in the spring we use, we obtain 400 lb. load. Suppose the end area of our brick to be $2\frac{1}{4}$ in. x $4\frac{1}{4}$ in. = 9.56 sq.in. at 50 lb. per sq.in. = 478 lb. total load to be applied. This will be obtained by continuing to turn nut *N* until the spring is compressed 478 ÷ 400 = 1.19 in.

The two gas burners at *B* and *B* (Fig. 2) are lighted, at first without any air blast. These burners are staggered so that no flame shall impinge upon the test specimen. When the furnace has reached 500 deg. C. the door *D* is blocked, the blast turned on, and regulated so as to reach 1350 deg. C. in five hours, and maintained at this temperature for one hour. Furnace temperatures are read every 20 minutes by an electric pyrometer inserted through *H*, opposite the brick. The amount of compression in the loading spring is measured at the same time. Very poor brick will start to fail and bulge in the middle as low as 950 deg. C. or 1000 deg. C., the load falling off in proportion as this deformation reduces the amount of compression in the spring. Such brick will show complete failure below 1200 deg. C., the spring having returned to its original length, the load reduced to zero. This class of brick is not useful in arch construction or other work where it is necessary that the brick stand a load. Fair brick will start about 1100 deg. C. and still have about 25 lb. per sq.in. left on them at 1350 deg. C. First-class brick will generally show no signs of failure before 1200 deg. C. and many will stand 1300 deg. C. before starting to fail. We have found only two brick that would show no signs of failure at 1350 deg. C. If desired the temperatures may be carried above 1350 deg. C. to whatever point is necessary to produce complete failure; always at temperatures below 1500 deg. C.

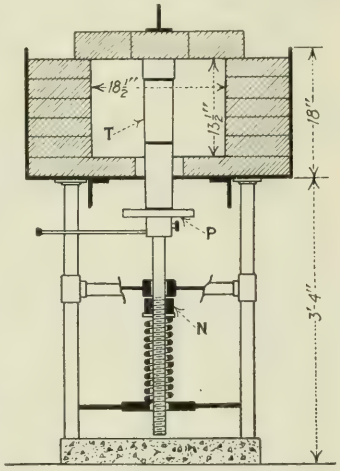

FIG. 1. SECTION THROUGH FURNACE

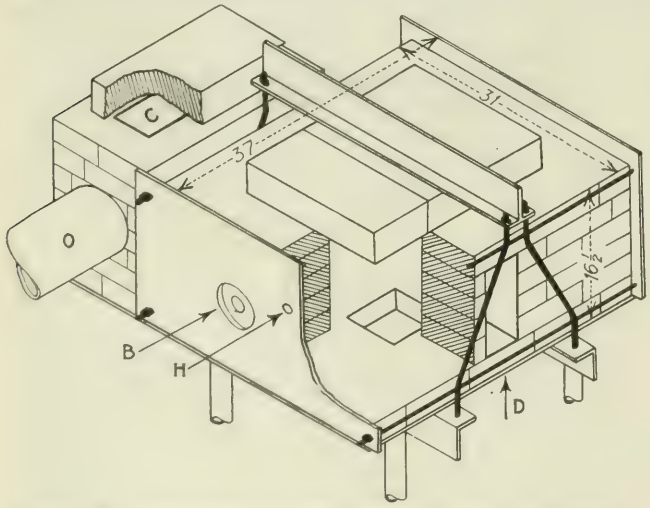

FIG. 2. ISOMETRIC VIEW OF HEATING CHAMBER

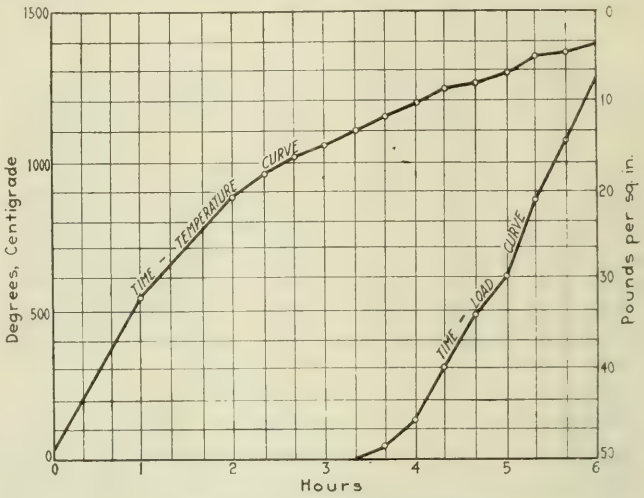

FIG. 3. TEST OF FAIR QUALITY FIREBRICK

Considerable difficulty was experienced with the original furnace through the frequent melting off of the outlet pipe carrying away the gases, until the extra chamber *C* was built on the rear of the furnace.

In the proposed standard test using the lever furnace, the load remains constant, and different rates of heating are recommended for different qualities of brick, always stopping short of ultimate failure. In our work we receive samples from many sources in which the main question is not what this specimen will stand without failing but what this brick is good for and where it will fail. Our furnace enables us to arrive more quickly at the answer to this question.

For general testing and variety of service we have found this furnace very satisfactory. The metal work is simple and easy to assemble; the spring insures straight line application of the load; the brick work is made without special shapes and is easily laid up; and the whole furnace is compact and was moved twice in the last year with a minimum of effort.

The credit for the general design of this furnace belongs to J. B. Shaw, who built the original furnace. Several attachments have been added by other members of our staff for the purpose of making it automatic and self-recording, but it is not essential to describe them here.

Pittsburgh Testing Laboratory,
Pittsburgh, Pa.

Extension of General Import License

The general import license has been extended to cover salvarsan, neo salvarsan, arsphenamine, and all substitutes and equivalents therefor, and narcotics. The effective date was Jan. 10. Individual import licenses therefore will not be required for these commodities except when shipments originate in that part of Russia under control of the bolshevik authorities.

Reminiscences of Early Years at the Great Falls Smelter

Brief Notes of the Early Development of this Once Great Copper Concentrator and Smelter, Particularly as Affected by the March of Events in the Metal and Share Market Ore Supply and Metallurgical Science

By CHARLES H. REPATH

Consulting Engineer,
Sometime Chief Engineer, Boston & Montana C. C. & S. M. Co.

AFTER operating for more than 20 years, the concentrator at Great Falls, Montana, was closed down somewhat before the outbreak of the war. It was maintained in operating order, however, for many months, but finally the machinery was removed, scrapped or disposed of as opportunity offered.

The definite passing of this mill—perhaps the oldest in the Rocky Mountain copper regions—where were solved many of the problems underlying the mammoth operations of today, warrants more than perfunctory mention. In fact, during the '90s the plant was known as the "last word" in copper, its pre-eminence falling only with the completion of the large Washoe works in Anaconda. Even thereafter, the staff was continually working on the betterment of the milling and smelting practice, and was able to make refinements in principle and method which have been of wide application elsewhere. Possibly, then, these reminiscences of early years at this plant may be of more than casual interest.

The Boston & Montana Consolidated Copper & Silver Mining Co.—or more briefly, as it is still known, the "B. & M."—was organized with a moderate capitalization late in the '80s, and owned some Butte mining properties on the northeasterly end of the then productive copper zone. It also owned two small plants near by in Meaderville—the upper works, and the Colusa, or lower works, one of which embodied, by the way, the first copper concentrator started in Butte, a 25-ton mill erected in 1881 by A. Wartenweiler for the Montana Copper Co. to produce jig concentrates of copper glance from Colusa ore. The early B. & M. operations were quite profitable, and in 1889, when it was decided to increase the smelting capacity, the first steps were taken by the management in the issuance of a $500,000 bond issue to cover construction. At that time the output was a high-grade matte which was shipped to England for refining—the monthly production contained about 2,000,000 lb. of copper and 14,000 oz. of silver.

A New Smelter Authorized

It was not easy to determine the correct location for what was then thought to be a large smelter. Available sites in Butte were cramped, water was scarce, coal and coke expensive, and the existing sulphur smoke unendurable. A much more favorable area was purchased in Cascade county, on the north bank of the Missouri River, just below Black Eagle, the first of a series of wonderful waterfalls which have but recently been utilized. Here was available power to drive machinery and pumps, ample water for concentration, and a big river into which tailings and slag could be sluiced. At Belt or Sand Coulee, within a few miles, was located extensive deposits of bituminous coal, already developed and supplying locomotive fuel at about $1.75 per ton. Unfortunately, however, the site was 175 miles from the mines across the continental divide, and the question whether ore should be hauled to the coal or coal to the ore was argued at length. A favorable freight rate (65c. per ton) was negotiated, however, and tentative plans were adopted for a 2-section 500-ton concentrator, Brückner roasters, producers for gasifying the bituminous coal and tilting open-hearth smelting furnaces.

Mr. Charles O. Parsons, the general manager at that time, employed Mr. Frank Rossberg, a concentrator man from Anaconda, to design the mill. The first question was the method of crushing to be employed—whether to use the steam stamps so successful in the Michigan copper country or the jaw crushers and rolls thought to be more applicable in Butte. Montana milling practice had been strongly influenced by Michigan ideas at a somewhat earlier date, when Marcus Daly went to the Calumet & Hecla to get a man to design a new mill at Anaconda, fortunately securing the services of Otto Stahlman, then working as draftsman under John Ellenbecker. Daly was much impressed with the magnitude of the operations in Michigan, and while the old mills at Anaconda had already demonstrated the efficiency of crushers and rolls, they were rather small installations and Daly threw aside all their accumulated experience for the "bigness" of a stamp mill. Rossberg, although originally a Michigan steam-stamp proponent, had a very open mind and knew that the stamp was far from perfect, and while the cost of stamping was much less it produced many fines, causing a tremendous loss in values. Great Falls construction was therefore delayed for months through 1890 on account of this controversy between what might be differentiated as the Anaconda system and the B. & M. system of concentration. The former, as noted, exemplified Michigan practice using steam stamps, hydraulic separators, Collom jigs, and revolving slime tables. The B. & M. Colusa mill attempted to reduce sliming by crushing in Blakes and Cornish rolls, and to cut down the water consumption by screening in trommels, then concentrating on Hartz jigs and vanners. Evidently a proper choice required the decision of fundamental questions.

Character of Site at Great Falls

Tentative ground plans and cross-sections were adopted, however, sufficient to allow excavation and foundation work to proceed. The site chosen was against a steep river bank, close to the falls, where power could be transmitted from the wheels by rope drives, and where the huge quantities of water required

could be readily available. How big an item the latter was can be appreciated when it is known that the 500-ton mill required 240,000 gal. of water per hr.—many times what would be used today. The excavation was enormous—a series of benches were dug into the hillside, mostly in a water-bearing shale, exceedingly tough when fresh, but rapidly disintegrating into a slippery clayey mass on exposure. Immense rock retaining walls were therefore necessary, not only to hold up the benches, but also to withstand the impact of the steam stamps, should they later be installed.

The delays due to indecision as to plans and to extra heavy work, the overrunning of estimates, and the expanding construction program caused much dissatisfaction with the Great Falls management, and called for a second bond issue of $600,000 to complete the smelter. In order to find out the exact status of affairs, the Eastern management in the spring of 1891 asked Captain Daniell and Frank Klepetko of the Tamarack Mining Co. to inspect construction operations, in company with

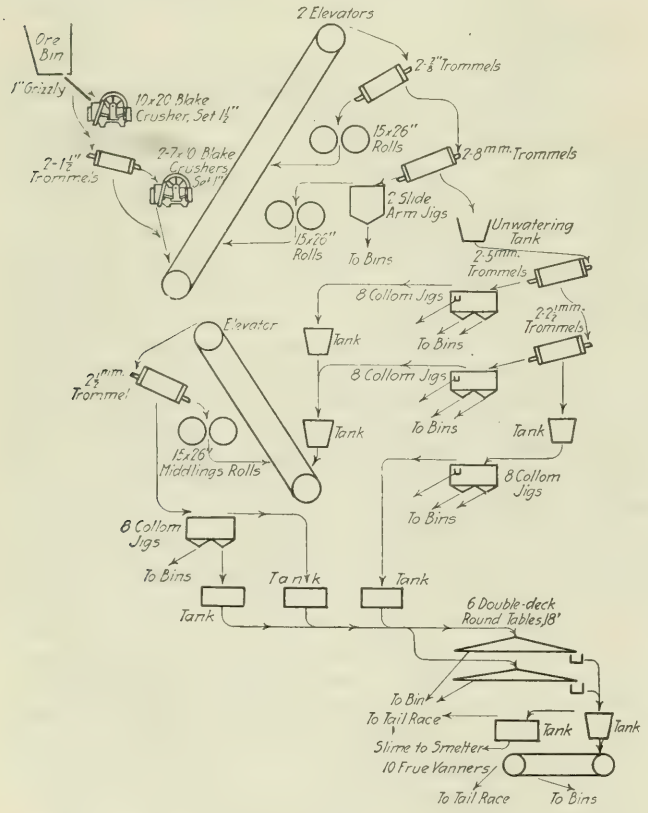

FIG. 1. ORIGINAL FLOW SHEET OF CONCENTRATOR, 1892.

Thomas Couch, Butte manager of the B. & M., and C. H. Palmer of the Butte & Boston. Their report quieted much of the official apprehension, and Mr. Klepetko was soon after retained as manager, being given instructions to push the work to completion with all possible speed. After investigating the concentrator problem, he decided against steam stamps and ordered the installation of the Butte system. This was accordingly done, and the mill started in March, 1892.

Original Mill

A brief description of the original mill follows: Concentrating machinery occupied two-thirds of a wooden building, 136 ft. by 262 ft. in dimensions. Ore was delivered to wooden storage bins of 3600 tons capacity, crushed in 10 by 20 and 7 by 10 Blake crushers and 15 by 26-in. rolls, and concentrated in slide arm jigs, Collom jigs, and double deck round tables whose tailings were finally treated on Frue vanners, all as shawn on the flow sheet (Fig. 1). This machinery was driven by two 44-in. water wheels, from which a 400-hp. manilla rope transmission went to the mill, together with a 250-hp. transmission to the smelter. A 40-in. wheel was also used in the power house to drive two rotary pumps, furnishing 3500 gal. per min. through a 24-in. riveted pipe, about 1000 ft. long. The remainder of the mill was occupied by a 22 by 48-in. Corliss engine for reserve power, and a 15 by 30-in. Ball steam stamp for reserve crushing.

Early operations in the mill were fairly satisfactory from the viewpoint of recoveries. Many troubles appeared due to disproportionate spouting and splitting of feeds, but such difficulties were encountered ten years later when the Washoe mill started. Shortly after concentration commenced, Mr. Klepetko brought Mr. W. A. Estabrook over from the B. & M. plant in Butte to be superintendent of the concentrator, Mr. Rossberg leaving to work up a centrifugal milling machine for some Helena people. Estabrook made a number of changes which, while not affecting the general flow sheet greatly, practically rebuilt the entire plant and brought the mill up to its rated capacity of from 500 to 600 tons per day. Rolls, elevator boots and heads, trommels and launders were raised or lowered for more adequate service. During all this time there was a continual struggle with poor machine design—constant and vexatious delays due to breakages in crushing, jig or table division resulted in new designs and local construction for nearly every piece of machinery in the concentrator.

Smelting Practice

Meantime the smelting departments were not having an easy time of it. These were arranged as shown in Fig. 2, housed in a light steel building 230 by 455 ft. in dimensions, built by the Berlin Iron Bridge Co. (at a cost of about $60,000, by the way!) Roasting was done in 24 Brückners, then the perfection of roasting practice, with a rated capacity of 16 tons per day; actually about 250 tons of concentrates were calcined. In the design of the metallurgical machinery, Julian Kennedy of Pittsburgh was retained as consulting engineer, and the plant showed many points of similarity to steel-works practice. Twenty-four Wellman gas producers supplied gas to eight matte furnaces (Fig. 3)—small tilting open-hearths operated with hydraulic cylinders and with regenerative checkerwork. Six of these were gas-fired, while two, owing to lack of capacity in the producers, were operated experimentally by direct coal-firing. Slag was granulated and sluiced to the Missouri River below—a most economical disposal which continued until three or four years ago. A high-grade matte was produced, crushed, sacked and shipped to New York. Later it was handled in pots by one 20-ton overhead crane to two converter stands, each designed for 5 tons of matte. (Seventeen-pound air was furnished through 1600 ft. of 30-in. riveted pipe from a blowing engine near the water wheels.) The detailed construction of these stands was very similar to those at bessemer steel plants, with sectional shells, and hydraulic operation centrally controlled from a pulpit. It was originally thought that only the

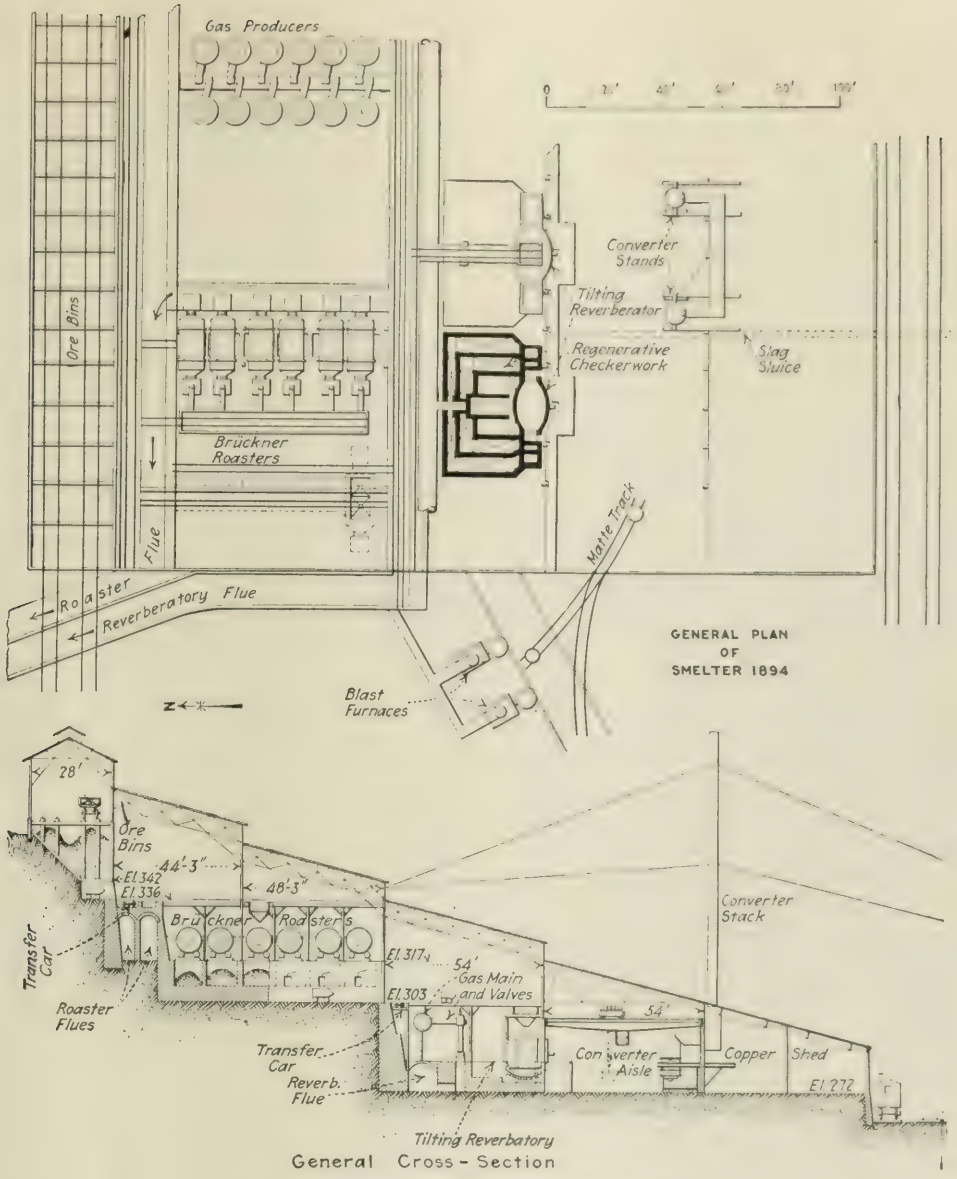

FIG. 2. GENERAL DRAWING OF SMELTER, 1894

bottom and tuyere section of the converter would need relining at intervals, but operation quickly demonstrated that corrosion went higher, and the lining had to be rebuilt after about five blows. For this reason one stall was out of commission constantly, and two more stands were immediately constructed in order to treat all the matte. An interesting forecast of the well-known propensity of Great Falls engineers toward large converters is that as early as the middle of 1892 Manager Klepetko reported that serious consideration was being given to the question whether larger converting shells would not be advisable. The steady growth of these embryonic ideas has been interestingly set forth recently, however, by Messrs. Wheeler and Krejci in the Montana volume of the Transactions of the American Institute of Mining Engineers, and therefore need not be repeated here.

Troubles in Gasifying Low-Grade Coal

Most of the grief in the smelter could be traced back to the gas-producers, however. With from six to eight reverberatories in operation, 350 tons of calcine could be easily handled, even if one of the furnaces was used as a matte well. This was the equivalent of 1000 tons of concentrating ore such as was being delivered to Great Falls (7 to 9 per cent copper!) or even less of the even richer "second class" ore then being treated at Butte. The Great Falls concentrator's product analyzed about as follows:

Copper, per cent	14 to 18
Sulphur, per cent	39
Silica, per cent	13
Iron, per cent	28

All of this had to be smelted in the reverberatories, so no coarse concentrates were made. Indeed, in order to supply the deficiency in calcine considerable first class ore (40 to 50 per cent copper) was fine-crushed in the smelter and sent to the Brückners! The reverberatories seemed to work fairly well when supplied with good gas and hot calcine (sulphur 8 per cent) producing a matte with 50 to 60 per cent copper and containing 19 to 20 oz. of silver per ton of blister. A satisfactory slag ran about 30 per cent silica, 60 per cent iron oxide, 8 per cent alumina, 0.6 per cent sulphur, and 0.7 per cent copper. Converter slag was handled as follows: After a reverberatory had been tilted and skimmed, a ladle of

hot converter slag was run into the matte-furnace, when the intimate contact between slag and "copper bottom" reduced the copper content to approximately that of a normal reverberatory slag. After a sufficient time had elapsed with the furnace under gas, it was again skimmed and was ready for another charge of calcine.

By the spring of 1893, however, it was demonstrated that the method of heating was defective. With the dusty, low-volatile, high-ash fuel available, it seemed impossible to make rich gas continually. In order to smelt at all, then, very hot calcines were essential, which the Brückners would only produce from a fine, dusty charge. To complicate matters, the producers were placed on a bench some 45 ft. vertically above the regenerator ports (see general cross-section in Fig. 2), and it was therefore necessary to run them under high pressure in order to force the hot gas down into the checkerwork. This in turn necessitated high blast-pressure on the producers, with an attending high content of CO_2. Troubles were multiplied in winter, when the occasional stretches of severe weather separating the ever-blowing chinooks would freeze up everything—even a water pipe with a fire under it would not remain open through a week of 30 below!

It was many months, even years, before all these troubles were straightened out. Taylor producers were immediately bought and tried with somewhat more success. Finally a tight, warm, stone building was erected at a low elevation across the end of the converter aisle, and producers, largely of local design, installed. As shown in Fig. 4, these were cylindrical shells, with a rotating grating ring. Ashes were periodically raked out from the pit into sluices. Steam jets injected combustion air into the charge, and gas was drawn off below a revolving top, from which projected four water-cooled stirring arms. The coal itself had to be crushed to hazelnut size and all fines carefully screened out—a mechanical feeder periodically dropped a quantity of this clean nut into the shaft. Slack from the coal crushing and screening plant was trammed to a boiler house and used to make stean for the blast; any excess was sluiced to the river. The gas itself was very sooty and dusty even when made of this clean nut, and the gas mains were consequently enlarged to ample capacity, and provided with the necessary drains and manholes so that the accumulation of fluffy carbonaceous material could be hosed out at relatively short intervals. As an illustration of the material these producers gasified and their product, the following 1910 analyses may be interesting:

Coal:—Total H_2O, 7.7 per cent; combined H_2O, 1.3 per cent; volatile matter, 27.0 per cent; fixed carbon, 48.8 per cent; ash, 22.8 per cent; B.t.u. 10,173.

Gas:—CO_2, 9.2 per cent, CO, 13.9 per cent; CH_4, 2.1 per cent; H_2, 15.4 per cent; N_2, 59.4 per cent.

Reflex Upon Finances

All these troubles could not help but be reflected in the cost sheets, and the Great Falls project was an easy butt of all kinds of criticism. Previous to its inception the newly formed B. & M. company was able to show a very good balance sheet and paid regular dividends—its Butte plants were smelting nearly 400 tons of ore per day, at a cost of about 9¾c. per lb. of copper in matte f.o.b. New York City. These profitable operations still continued, and the new plant at Great Falls was not at first able to equal their performance. About $900,000 had been expended for new construction, the smelter had been put into operation months later than promised, and was possibly absorbing all the money Butte operations were able to clear, since no dividends were being paid, even at an average price of 10¾c. for copper. "B. & M." was regarded as a highly speculative issue on the Boston mining exchange, and was steadily declining from about 35, when the new smelter started, to 16 in the middle of 1893. Of course, the general panicky conditions of this year were reflected in this price, but the quotation was only 26 when dividends were finally resumed in 1894. As a matter of fact, the B. & M. weathered the free-silver storm more fortunately than other Butte companies—it was the only concern which operated continuously throughout, producing about 3,000,000 lb. of copper monthly. (In the fall of 1893 not more than 500 men were at work in the Butte mines as compared to the payroll of 9000 six months before.) According to the annual report the company apparently was insolvent with a balance of $450,000 in liabilities on July 1, 1893, but this was changed in three months to an asset balance of $205,000. Compare quotations of 16 to 26 with the price of around 475 just before the stock was withdrawn from listing after the company's absorption by Amalgamated!

Changes and Additions in 1893

In the face of such conditions it required no little courage to recommend further expansion at the new

FIG. 5. ONE SECTION OF CONCENTRATE BINS

plant. Yet it appeared logical and was done. The undoubted economies of the new plant were abundant water power, cheap coal, and greatly reduced freight on copper over the 55 per cent matte previously shipped. The installation of a converter department had effected great economies, since large sales of Montana matte in Liverpool were made at 10c. per lb. of copper when Lake was commanding 15, the seller losing all silver under 30 oz. per ton. In order to save the silver lost in Eastern refining, the construction of a 1,000,000-lb. electrolytic refinery costing about $250,000 was rushed to completion after the smelter commenced operation. This consisted primarily of a low brick building 110 by 174 ft. in dimensions, containing 228 tanks. Low voltage electric current was generated by three 180-kw. multipolar Thompson-Houston machines driven by a pair of 39-in. wheels, and transmitted over 22½-in. copper wires. Later, when the capacity of the refinery was increased to 3,000,000 lb., power was generated by a pair of 66-in. wheels direct-connected to two 4500-kw. 220-volt direct current generators, and the power delivered some 2000 ft. over a pair of heavy copper barlines, supported on a low wooden trestle. A furnace-refinery building

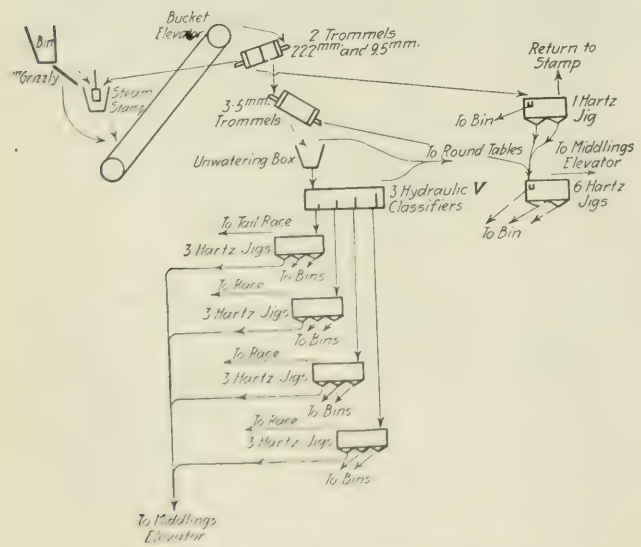

FIG. 6. STEAM STAMP SECTION, 1894

of iron with two small coal-fired reverberatories for refining cathodes, and a number of small auxiliaries completed the installation. This refinery operated quite successfully from the start, handling 50 per cent more metal than the original plans.

Extra converters and a Tod blowing engine were installed to handle Butte & Boston matte in the middle of 1893. The concentrator flow sheet was also altered somewhat in the fall of 1893, when the hutch concentrates from the finishing jigs and also from the tables and vanners were settled in small tanks in the lowest part of the mill, as sketched in Fig. 5. The overflow was elevated to a bin in the upper part of the mill holding coarser concentrates in the hope that the slimes might be filtered out. The cups from the third row or 2.5-mm. jigs were regarded as a middling, while the second hutch product was also sent to the elevator and recrushed; tailings from these jigs went directly to the river. High silica products were also recovered from corresponding portions of the last row of jigs, treating recrushed middlings, but this material was sent to concentrate bins because there was not fall enough to get them back into the elevator. A steam stamp section, with the flow sheet about as shown in Fig. 6, was also installed in the concentrator. This was seldom used, however, on account of the large amount of fine slime it produced, being regarded as a spare to operate only

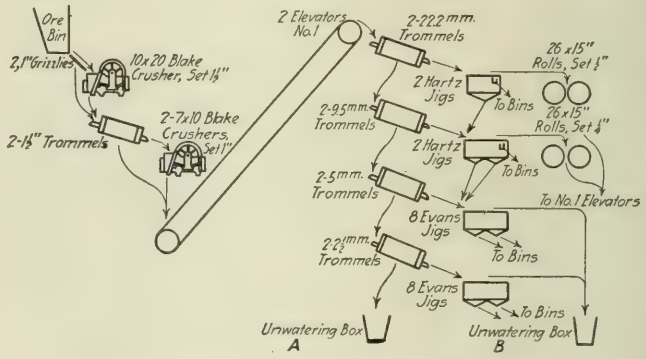

FIG. 7. COARSE CONCENTRATE DIVISION, 1897

during bad breakdowns in the roll sections. I believe it was in existance until 1897, however, when the third crusher and roll section used this part of the building, a new middlings section being installed in an annex. The steam stamp still exists and does yeoman duty, however, being converted into an air-operated hammer for the blacksmith shop.

A Blast-Furnace Found Essential

Smelter operations during 1893 quickly impressed Mr. Klepetko with the fact that blast-furnaces were urgently needed. Much ore was being delivered to the plant containing 40 to 50 per cent copper which could not be concentrated, and if sent to reverberatories, had to be finely crushed before it would satisfactorily roast and deliver a hot calcine. A mountain of converter slag had also accumulated with little promise of recovering the 2 to 5 per cent copper contained. In addition to all this, fine crushing second-class ore caused much sliming and high mill tailings. Coarse concentrates to be smelted in blast-furnaces would remedy these crushing troubles, and even if they were not of very high grade it would be best for the entire system to remove them early in the game. Consequently two small blast-furnaces were erected in a light building placed near where the present

blast-furnaces are, but in order to economize on excavation, set at an angle with the main smelter building as shown in Fig. 2. At first, matte from a small forehearth was cast from time to time in molds, broken and remelted in reverbertory furnaces. Soon larger settlers were built, and a matte ladle car hauled the liquid to a point under the converter craneway. These blast-furnaces were running early in 1894 and gave great satisfaction, bringing operations to a point where abandonment of concentrating and smelting in the Butte properties was justified. Mr. A. T. Elliott was engaged by Mr. Klepetko to take charge of the blast-furnace operations, coming with a crew of experienced furnace men from Argentine, Kansas—then a very important lead smelting center! Mr. Elliott was thereafter closely and honorably connected with the metallurgical operations for over twenty years, acting as general smelter foreman for a large part of that time.

Mr. W. J. Evans also arrived from Michigan at about the same time, to become mechanical superintendent. He, however, gave almost his whole attention to the mill, which now of course had to be remodelled to produce the necessary coarse concentrates for the blast-furnaces.

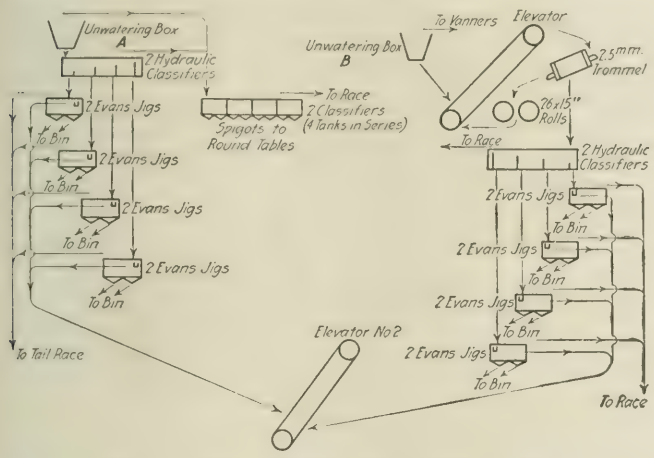

FIG. 8. FINE CONCENTRATE DIVISION, 1897

More attention was also given to the recovery of values from low grade middlings: the final result of a gradual change was the flow sheets given in Figs. 7 to 9 operating in the original wooden building. Briefly, the first coarse jigs were replaced by 2-compartment Hartz jigs and the crushing size increased from ½ to ¾ in. (later to 1¼ in. when two one-compartment bulljigs were installed for this coarsest material). Screen sizing was installed in place of hydraulic classification wherever possible in order to avoid the addition of such large quantities of water. Middlings were roll-crushed as before, but a "middlings-section" was later added owing to the fact that the tails from the middlings jigs were too rich to throw away. No tailings were allowed to go to waste coarser than 3 mm., but even then they would carry a considerable amount of metal—especially the jig tailings would run up to 1.5 per cent copper, while vanner tailings would run as high as 1 per cent. Jig tailings were therefore recrushed in Huntingtons, classified, and concentrated on fine jigs, round tables and Frue vanners (Fig. 9). During this time Mr. Evans also developed the so-called Evans jig, which was almost universally used on Butte ores for over ten years. This improvement was made by changing the rocker arm motion of the Collom jig to a rectilinear motion from an eccentric operating between two horizontal bars. This motion was put on the old Collom hutches, the plunger area being modified correspondingly.

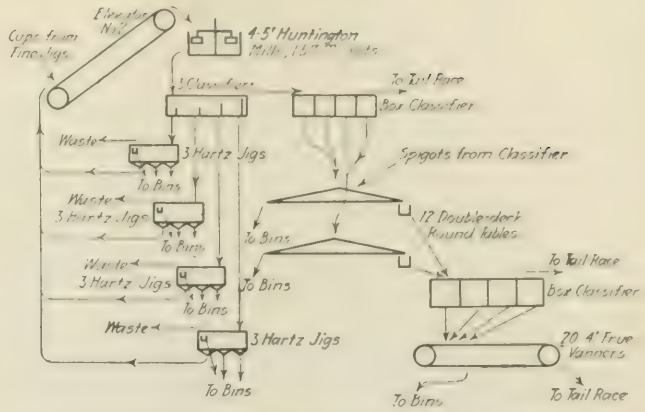

FIG. 9. MIDDLINGS DIVISION FOR THREE CONCENTRATOR SECTIONS, GREAT FALLS MILL, 1897

From my note book Table I on concentrator operation during 1894 may be interesting and worth recording. The ordinary operating labor (11 and 13-hr. shifts) per day was one foreman, two assistant foremen, two oilers, two rollmen, 16 jigmen, 2 tablemen, 2 vannermen, 2 cleaners, 2 carpenters, 2 firemen, 1 machinist, 2 machinist helpers, 1 pipe fitter, 2 tankmen, 1 slimer, 1 roustabout, 8 to 10 extras on a 10-hr. day shift for helpers, special changes, new construction and repairs.

Conclusion

By the beginning of 1894, therefore, the new plant was operating very nicely. The company's report showed that the Great Falls work had cost a total of about $2,100,000 and that the cost of copper had been reduced to about 8c. per lb. (a reduction of about 1c. over the previous year) with an average selling price of 9.2c. During that year some 4.7 per cent copper ore had been mined and sent to Great Falls—the lowest grade ore in Butte copper history! The average content was near 7.5 per cent—about 500 tons daily. Dividends were resumed a few months later, and the company entered on its phenomenal career as a money maker. During 1894 two more blast-furnaces were added, one of which was resmelting Butte & Boston matte. These first furnaces were replaced three years later by the present blast-furnace installation—which, by the way, has probably now smelted its last charge.

TABLE I. CONCENTRATOR DATA, 1894.

Capacity of concentrator, 2 sections at 250 tons per section.
Water used, 240,000 gal. per hr. for 500 tons.

Power:			
Rope transmission to drive machinery			500 hp.
Pumps			175 hp.
Electric lights			15 hp.
Total			690 hp.
Speed of machinery:			
Rolls	50 r.p.m.	Collam jigs;	
Crushers	300 r.p.m.	1st, 2nd, and 3rd row	125 r.p.m.
36 in. trommels	20 r.p.m.	4th row	130 r.p.m.
Hartz jigs	140 r.p.m.	Slime tables, 1 revolution in	1.5 min.
Slide-arm jigs	140 r.p.m.	Elevators, 300 to 400 ft.	per min.
Cost in 1894:			
Tons concentrated			170,000
Labor, (average crew 52½ men per day) or $3.10 per shift			$59,349
Supplies, (castings, shells, screens, belts, lumber, and hose)			34,336
Concentrate, handling and transfer			6,863
Boiler house expense (heat and reserve power)			5,120
Shops (machining and smithing)			1,911
Power house and transmission (maintenance of wheels, pumps, and generators) or $11 per hp. yr.			7,558
Miscellaneous operating account			4,297
Unloading ore, overhead, and other distributable expense			11,920
Total cost for 1894			$141,360
Less construction accounts			9,464
Net concentrating expense or about 72c. per ton			$121,896

Lowest monthly cost, 53c. in June.
Highest monthly cost, 94c. in January.

Legal Notes

By Wellington Gustin

Inspection of Potash Crystals Before Payment and Ex-Dock New York Construed

IN AN action to recover for damages claimed to have been sustained by reason of defendant's breach of a contract to deliver certain crystal chlorate of potash, the defendant set up a counterclaim for damage for the breach of a contract to deliver certain soda ash. Both the complaint and counterclaim were dismissed and both plaintiff and defendant appealed. (B. Brown & Bros. vs. Raritan Chemical Works, 177 N. Y. S., 309.)

The complaint claims an agreement was made between the parties by which the defendant was to sell and deliver to the plaintiff 300 kegs of crystal chlorate of potash at 60c. per lb., immediate delivery, net cash. This agreement defendant failed to keep, according to the complaint. This agreement was entered into on Nov. 29. The defendant replied by introducing the sales memorandum of brokers who handled the transaction. This memorandum sets out the terms as "net cash against the delivery order. Shipment spot." Replying further, the defendant on Dec. 1 presented plaintiff delivery order for the potash crystals and demanded payment therefor. Acceptance by plaintiff was refused without an inspection of the potash crystals, then in a warehouse at Jersey City. The defendant, at plaintiff's request, issued a permit allowing the inspection. This permit reached plaintiff's office at 3:30 p.m. In an accompanying letter plaintiff was told that the goods would be held until 5 p.m., at which time if payment was not received the contract would be regarded as broken by plaintiff's act.

Question Before the Court

So it appears from the facts that the potash crystals were neither inspected by the plaintiff nor delivered by defendant, and the question therefore presented was whether plaintiff had the right, under its contract, to an inspection of the goods before being required to pay for the same. If it had such a right, then the question of whether the opportunity offered by defendant was a reasonable one was a question of fact for the jury, said the court. But the terms of the sale were net cash against delivery order, and those terms conclusively negative any idea that an inspection was to be allowed them. On the contrary, the court said, by agreeing to pay cash on production of the delivery order, plaintiff effectually waived any right to examine the goods. The act of defendant in offering plaintiff a privilege of inspection was a purely voluntary one, without consideration, and no new contract was created thereby, nor was any so claimed. Hence the court affirmed a dismissal of plaintiff's claim against defendant for failure to deliver the potash crystals.

Taking up defendant's appeal on its counterclaim: This claim arises out of a written contract between the parties for the sale of 24 carloads of soda ash at 2⅛c. per lb. ex-dock New York, net cash against documents, to be bought by plaintiff for defendant. The provision as to deliveries was as follows:

"Deliveries: Shipping instructions to be given by the buyer not later than 20th of the month next preceding the month of shipment. Two cars monthly over year 1917. Shipments from works from January to December inclusive."

None of the soda ash was ever delivered under the contract, as no shipping instructions were ever given by the buyer (the defendant) as required by the contract. The general provision was that shipping instructions were to be given by the buyer not later than the 20th of the month next preceding the month of shipment. The special provision was for two cars to be shipped monthly from the works, from January to December; and these shipments were to be made to whatever points the buyer fixed. The court held that under these conditions the seller was not bound to tender the soda ash to defendant at any particular point, but that the seller had the right to await the shipping instructions, and if these were not received, then to treat the failure to give them by defendant as a breach of the contract.

Said the court: This was not a case where the goods were to be delivered "f.o.b." at the City of New York, or at any particular place. They were to be shipped from plaintiff's works to such place as named by defendant. The clause "ex-dock New York" merely fixed the price as being at that point, in order to determine the responsibility for freight charges. Holding that defendant thus breached the contract, for which it was itself asking damages for subsequent breach of plaintiff, the court upheld the lower court's dismissal of defendant's counterclaim.

Damage During Transit Follows Title to Consignee

That the buyer cannot reject a shipment of goods on its arrival because of damage during transit, the goods having been sold f.o.b. point of shipment, has been held by the Supreme Court of New York in an action by the seller for the purchase price of the goods. It was held that title passed to purchaser by the bill of lading and deterioration in transit was a loss following the title which became vested in the consignee. (Derma-Viva Co., Inc., vs. Kells Co., 176 N. Y. S., 776.)

From the facts it appears that several months before the shipment of goods sued for the plaintiff had written defendant that its terms of shipment were to be "f.o.b. Chicago," and that claims for damages must be made to carrier. This particular shipment was so made on Dec. 19, in boxes marked "Keep From Freezing, Ship in Refrigerator Car." The bill of lading, with invoice, was received by defendant and retained about two weeks without objection. The goods arrived Jan. 5, but were frozen, and these shipping documents were returned by mail to the plaintiff. There had been delay in filling the order. It had been originally mailed to plaintiff's New York agent on Nov. 21, but the court found such delay was not a proximate cause of the damage to the shipment. Title passed by the bill of lading, the goods being sold f.o.b. Chicago, said the court. Defendant's secretary and manager held the shipping documents to await the arrival of the goods, and admits he would have accepted them, had the articles not been frozen. Such loss resulting in transit follows the title to the consignee, so that such a consignee cannot rescind the shipment, where the documents had thus been retained without objection. Hence a judgment for the defendant in the lower court was reversed with directions to enter judgment for the plaintiff.

Production of Copper From Secondary Material

Methods of Sampling Miscellaneous Products Entering the Refinery, Their Treatment in Regular or Special Furnaces, With a Discussion of the Commercial Possibility of Recovering Some of the Impurities as Metallic By-Products

BY LAWRENCE ADDICKS*

IN ADDITION to the circulating products incident to normal copper refining, the plant is often called upon to treat a wide range of metallurgical by-products from outside sources as well as miscellaneous copper-bearing scrap material. Now that matte smelting plants exist on the Atlantic seaboard, there is little reason to consider anything in the nature of ore or matte, but the following list of materials is fairly representative of what offers:

A. Junk.
  a. Lamps, clocks, etc.
  b. Borings and chips.
  c. Wire.
  d. Sweepings.
  e. Coins and alloys.
B. Mill Products.
  a. Wire.
  b. Scale.
  c. Cement.
  d. Stampings.
C. Metallurgical Products.
  a. Cement.
  b. Amalgamation plates.
  c. Secondary pig.
  d. Nickeliferous pig, black copper, etc.
  e. Furnace bottoms.
D. Refinery By-Products.
  a. Silver refinery slags.
  b. Liberator tank cathode products.
  c. Flue products.

There is a suprisingly large tonnage of such miscellaneous material available, and of course a good deal of it is absorbed by relatively small sweep smelters, who generally feed it indiscriminately into a small blast-furnace, making a foul pig which is sometimes given an additional reverberatory treatment and sent back to the market as casting copper and sometimes is sold to an electrolytic refinery. Such work is a very disturbing element in a copper refinery unless the tonnage accepted is great enough to warrant the establishment of regular facilities for handling it. The general questions involved are, first, sampling; second, disposition; third, proper furnace construction; fourth, possible saving of impurities as by-products.

SAMPLING

The sampling of junk is an art in itself. The ordinary junkman, who travels around in a wagon buying what offers, learns in time to make very close estimates of the metal values of such material, but the refinery cannot afford to let its sampling department adopt such methods on general principles.

The first rule in sampling junk is to classify the material. The insulated wire is put in one lot, the bare wire in another, the alarm clocks and automobile lamps in a third, the sweepings in a fourth, the borings in a fifth, and so on. Clocks and lamps have been considered as a class because they are one of the staples of the junk business. Occasionally large lots of Oriental bronze coins come into the market. A noteworthy instance of this was when Japan took over the control of Korea and exported about 6,000,000 lb. of Korean "cash."

The second step in the sampling is to endeavor to get a representative part of each classified pile. Coins or sweepings can be quartered down like so much crushed ore. Wire can be clipped here and there. Borings can be reasonably sampled by selection. The remainder can be handled only by intelligently taking grab samples, and this requires experience and skill.

The third rule is always to take duplicate samples and to hold the lot intact until assays are out, giving an opportunity for resampling if the assays show sufficient lack of agreement to indicate poor sampling.

The next step varies according to the nature of the material. With dirty metallic material, such as wire or borings or sweepings, a burning loss should be obtained by soaking with gasoline where necessary and igniting, noting the weight before and after. With miscellaneous manufactured material, where different metals are used, as in a clock, or containing solder, as in a teapot, the only way is to make a crucible melt of a rather large sample, accounting for the bar, slag and crucible absorption. Often a material has to be sorted into metallics and dust, as in the case of some sweepings. In general, therefore, it will be seen that sampling junk is a tedious and expensive business. Most junk carries some gold and silver values arising from jewelers' sweeps, etc.

Mill products, such as scrap wire, punchings, etc., shipped directly from the wire mill or other factory to the refinery, are much easier to sample. Here the material is already classified and relatively clean. Care must be taken to see that no bimetallic wire has inadvertently found its way into straight copper wire bundles. It would be thought that bright copper wire from primary sources would need no sampling, but there is always more or less grease attached to it, and the true copper content is nearly always several tenths of 1 per cent below standard. Tinned wire will run 1 per cent or more low and bimetallic wire may run 40 per cent low. The refinery in turn makes a small profit in that the wire bars sent out and accepted by the trade as 100 per cent copper in reality run seven or eight hundredths of 1 per cent below this.

Among the metallurgical products two require special mention, amalgamation plates and furnace bottoms. Amalgamation plates are copper sheets which have been amalgamated on the surface and used to collect gold and silver values from finely crushed native ores. The amalgam has been thoroughly scraped off before the plate is scrapped on account of wear or other defect, but nevertheless sufficient gold is retained to make such material relatively valuable. In this case it is necessary to shear the plates up into equal squares of a few inches on a side; then take systematically say every tenth

*All book rights reserved by the author.

square, following such a system of reduction until the sample is small enough to permit of crucible reduction.

Furnace bottoms are very troublesome to handle. They are generally received in large masses which cannot be drilled or broken. They are usually placed in a furnace for treatment by an overhead crane at a time when the roof is out for rebuilding. They cannot be blasted or cut apart and the only way to reduce the size of a large piece is to build a small flue across the top and channel with a hot oil flame.

The only way to sample them is therefore to chip around the edges. Unfortunately they are often quite rich, as silver and gold tend to concentrate in furnace bottoms. The refiner has to make an allowance in the treatment terms to cover the sampling danger when handling such material.

Disposition

There are several places in the process where secondary material can be introduced. The first is the slag cupola, the function of which is primarily to treat the anode and wire bar furnace slags and which always has capacity to spare. Nearly anything in the scrap line can be introduced here, but it does little more than extract the metals contained and put them into compact shape. Their chemical treatment requires oxidation, which cannot be obtained in the strongly reducing atmosphere of a black copper cupola. Plants treating junk exclusively usually make a blast-furnace melting their first operation, using some briquetting or sintering apparatus to take care of the very fine material before charging.

The usual point of entry is the anode furnace. This insures saving the silver and gold contents and getting the copper in electrolytic form, neither of which is possible to the small junk smelter.

There are certain objections to introducing such material into an ordinary anode charge. In the first place, it is usually in such shape physically that it will take up a disproportionate amount of space in the cold charge. This can be met to a certain extent by charging it at the recharge period when there is plenty of room in the furnace. Then impure material delays the blowing and skimming, and it is important that the furnaces operate on schedule time. Finally, quicker work and better elimination of impurities as well as a better slag concentration for possible by-product recovery are made by treating impure material without dilution. This leads to setting an anode furnace apart for special work at least part of the time. This has another great advantage in that it allows direct costs of the work to be kept.

Then we have the refining or wire bar furnaces. Nothing should be added to a cathode charge regarding which there can be any question as to quality. It is customary to include as admissible, however, scrap wire baled in "cabbages" which originates at standard wire mills. In ingot charges, where conductivity requirements are not quite so strict, liberator cathodes from the first row of tanks in the purifying system may be added with discretion.

Finally, we have the possibility of using a special refining furnace for the production of casting copper. This is attractive in that it enables material which is practically free of silver and gold and high in copper—scrap brass for example—to be worked directly into a marketable product. The disadvantage is that casting copper has no stable market. It always sells at a discount and at times is nearly unsalable.

Until recent years the standard refining reverberatory has been constructed of silica throughout. In some special cases a silica brick bottom has been employed, but the usual construction was silica sand bottom with silica brick sides and roof. Such a furnace is built with a cooling vault, cast-iron bottom plates mounted on brick piers, and a false bottom of fire-clay brick. The vault should be arranged with consideration of a possible run-out of copper through the bottom. It is desirable to lead the molten copper away from the vault before it sets, so that it can be recovered without tearing down the entire furnace, but it is equally essential to see that it does not run into the casting wheel pit or ash pit, where it will probably come into contact with water and cause serious explosions. When a break-out occurs the only thing to do is to charge cold copper into the furnace to set the charge, which is not difficult on account of the high heat conductivity of copper; but if explosions are occurring it is not safe to approach the furnace.

A sand bottom must be carefully impregnated with copper, and an excellent way in which to accomplish this is to mix the sand with about 30 per cent of its weight of copper oxide scale. This is thoroughly turned over and shoveled into the previously dried furnace, where it is calcined at a moderate heat for about 12 hr. The fire is then dropped and the floor carefully leveled and tamped down. The furnace is then fired at maximum temperature—perhaps 2700 deg. F.—for 24 hr. and the furnace after cooling is ready for a small seasoning charge of scrap wire or similar light material. This charge, amounting to perhaps 10 per cent of the rated capacity of the furnace, is melted and ladled out, and after another brief cooling, one twice as large is put in. After this has been ladled the furnace should be ready for service, although it should not be crowded for a few charges, starting at 50 per cent capacity and working up.

This furnace, even when treating high-grade material, will be more or less fluxed by the cuprous oxide of the charge, the silica of the slag being taken chiefly from the bottom of the walls near the metal line. The old treatment for this was "fettling," or plastering corroded spots with fire clay, after each charge was cast.

Prolonged heating in the treatment of foul charges is apt to smelt some of the bottom of the furnace, and when pieces of the bottom begin to "float up" there is always danger of a run-out. Also if elements such as lead are present in appreciable quantity the litharge formed will hungrily attack the silica of the furnace. In fact, a good silica furnace can be easily ruined by a single charge of leady copper. More than 2 per cent lead is always cause for great anxiety.

After a while magnesite and chrome brick were tried as a lining material for the walls of the furnace near the metal line. Approved practice was the use of magnesite for the zone protected and the introduction of one course of chrome brick between the magnesite and silica of which the wall was continued up, the chrome acting as neutral material between the basic and acid bricks.

Magnesite brick spalls badly when exposed to sudden temperature changes. Chrome brick is not subject to this objection, but fails because of softening when exposed to heavy thrust when highly heated.

The next step was to use a chromite verb with great gain in heat control of the furnace, since small dimensional changes from the cutting away of the verb cause great differences in the characteristics of a furnace.

Then the complete basic furnace was developed with magnetic bottom and chrome walls and roof. (Addicks

and Brower, U. S. patents 1,083,719 and 1,148,814.) The sand bottom furnace is constructed with the bottom inside the walls; the basic brick furnace is built with the walls standing on the bottom in order to carry the thrust of the inverted arch directly through to skewbacks reacting against the brickstaves.

With complete basic furnaces it has been found possible to treat material high in lead, and which may require heavy firing for several days without damage to the furnace, so that clean anodes may be made from foul sources of supply.

By-Products

Tables I and II give an idea of the character of some of the low-grade material offering in quantity.

An examination of these analyses shows that aside from copper, the main value, there are often present considerable quantities of gold, silver, nickel, cobalt, lead, zinc and tin. Where gold and silver are present in sufficient quantity to pay the cost of electrolytic treatment, the furnace product should obviously be anodes. Where the silver and gold values are low, casting copper may be considered as a product, but the time required for refining, market deduction for casting copper, values and costs must be carefully balanced in making a decision.

TABLE I. ANALYSES OF CEMENT COPPER

Source	Oz. Gold	Oz. Silver	Per Cent Copper	Per Cent Iron	Per Cent Insoluble
United States	Trace	3.6	80.93	1.40	8.80
United States	0.01	5.3	71.53	1.30	17.06
United States	0.28	11.0	60.58	10.00	1.68
Australia	0.45	0.32	78.28	3.97	3.50
England	0.05	19.8	76.62	5.20	1.63
Belgium	Trace	0.40	69.51	8.50	2.24
Unknown	Trace	0.20	32.18	26.02	5.99

When any of the other impurities are present in quantity, we may consider the possibility of their recovery in slags, in flue products or through the electrolyte purifying plant. In the formation of slags the elements oxidize in the order of their basicity. Their relative affinities for oxygen may be judged by the heats of formation of their common oxides, as follows:[1]

Au_2O_3	−11,500	CoO	+ 64,100
Ag_2O	+ 7,000	FeO	+ 65,700
CuO	+37,700	ZnO	+ 84,800
PbO	+50,800	SnO_2	+141,300
NiO	+61,500		

From these figures we should expect to get first the tin, then the zinc, then the group of cobalt-nickel-iron, and finally the lead, leaving copper-silver-gold in the metal bath. In practice, however, we have to consider the fusibility of these oxides and the readiness with which they form silicates. The situation is quite different from ore smelting in that we are dealing with metallic alloys and always in the presence of a preponderating amount of copper.

The possibility of recovering tin from secondary copper such as given in Table II is indicated in Table III.

[1]Values from Richards' "Metallurgical Calculations."

TABLE III. TIN RECOVERY

Input

Material	Weight	Per Cent Sn	Contents
Fine bullion	53,567	3.19	1709
Fine bullion	50,874	3.30	1679
Fine bullion	61,125	2.07	1265
Fine bullion	51,918	2.23	1158
Fine bullion	54,027	2.10	1135
Fine bullion	54,440	3.02	1644
Furnace returns	6,000	0.27	16
Anode scrap	30,000	0.15	450
Total	361,951	....	9056

Output

Material	Weight	Per Cent Sn	Contents	Per Cent Sn Input
Anodes	178,801	0.61	1701	18.8
First slag	7,686	0.38	29	0.3
Second slag	17,796	0.78	139	1.5
Third slag	39,657	14.43	5722	63.2
Metallics	4,019	0.61	25	0.3
Unaccounted for	13,992	.....	1440	15.9
Total	361,951		9056	100.0

There has been collected in the third slag 63 per cent of the tin. If we take the copper in this slag at 25 per cent, we shall have upon reduction to metal a foul alloy running 30 to 35 per cent in tin, a reasonable first step toward the recovery of this metal.

Zinc is not a sufficiently valuable metal to warrant the cost of its extraction from impure or low-grade products. Inasmuch as a copper furnace is operated at a temperature above the boiling point of zinc, it would be possible to make a certain recovery as fume, but as this would be contaminated with other volatile impurities such as arsenic and antimony present in foul bullion, such an operation would have no commercial standing.

While iron, cobalt and nickel stand close together in the heat of oxidation scale they show a marked difference in slagability. In fact the ease of removal in a reverberatory furnace might be arbitrarily indicated as 1.00 for iron, 0.10 for cobalt, and 0.01 for nickel.

TABLE IV. RELATIVE SLAGABILITY OF IRON, COBALT AND NICKEL

	Original Bullion	After First Refining	After Second Refining
Copper, per cent	94.55	99.42	99.66
Iron, per cent	3.04	0.011	0.008
Cobalt, per cent	0.894	0.023	0.024
Nickel, per cent	0.408	0.110	0.109
Iron	1.000	0.004	0.003
Cobalt	1.000	0.026	0.021
Nickel	1.000	0.270	0.266

This is illustrated in a general way by some published[2] data of experiments conducted in a 2-ton furnace at the Wysk smelter in Russia, some of the results of which are shown in Table IV.

Iron is of course far too cheap a metal to be considered as a by-product except in very large-scale ore smelting operations. It can be easily removed from copper bullion by slagging, but not without the corresponding renewal of a small amount of the copper as cuprous oxide, which forms the scorifying agent.

Cobalt can be removed with reasonable facility in

[2]Hofman's Metallurgy of Copper, p. 391.

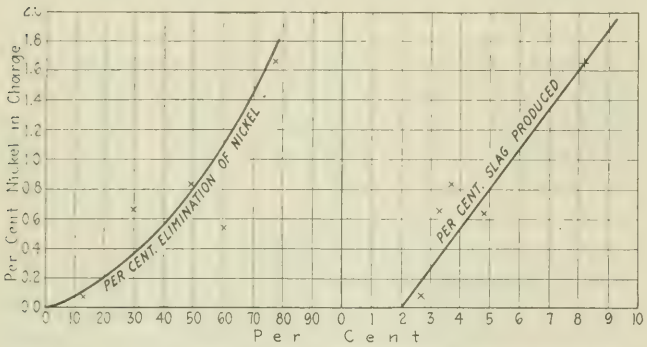
like manner and collected in a slag running perhaps 20 per cent cobalt and 20 per cent copper, but really cobalt-free copper could not be produced without slagging a large amount of the copper in repeated scorifications.

Nickel is much more difficult to deal with, and is generally recovered by separation as a soluble sulphate in electrolytic refining. Considerable data are available on its behavior in the anode furnace. An example of



BEHAVIOR OF NICKEL IN THE COPPER REVERBERATORY

some large-scale experiments is given in diagrammatic form in the illustration, and these curves are analyzed in Table V.

TABLE V. BEHAVIOR OF NICKEL IN THE COPPER REVERBERATORY

	Per Cent				
Nickel in charge	0.0	0.5	1.0	1.5	2.0
Elimination	...	37	57	72	81
Nickel in product	0.0	0.32	0.44	0.45	0.40
Slag	2.0	3.8	5.7	7.6	9.4
Nickel in slag	0.0	4.9	10.0	13.8	17.1

It is evident that more prolonged working of the charges richer in nickel would result in a somewhat lower nickel in the product and a larger quantity of slag lower in grade as to nickel, but it is quite out of the question to reduce the nickel tenor of a large charge to the degree shown by the small Wysk furnace. The slag, if treated in a matting furnace for the recovery of copper, will lose a large part of its nickel to the new slag; if treated in a black copper cupola, the nickel will be nearly all reduced with the copper.

Lead is readily separated from molten copper as litharge. As this active base rapidly attacks siliceous material, quite small quantities of lead demand a basic furnace for safe handling. Lead is practically insoluble in pure copper, but in the presence of sulphur or various impurities it is absorbed, and considerable quantities are found in secondary copper and occasionally in blister where leady copper ores have been treated. Certain bearing metals are made of a mixture chiefly of copper and lead, and the black Korean coins listed in Table II showed high percentages of lead. When melting down large quantities of these in a furnace with a basic brick bottom placed over a cooling vault, it was noticed that practically pure lead sweated through the bricks underneath, indicating liquation and a possible means of separating lead from copper. A copper-lead slag which can be profitably smelted for both metals is readily made from such material.

In general, electrolytic refineries recover a large part of any nickel or lead entering their plants in sufficient quantities, and steps would be taken to recover cobalt and tin did the crude copper carry sufficient of these metals, but the disturbance of the process due to interference of these impurities in the main business of copper refining overshadows the possibility of placing impurities on a revenue-producing basis except where large regular quantities have to be dealt with. Where casting copper is made, a portion of these alloy impurities remains and actually improves the copper for certain purposes by increasing its fluidity or altering its color.

The Absorption of Gases in Spray Systems and Towers

By Edwin M. Baker

IN PROBLEMS involving the absorption of a gas by a liquid it is generally desired to absorb or dissolve some one constituent of a gas mixture by the liquid. It will be found convenient to call the gas to be absorbed or dissolved simply the "gas," and the gas mixture containing this gas and other diluting gases the "gas mixture." The absorption of gases in liquids may be divided into three subdivisions of a general class, in which most absorption problems will fall. First, the case where the nature of the gas and liquid is such that a chemical reaction takes place so that the gas will not exert any appreciable vapor pressure after absorption. The absorption of ammonia gas in an excess of sulphuric acid would be an example. Second, the case where the nature of the gas and liquid is such that a chemical reaction takes place, but the compound formed is sufficiently unstable so that the dissolved gas exerts an appreciable vapor pressure. The absorption of ammonia gas in water would be an example. Third, the case where no chemical reaction takes place between the gas and liquid, and where the liquid exerts a vapor pressure directly dependent on the amount of absorbed gas. An example of this is the absorption of the so-called gasoline content of natural gas in heavy mineral oil. Different combinations of gases and liquids may be found which will give a series of conditions gradually shading from the first to the third subdivision. In this general class, then, are included the cases where simple or no chemical reactions take place. It does not include complicated reactions such as take place on the introduction of oxides of nitrogen with excess oxygen in the form of air into absorption towers; where water is used as the absorbing agent to form nitric acid; and where the oxidizing of the lower oxides of nitrogen must be taken into account.

In the general class considered, if the gas mixture and liquid were put in a closed container and left a sufficiently long time, the liquid would absorb the gas until the vapor pressure of the dissolved gas just equalled the partial pressure of the gas in the gas mixture. In case 1 this would be 100 per cent absorption, because the dissolved gas would exert a zero vapor pressure. Hence the partial pressure of the gas in the gas mixture would be zero, and the per cent gas would be 0 per cent. Since the volume of gas divided by the volume of gas mixture equals the partial pressure of the gas divided by the total pressure, then the per cent of gas in the gas mixture equals

$$\frac{\text{partial pressure of the gas}}{\text{absolute pressure of the gas mixture}}$$

In cases 2 and 3 the per cent absorption would be something less than 100 per cent, depending on the nature of the gas and liquid. Suppose we express the nature of the gas and liquid by calling the theoretical percentage absorption, when the liquid and gas are in intimate contact for a sufficient time, at some imaginary standard con-

ition, K. The theoretical absorption under some other ondition may be called K'. Then K' may be increased (if t is not already 100 per cent) by increasing the total ressure on the gas mixture, since this increases the par- ial pressure of the gas, and hence the vapor pressure of he dissolved gas necessary to re-establish equilibrium. And the latter means increased concentration of the issolved gas. Lowering the temperature of the system ill in general increase K', since lowering of the tem- erature gives a lowering of the vapor pressure of the issolved gas. Increasing the concentration of the gas n the gas mixture will in general increase the amount of as absorbed, since the partial pressure of the gas in- reases in proportion to the per cent composition. Lower- ng the concentration of the dissolved gas in the liquid ill decrease the vapor pressure of the gas, and so ncrease the amount of gas that will dissolve. The value f K' can be found in the literature for most gases and quids. Or, at least, information may be found from hich a working value of K' may be obtained. Fig. 1 ives various values of K' at 60 deg. F. and 30 in. arometer, for certain concentrations of ammonia in the as mixture and liquid. A family of such curves would e required to express K' for all conditions.

Rate of Absorption

This, however, does not tell us anything about the ate of absorption under any given conditions. In eneral, it may be said that the force which causes a as to be absorbed by a liquid is the difference between he partial pressure of the gas in the gas mixture and he vapor pressure exerted by the gas dissolved in the quid. With no difference the rate would be zero, nd in order to get a rapid absorption of a gas in a quid it must be understood that theoretically perfect bsorption cannot be expected, that is, some difference n partial and vapor pressure must be allowed for.

The rate of absorption also depends on the intimacy f contact between the liquid and gas mixture, and this epends on the design and operation of the particular bsorption tower or spray system.

The per cent of the theoretical absorption realized epends on the rate of absorption and the duration of ontact of the liquid and gas mixture, the latter also epends on the design and operation of the apparatus.

To sum up, the rate of absorption, R, for a given gas nd liquid will be proportional to the product of the ifference in partial and vapor pressures, D, times a actor expressing the intimacy of contact, I, or $R = DI$. The per cent of theoretical absorption, A, will e proportional to the rate of absorption times the time f contact T, or $A = C_1DIT$, and the actual absorption or any gas and liquid will be proportional to K' times , or actual absorption, $P = C_2K'DIT$.

This formula is not capable of any direct mathe- natical application, but may be useful in comparing arious systems working on different gases and liquids, r for analyzing certain absorption problems. C_2 is the roportionality constant, depending on the units in hich the other factors are expressed, etc. K' is the heoretical absorption under the particular temperature, ressure and concentration of entering and exit gas ixture and liquid employed. K' will generally be fixed y plant operating conditions, and may be varied only y changing these. D, the difference in partial and apor pressures, depends on these plant conditions; and lso on the design of apparatus, in that for a given concentration of gas in the exit gas mixture and liquid, and for a given concentration of the entering gas mix- ture, D will have the effect of being larger with the counter-current flow principle than with parallel-current flow. The effective value of D with counter-current flow will depend on the number of spray systems or towers in series and on the number of effective zones in each unit. I and T will depend on the design and operation of the system as a whole. Increasing the liquid flow or circulation rates will in general increase I, the intimacy of contact, while increasing the volumes of gas mixture handled will decrease both I and T. This formula may be especially useful if a particular system is being used under known conditions and it is desired to know what it, or a duplicate system, will do under different conditions, say using a different gas and liquid. If the same conditions of flow rates of gas and liquid are to be maintained, the formula reduces to (1) per cent of absorption, $P_a = C_3K'_a$, and likewise (2) $P_b = C_3K'_b$, where the subscripts refer to operation under known or desired conditions. Substituting in (1) the

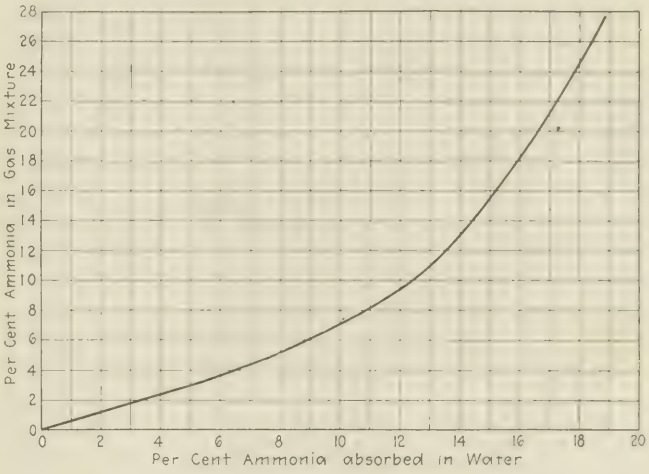


FIG. 1. CONCENTRATION OF AMMONIA IN GAS NECESSARY TO GIVE SOLUTION OF STRENGTH SHOWN. THEORETICALLY PERFECT ABSORPTION

known values will give a value for C_3. K'_b may be found from plant or published data. Then the product of C_3 times K'_b will be the per cent absorption under the new conditions. Now suppose it is desired to use some other conditions of flow rates of gas and liquid. If the effect on the per cent absorption of varying these two factors is known for any fixed K', when this is less than 100 per cent, then the K'_b we have obtained may be corrected to correspond. The results so obtained should be sufficiently accurate to act as a real guide in making new installations or to show plainly if some of the towers or systems in use are not giving the proper absorption, due to faulty construction or operation, or to offer a comparison of the capacity and efficiency of widely different systems.

The writer recently made some absorption tests using the spray system for liquid cooling.

Ammonia gas, from cylinders of liquid ammonia, mixed with air, was used as the gas mixture, and city water was used as the absorbing liquid. The per cent of ammonia in the exit liquid and in the entering and exit gas mixture was determined, and the temperatures of the entering and exit water and gas were taken, as well as data to compute the rate of flow of water. The rate of flow water and all temperatures were held

practically constant, while the volume and percentage composition of gas mixture were varied. The composition of the exit gas mixture and water varied as a result of this. Fig. 2 shows the per cent ammonia in the exit gas mixture plotted against the per cent ammonia in the exit water from the spray system, as compared with the amount that would be found for theoretically perfect absorption. At first sight the relative value appears very large, but it should be remembered that the amounts involved are very small. The data shown here are important only in that they show that the per cent ammonia in the exit gas is largely determined by the per cent ammonia in the exit liquor. The curve for theoretical absorption is nothing more than values of K', and since the absorption obtained is proportional to this, it follows that the absorption is taking place according to definite laws, and is not haphazard. If such a relation is found not to exist in any absorption tower or other system, it would be advisable to investigate the tower filling or distribution of absorbing liquid for effective channels where gas is getting by without being acted on. Fig. 3 shows the total percentage of ammonia recovered by absorption plotted against the volume of gas mixture handled. In this spray system, and presumably in others, this was found to be one of the most important variables in operation. Increasing the volume of gas decreases the intimacy and time of contact, and so, other things being equal, naturally decreases the total absorption.

The increasing of the percentage of ammonia in the entering gas increased the percentage of total absorption in terms of the theoretical. The effect was small enough, however, to be nearly hidden by other variations in the test conditions.

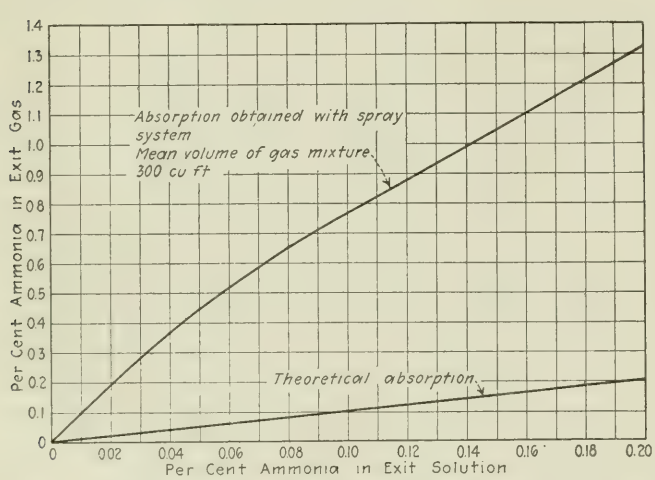

FIG. 2. PER CENT OF AMMONIA IN THE EXIT GAS AND SOLUTION FOR ABSORPTION OBTAINED WITH SPRAY, AND THEORETICALLY PERFECT ABSORPTION IN WATER

The flow of water used was such as to give nearly maximum absorption, and the rate of flow was not varied. The curves given are of general importance only in that they may be duplicated for existing installations, and comparisons drawn. In this case the curve in Fig. 3 shows practically the per cent absorption in general operation for this particular system, with flow rates of liquid of about 30 gal. per min. It is practically a series of values for $C_2K'DIT$, and since, according to the composition of the exit water reached, the theoretical absorption should be 99.8 per cent $= K'$, the curve practically gives values of C_2DIT. In other words, if a given volume of any gas is to be absorbed in any liquid, from the curve in Fig. 3 can be obtained the absorption that may be expected for the volume of gas handled; i.e., for 300 cu. ft. per min., this machine would give 75 per cent of the theoretical absorption. This is the value of C_2DIT. Now, if the temperature and concentration of the exit liquid and entering gas are to be such that only 80 per cent of the gas may be theoretically absorbed, the value of K' will be 80 per cent. The actual absorption that will be realized will then be 75 per cent of 80 per cent = 60 per cent of the gas in the gas mixture. Suppose the gas mixture originally contained 50 per cent of the gas to be absorbed, or 150 cu.ft. Of this 60 per cent, or 90 cu.ft., will be absorbed and 60 cu.ft. will pass through. The exit gas mixture then has a volume of 6 + 150 = 210 cu.ft., and contains 60 ÷ 210 = 28.6 per cent gas.

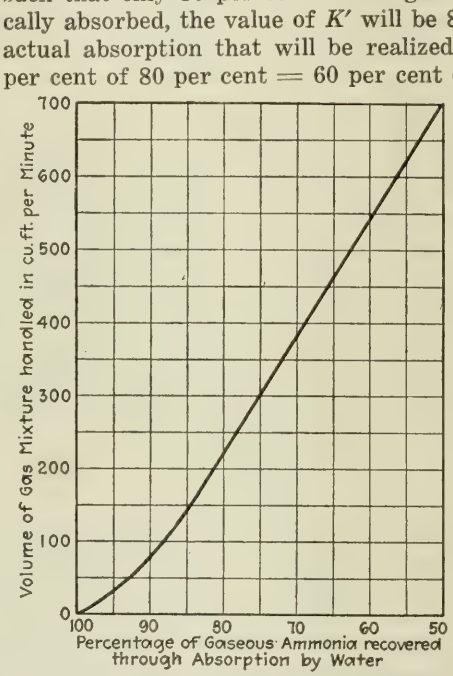

FIG. 3. RELATION BETWEEN VOLUME OF GAS MIXTURE HANDLED AND PERCENTAGE RECOVERY OF AMMONIA

Suppose this exit gas is passed through a second spray system, counter-current flow of liquid and gas mixture being used. Also, to simplify the problem, assume K' to remain unchanged, though in general it would increase in the successive spray systems. For 210 cu.ft. per min. the absorption would be 80.5 per cent of the theoretical, or the total absorption would be 80.5 per cent of 80 per cent = 64.4 per cent. The absorption in the second spray system is then 64.6 per cent of 60 cu.ft. = 38.6 cu.ft. The total absorption in two sprays is then 38.6 + 90 = 128.6 cu.ft. or 128 ÷ 150 = 85.7 per cent of the gas.

The exit gas from the second spray contains 150 cu.ft. of diluting gases and 60 — 38.6 = 21.4 cu.ft. of gas. This gives 150 + 21.4 = 171.4 cu.ft. of gas mixture, containing 21.4 ÷ 171.4 = 12.4 per cent of gas. Suppose this gas to be passed through a third spray system, counter-current principle. The absorption for 171.4 cu.ft. is 83 per cent of the theoretical, or the actual absorption is 83 per cent of 80 per cent = 66.4 per cent. The absorption in the third system is then 66.4 per cent of 21.4 cu.ft. = 14.2 cu.ft., making the total absorption in the three systems 14.2 + 38.6 + 90 = 142.8 cu.ft. and the recovery 142.8 ÷ 150 = 95.2 per cent. The results obtained are low, for a large volume of gas mixture was assumed, and in general the value of K' (which has been considered constant) will increase quite rapidly in the spray systems or towers having the more dilute exit liquid.

The last portion of this paper is subject to considerable elaboration, but this article has aimed rather at giving merely fundamental principles.

The Catalyst for the Oxidation of Ammonia*

escription of General Types of Equipment Employed for the Production of Nitric Acid by the Catalytic Oxidation of Ammonia—Platinum as Catalyst—Influence of Space-Time-Temperature Conditions—Conclusions

By G. A. PERLEY

THE methods involved in the production of nitric acid by the catalytic oxidation of ammonia have been described in a great variety of places. It eems strange to observe the tremendous variations in ie general types of apparatus employed in this work hen the basic feature must be the same for all uipments where platinum is used as a catalyst.

Some combinations used in commercial practice are:

Ostwald Catalyst

The use of a preheated mixture of air and ammonia rough a heat exchanger in accordance with Ostald's plans. Platinum sponge or nets were used as ie catalyst. A modification of this type has consted of a nickel tube, 8 ft. long by 2 in. diameter, in ie end of which was rolled a piece of platinum foil eighing about 1.6 oz. An enamel-surfaced iron tube rrounds this nickel tube and serves as the inlet for ie ammonia-air mixture. The hot gases passing wn the inside of the nickel tube transfer a portion their heat content to the cold ammonia-air mixre flowing up between the nickel tube and the amel-surfaced iron tube. It is reported that a temrature on the catalyst of from 600 to 800 deg. C. is tained with a 9 per cent (vol.) NH_3. Such a system quires the use of expensive enamelled iron and ckel, while the production per unit is necessarily nall. Again there is no temperature control on such system, and in actual practice there is a certain mount of pre-decomposition. A production of 164 . of nitric acid per day, or the equivalent of the idation of 45 lb. of NH_3 per unit, is the reported eld. This gives a capacity of only 28 lb. of NH_3 per . of platinum per day. It seems as if this capacity reported is somewhat low, yet it shows the ineffiency of the use of a solid sheet of platinum.

Kaiser Catalyst

A modification by Kaiser of Spandau has been deribed where heat control was obtained through the parate preheating of the air in a coke furnace to 00 deg. C., and then admixture of this with the amonia. Dr. Kaiser has claimed a preactivation of the itrogen of the air by this preheating. His claims of ecuring 200 per cent oxidation efficiency by this solled "autoxidation" have been proved most ridicous. While the catalyst of the Ostwald modification was usually some sort of thin foil, the Kaiser atalyst consisted of four platinum gauzes placed in ose contact with one another.

The gauzes were made of 0.0024-in. diameter wire nd 80 meshes per linear inch. A catalyst of 0.02 in. tal thickness resulted. Kaiser used a gas velocity hich he claimed gave a catalyst contact of 0.0006 ec. A square foot of the Kaiser four-layer catalyst probably weighed approximately 6.6 oz., and he has stated a maximum output of about 3750 lb. of HNO_3 per sq.ft. of catalyst per day. The actual plant yields are said to be more nearly 1056 lb. of HNO_3 per sq.ft. per day. On this last basis a capacity of 43 lb. NH_3 per oz. of Pt per day is the result. In view of the recent studies it seems probable that Kaiser could have obtained nearly the 3750 lb. of HNO_3 per sq.ft. of catalyst per day, but the secret was not due to autoxidation.

Frank & Caro Catalyst

The Frank & Caro type of catalyst consisted of a single platinum gauze made up of 0.0026-in. diam. wire and 80 meshes per linear inch. The gauze was welded to silver terminals and heated by electrical energy to about 650 to 700 deg. C. The type of apparatus used by the followers of this equipment usually consisted of an aluminum frame and a rectangular catalyst $15\frac{3}{4}$ x $23\frac{1}{2}$ in., with the flow of the air-ammonia mixture going up through the electrically heated gauze. Here precooling of the intake mixture contrasts to the preheating of the Ostwald type. The Bamag Co. has claimed that this platinum gauze, per converter, weighs about 2.89 oz. and that such an equipment oxidizes 176 lb. of NH_3 per day at 90 to 92 per cent efficiency. This is 60 lb. NH_3 per oz. of Pt per day, and is considerably higher capacity than that secured by the Ostwald type (28 lb.). The yields as reported are probably very near correct.

American Cyanamid Catalyst

The patents of the American Cyanamid Co., as taken out by Dr. Landis, cover essentially the same equipment as those of the Frank & Caro type, except that a chemically pure platinum gauze is employed, and the size is perhaps a few square inches smaller; also, the flow of the ammonia-air gas mixture is downward rather than upward as in the Frank & Caro type. Even the precooling is protected in the Landis patents. It is interesting to know that in the operation of the Landis converters no precooling device was adopted and a 0.003-in. diam. wire at 80 mesh gauze was used. A capacity of about 50 lb. of NH_3 per oz. of Pt per day could be obtained with 90 to 92 per cent oxidation efficiency.

Partington Catalyst

A composite of the Frank & Caro with the multilayer gauze has been used in England and described by Partington.[1] Here an aluminum frame holds two layers of a platinum gauze and the gas flow is up through the first layer, which is electrically heated, and then through a second gauze, which is electrically insulated from the first by small silica rods. In this apparatus it is necessary to use less than 50 per

*A paper read at the Philadelphia meeting, September, 1919, nd published by permission of the American Chemical Society.

[1] *J. Soc. Chem. Ind.*, vol. 37, p. 337r; 1918.

cent of the electrical energy consumed by the Frank & Caro type of apparatus. Precooling was avoided by Partington, and although preheating was not employed, it was recommended as desirable, provided the pre-decomposition of the ammonia could be economically prevented. The commercial units employed were small and utilized two layers of a 4 x 6 in. platinum gauze of 0.0025-in. diam. wire and 80 meshes to the inch. Both layers were of the same type of gauze. The gauze weighed 1.6 oz. per sq.ft. An output of 1026 lb. of HNO_3 per 24 hr. is claimed by Partington, and with 95 per cent conversion, and with a gauze temperature of 650 to 700 deg. C. This is equivalent to a capacity of 291 lb. of NH_3 per day per oz. of platinum. This method had been duplicated in the United States and it was never possible under any conditions to obtain these capacities with the published high oxidation efficiencies. The method of determining oxidation efficiencies for a given catalyst unquestionably governs the expression of the gauze rating. Partington recommends in another place a unit with a sectional area of 1 sq.ft. and the two layers of gauze with the electrical heat only upon the gauze which the gas stream meets first. He states that such a catalyst should produce 1 to 1.7 tons of HNO_3 per 24 hr., but the oxidation efficiency may be about 90 per cent.

Bureau of Mines Catalyst

Parsons & Jones have made patent applications for the use of a type of converter developed in some cooperative experimental work by the Bureau of Mines. Here a four-layer platinum gauze is used. The layers are in close contact, and the gauze is made of 0.0026-in. diam. wire and 80 mesh. The platinum gauze alone resembles the Kaiser type. The chief feature in this type of converter lies in the fact that no electrical heat is utilized, nor is there any preheating of either the air or air-ammonia mixtures. By the use of a non-conducting (heat-insulated) converter frame and a cylindrical form of gauze, the temperature of the catalyst is maintained sufficiently high to give oxidation conversions of from 90 to 91 per cent. A capacity of 70 lb. of NH_3 per oz. of platinum per day can be obtained on pure grades of NH_3.

Recent Developments

The nitrate division of the Ordnance Department has found that a decided increase in oxidation efficiency with an added capacity can be obtained, even with impure ammonia mixtures, by the use of a heat exchanger for the air and a subsequent mixing of the heated air with the cold NH_3 just prior to the gauze entrance. A four-layer, close-contact, cylindrical form of gauze of 0.0026-in. diam. wire and 80 meshes per in. was used in the work. The maximum intake temperature which could be secured by the exchanger was utilized. A capacity of 100 lb. of NH_3 per day per oz. of platinum at 95 per cent conversion has been obtained with a 0.0026-in. diam. wire and 80-mesh gauze. This type of converter was developed after operating experience with all other types. It differs from the Kaiser type chiefly by the utilization of the waste heat of the reaction through a properly designed heat exchanger for the intake air of the ammonia-air mixture. The function of the heating of the air is not one of activation or autoxidation, but rather a case of increasing the ammonia-air gas mixture to a temperature above 600 deg. C., without any predecomposition, in order to secure a high reaction velocity when the gas mixture comes in contact with the catalyst for but a short period.

The work of the writer has led him to utilize a heat exchanger for the ingoing air and a subsequent small mixing chamber of an iron pipe with a thin walled silica lining. A three-layer gauze mantle, with the layers separated by means of a $\frac{1}{16}$-in. diam. wire coarse mesh platinum gauze, is also recommended. The catalyst gauze should be of 0.0035-in. diam. wire and 120 mesh in order to secure greatest economy of platinum. The ideal three-layer gauze should utilize a different size mesh and wire diameter in each layer.

An examination of the above brief résumé of the various types of platinum catalysts indicates that a serious state of affairs exists. Everything from preheating to precooling and from one gauze layer to several gauze layers is employed in the commercial projects. Close-contact layers and separated layers have been recommended.

The methods of measuring temperatures, the various types of gas flow meters, and the distinctly great variation in the methods of determining the oxidation efficiencies have made an accurate scientific comparison of the above diverse data a physical impossibility. The writer is making arrangements to compare all of the above types with one standardized set of temperature, gas flow and analytical methods of estimation.

Prior to this exhaustive study it has seemed advisable to discuss some possibilities involved in this oxidation reaction. The choice, design and control of a given form of platinum catalyst must certainly be dependent upon each reaction which must be carried out, and hence a careful study of the theoretical possibilities is distinctly worth while.

Theories of Reactions

The average investigator has accepted the reaction $4NH_3 + 5O_2 = 4NO + 6H_2O$ as the primary step in the oxidation reaction. This attitude has come forth from the fact that as the temperature of the catalyst is above 620 deg. C. the only nitrogen oxide capable of existence at that temperature was NO.

Accordingly, this reaction becomes most interesting when we consider Ostwald's Law of Successive Reactions. It is recognized that whenever a chemical reaction occurs with the possible formation of intermediate compounds, the one involving the smallest loss of free energy will be formed first. Whether the formation of such can be established depends on the stability of the intermediate compound in question.

Kuhlmann originally considered that the basic reaction at the platinum catalyst was essentially

$$2NH_2 + 7O = 2NO_2 + 3H_2O$$

Mendeléeff[2] illustrates a method of producing nitric acid by passing a mixture of ammonia and air over heated spongy platinum. No reactions are written. However, he suggests that ammonia and nitric acid are the extreme compounds of nitrogen with hydrogen and oxygen, and that all the other compounds of these elements may be regarded as intermediate compounds. Mendeléeff[3] considers the following as pos-

[2]Principles of Chemistry, p. 283.
[3]*Ibid.*, page 278.

ibilities when starting with ammonium hydroxide nd substituting a hydroxyl:

(1) NH_4OH and abstracting water we get NH_3.

(2) $NH_2(OH)_2$ and abstracting water we get NH_2OH, hydroxylamine.

(3) $NH_2(OH)_3$ and abstracting water we get $NH(OH)_2$, dihydroxylamine.

(4) $NH(OH)_4$ and abstracting water we get $N(OH)_3$, orthonitrous acid.

This is particularly interesting when we note the iews which F. Raschig[4] has taken on this matter. Ie considers that $NO + H_2O$ are not the initial prodcts of the ammonia oxidation reaction, at least in n insufficient supply of oxygen. The reaction is suposed to proceed in a limited supply of oxygen to

$$4NH_3 + 3O_2 = 2N_2 + 6H_2O.$$

However, Müller[5] assumed that NH_3 dissociated into ts constituent elements, since he found the gas to conist of 59 per cent N_2 and 41 per cent H_2 at the high emperatures. Raschig considers that di-imide is essenially the first product that is formed in the oxidation eaction. He points out that hydrazine can also form. Iendeléeff pointed out that the formation of hydroxylaine in the previous mentioned work indicated the xistence of di-imide and hydrazine. Raschig has conidered the reaction in a limited oxygen supply as:

$$2NH_3 + O_2 = N_2H_2 + 2H_2O \quad \text{(chiefly)}$$

nd

$$4NH_3 + O_2 = 2N_2H_4 + 2H_2O \quad \text{(in part)}$$

nd that it is the di-imide which immediately decomoses into nitrogen and hydrogen and makes it appear hat we have

$$4NH_3 + 3O_2 = 2N_2 + 6H_2O.$$

Oesterheld[6] has studied the intermediate stages in he electrolytic oxidation of ammonia, and it was not ossible to isolate hydroxylamine. It is interesting o note that the determination of the oxidation potenials confirmed the series of ammonia to hydroxylaine to hyponitrous acid to nitrous acid.

The work on ammonia oxidation involving the use f a multilayer platinum gauze catalyst certainly inlicates that the ammonia oxidation reaction is really nore intricate than it first appears.

It would appear that the matter of decreased exosed gauze surface might not be the only limitation o a close contact of the layers if we carefully conider all of the possibilities of intermediate comounds. If the initial reaction is not a case of direct ormation of nitric oxide, but of some one of the ther possible intermediate compounds between NH_3 nd HNO_3, then the oxygen requirements at the catayst surface become quite different. The basic reaction eretofore considered has been

$$4NH_3 + 5O_2 = 4NO + 6H_2O$$

nd indicates a very high reaction order. The existnce of a reaction of the 9th order is quite unlikely, or usually the apparently high order reactions have een reduced to a series of reactions which involve imple interactions. This is unquestionably true in the ase at point, but the present uncertainty comes in the hoice of these consecutive series of reactions which esult in the production of NO from NH_3.

While it is the desire to isolate the exact series of reactions occurring at the surface of the platinum catalyst, it must be realized that the task involves many experimental data. Already there is quite an accumulation of such, yet the facts are inconclusive. A continued study of the absorption spectra may clear up the uncertainties.

The combustion of carbon has created much discussion, and even today the ultimate decision is uncertain. While Dixon, Strange and Graham[7] consider the formation of CO as the initial product, yet we find Haber[8] concludes that the initial reaction is the direct formation of CO_2. Rhead and Wheeler[9] have concluded that there is a simultaneous formation of CO and CO_2. The theoretical equilibrium indicates that carbon monoxide must be the chief constituent above 800 deg. C., and yet the evidence points to at least some dioxide. The initial formation of nitrogen peroxide rather than nitric oxide in the ammonia oxidation reaction would certainly be an important factor in the catalyst spacing relations. While the analogy to the ammonia oxidation reaction may not be completely well founded, yet it serves to show that it will be easy to develop a variety of opinions relative to this.

At one period of the past investigations, the qualitative indications were exceedingly strongly in favor of an opinion that the initial step of the oxidation reaction demanded a much larger oxygen concentration than that corresponding to the formation of nitric oxide. If such ultimately proves to be the case, the spacings between the gauze layers will demand a careful adjustment of the space-time-temperature-oxygen interdependencies.

Spacing of Gauzes

If the initial step of the oxidation reaction involves excessive amounts of oxygen, then the relationship of gas space between the catalyst layers becomes one of the greatest importance. However, this feature is important even without this oxygen factor directly entering the consideration.

The use of a single layer of platinum gauze with 0.0025 to 0.003 in. diameter wire and 80 mesh as a catalyst appears to be rather popular in the various above-mentioned systems. Since the reaction is essentially a contact process, it seems absurd that the use of much smaller free spaces between the wires of the gauze have not been adopted. From the standpoint of economy of platinum a single gauze of 0.0025 in. diameter wire and from 120 to 150 mesh is more desirable.

The function of a second or third gauze layer can be attributed to the blocking of the gas spaces of the first layer. However, if the only service which a second layer of a platinum gauze catalyst performs is one of "cleaning up" the spare ammonia molecules which pass through the interstices of the first layer, then the use of more than a two-layer gauze catalyst is probably distinctly uneconomical from the standpoint of platinum consumption.

The Bureau of Mines work involved the use of a four-layer catalyst for the purposes of heat conservation. An eight-layer catalyst has been recommended. The heat conservation argument cannot be real unless the four-layer catalyst will oxidize essentially four

times the quantity of ammonia per unit time and unit inner layer exposed surface of a single-layer catalyst. Even then, the heat conservation will only be that equivalent to the small conduction and radiation losses. If a suitable heat exchanger is employed, this heat conservation argument becomes negligible and the economical use of the platinum becomes the real issue. In other words, are more than two layers of a platinum gauze catalyst justified? The answer is certainly dependent upon the function of the catalyst, and the function of the catalyst governs in part the spacing arrangement of these two layers. Of course it is impossible to make absolute contact of one layer to the other, and it is also impractical to block up an excessively large amount of the upper surface of the second layer by the protecting under surface of the first gauze layer.

Effect of Voids Between Separated Catalyst Layers

The effect of a void heated space between the possible separated layers must be considered, even if the initial oxidation reaction goes to NO. It is quite clear that the thickness of this space must essentially be dependent upon the velocity and temperature of the gas mixture. While Landis[10] has considered that the oncoming ammonia-air mixture would be decomposed by the radiated heat from a hot gauze, such a state of affairs seems impossible. The gas cannot be heated in this manner, although convection currents may play some part. We do know that if the gas becomes heated through conduction, or by contact with the first layer of the catalyst, or through a properly designed heat exchanger, after a sufficient time the reaction $4NH_3 + 3O_2 = 2N_2 + 6H_2O$ will occur. The burning of ammonia in air is an old time experiment and involves no catalyst whatsoever.

The work of Jellinek[11] upon the nitric oxide equilibrium has shown that nitric oxide can be catalytically decomposed to nitrogen and oxygen, yet this is a matter of temperature-time-catalyst. It is also true that the velocity of dissociation of nitric acid, in the absence of a catalyst, is dependent upon the temperature. The reaction $2NO \rightarrow N_2 + O_2$ in the absence of a catalyst may account for the slow decomposition of some of the combined nitrogen only when a temperature of 827 deg. C. is attained. While NO is unstable below 1227 deg. C., yet the velocity of the decomposition reaction is distinctly slow. The partial pressure of the NO is small and the time short. Hence, it will be difficult to realize that much trouble should be encountered by this reaction in the space between the two gauze layers at the gas velocities generally employed.

Interaction of Ammonia With Nitric Oxide

Another possible source of trouble might involve the interaction of ammonia with nitric oxide. The reaction $4NH_3 + 6NO = 5N_2 + 6H_2O$ has been considered by Reinders and Cats[12]. This reaction has also been studied by Baxter and Hickey[13] in reference to a possible method for the production of pure nitrogen. Reinders and Cats state that the double decomposition reaction of NH_3 and NO can take place without a catalyzer. Experiments were conducted by them with 5 per cent NH_3 mixtures in air and with a 10 : 1 ratio of NO : NH_3. The studies were only qualitative, yet it was observed that the reaction without catalyzer, or in porcelain, proceeded slowly, while with platinum the reaction was greatly increased. However, it was noted that the relative influence of platinum upon the reactions involving the oxidation of ammonia to nitric oxide and that involving the double decomposition were quite different. The influence of the platinum catalyst upon the reaction velocity of the nitric oxide formation was much greater than on the double decomposition reaction. This relative influence of the catalyst is probably a very important factor in these reactions. Recent qualitative work has indicated that, in the absence of a catalyst, this reaction depends much upon the time-temperature factors and that it can be made small compared to the nitric oxide formation reaction at the catalyst surface. However, a certain amount of care must be exercised to prevent this reaction from assuming an important position.

Influence of Space-Time-Temperature Conditions

All of the above-mentioned decomposition reactions are dependent upon the gas velocity, or the space-time relationships. It would seem as if the spacing between the layers should then depend quite entirely upon the space-time-temperature conditions. It is surely advisable to determine these relationships for any specific commercial type of apparatus that is being utilized, and then adjust the spacings between the gauze layers in accordance with the requirements.

The writer is convinced that the close contact of gauze layers involves an unnecessary amount of protected platinum surface and is to be avoided.

The importance of the spacings between the gauze layers was clearly demonstrated in some preliminary work which was under the direction of the writer for the nitrate division of the Ordnance Department. Lieut. George Cawley originally began the study of this separated gauze layer problem because of observations made upon layers which were not in close contact with each other. It was noted that the points of the second layer, where there was contact or where small gaps existed between the gauze layers, showed the maximum amount of activation or sprouting. The activation of the lower layers in close contact to the upper has always been observed to be a very slow process. The spacing greatly facilitates this activation.

A continued study by the writer has shown that the capacities of two gauzes can be greatly increased, on a non-preheated gas mixture, by a proper spacing of the layers over that where close contact is employed. The reason for this increase is due, in part, to the greater available platinum surface exposed to the gas, but the more important feature is involved in the temperature-reaction velocity relationships within the gas system. When passing a cold ammonia-air mixture to a platinum gauze, a portion of the gas does not come in contact with the platinum surface of the first layer, but passes through the spaces of the mesh. The amount of ammonia passing these gaps depends upon the gas velocity.

Table I gives a fair approximation of the quantity of ammonia passing through the spaces of a single electrically heated gauze of 0.0026-in. diameter wire at

[10] Chem. & Met. Eng., vol. 20, p. 472; 1919.

80 mesh, provided we take into consideration that the decrease in oxidation efficiency is due to excessive gas velocity and a resultant passage of ammonia past the catalyst.

TABLE I.

Lb. NH_3 Per Oz. Pt Per Min.	Per Cent Eff.	Lb. NH_3 Per Oz. Pt Per Min.	Per Cent Eff.
0.025	95	0.095	80
0.035	93	0.120	76
0.045	90	0.145	70
0.060	86	0.190	62

It is evident that an increase of fivefold above a very low normal quantity of ammonia in unit time only decreased the oxidation efficiency approximately from 95 to 76 per cent. In other words, with a fivefold increase in the work thrust upon the first layer of a 0.0026-in. diameter wire and 80-mesh gauze we find it will still do 76 per cent of the work. This means that the concentration of ammonia in the gas escaping the first layer is exceedingly small, yet the excess of oxygen must also be small. The oxidation reaction develops so much heat that the expansion of the gases, by the increased temperature, must also be considered in this diluting effect. The greatly reduced concentration of ammonia indicates also a decreased reaction velocity, and the only means of speeding up the so-called "pick-up" reaction of a second gauze layer must be by a decided increase in the temperature of the ammonia-oxygen molecules of the gas phase. Since those molecules of ammonia which pass the gauze do not presumably make contact with the hot platinum, the only method of increasing their temperature is through conduction and convection. Closely connected gauze layers will not give sufficient time for the heating of the ammonia molecules to a temperature sufficiently high for the desired increased reaction velocity in the weak gas mixture for the available catalyst contract period. The hot gases from the reaction of the oxidation of the initial 76 per cent will transfer the necessary heat to the ammonia-air mixture which has passed the gas for the first layer, provided sufficient time is obtained. The simplest answer to this is by the use of a gas space between the layers. This space must be of sufficient depth to permit the ammonia-oxygen molecules to attain a temperature sufficiently high for a high reaction velocity when they next meet a catalyst surface. The limiting depth is that where the time-temperature conditions permit the reaction to proceed to the non-catalytic

$$4NH_3 + 3O_2 = 2N_2 + 6H_2O.$$

The interaction of nitric oxide with ammonia, as studied by Baxter and Hickey,[14] upon the preparation of nitrogen from the reaction

$$6NO + 4NH_3 = 5N_2 + 6H_2O$$

showed that the reaction was complete only when the mixture was heated to a high temperature in the presence of a catalyst (such as platinum). Fortunately, the actual relative rate at which this reaction occurs under the same conditions as the nitric oxide formation reaction is most favorable to the nitric oxide production even in the presence of a catalyst.

Since the "clean up" reaction involves a dilute ammonia gas mixture, the heat of reaction upon the second catalyst surface will be much lower than that of the first layer. In an effort to equalize the temperatures on the different layers the writer has used a coarse-meshed heat-conducting gauze. This must be fabricated of metals which do not destructively decompose dilute ammonia-oxygen mixtures or nitric oxide. A quarter-inch mesh platinum gauze has served excellently in this work. Such a metallic gauze layer separator permits the surplus ammonia molecules to be heated to a higher temperature than those of the intake gas and maintains a high catalyst temperature on the succeeding layer. Thus the reaction velocity can be increased to a point where the active surface of the under gauze layer will do its proportionate share of the work even when the first layer is subjected to a quantity of gas eight times its normal. The metallic coarse-meshed separator also enables the spacings between gauze layers to be maintained quite uniform.

The economical use of a two or three layer gauze involves the utilization of a high temperature of reaction within the gas phase and hence a preheated intake mixture. It also necessitates the use of exceedingly short periods of contact within the catalyst zone, in order to prevent undue decomposition reactions at the elevated temperatures.

Summary

This discussion of the factors affecting the design of ammonia oxidation apparatus may be summarized briefly as follows:

1. There are as many different commercial ammonia oxidation platinum catalyst installations as there are possible types.

2. The use of a suitably preheated air-ammonia mixture is pointed out as most important for the production of a sufficiently high temperature for a rapid reaction velocity of the desired reaction.

3. The use of a platinum gauze of 0.0025 in. diameter wire and 120 to 150 mesh is far more logical than one of 80 mesh, since it decreases the free gas space between the wires.

4. A three-layer platinum gauze arrangement represents probably the maximum upper limit of gauzes, if the economical use of platinum is considered. A mantle form of catalyst is desirable.

5. The gauze layers should be separated a sufficient distance in order to permit the much diluted ammonia-air mixture, which passes the first layer, to become raised to a higher temperature than the original more concentrated ammonia mixture. An increased reaction velocity may thus be obtained. A coarse-meshed platinum separator has been suggested as a means of maintaining uniformity of gas space and equality of temperature in the various layers. The temperature of the last layer will always tend to be much lower than the others unless a heat-conducting separator is utilized.

6. It is quite probable that NO is not the initial product formed in the ammonia oxidation reaction. If such is the case, the use of separated gauze layers will depend upon a careful application of space-time-temperature-oxygen factors.

7. The troublesome factors involved in the theoretical decomposition reactions when using separated gauze layers can be made to vanish by a proper control of the space-time-temperature factors.

Electric-Resistance Furnace of Large Capacity for Zinc Ores
II. Operation of Furnaces and Characteristics of Process

Details of the Experimentation Work With Electric-Resistance Furnaces of Commercial Size Based on the Author's Well-Known Plan of Making Briquets With the Zinc Ore to Be Treated and Using These Briquets as Resistors for an Electric Furnace*

By CHARLES H. FULTON

Operation of Furnace C

In setting up a charge, a 0.75-in. graphite disk, the diameter of the briquet, was placed on the graphite block *a*, Fig. 1,† and thinly coated with contact material, then the first briquet placed in position, its top coated with contact material, then the next briquet was placed in position and its top coated, then the third. This last briquet had a 2-in. hole at the center 2.5 in. deep which was formed at the time of pressing the briquet by the top pressure plate, which was fitted with a slightly tapered pin. After the twelve briquet columns were placed in position, 1.75-in. graphite pins were dropped in place in the top briquet, contact material applied, and 1-in. graphite disks, with a 2-in. hole at the centers, slipped into place, and the top connectors placed into position. The top connectors, 5 in. thick, were provided with tapered holes somewhat larger than the pins, into which the projecting pins fitted. The space between the pins and the walls of the holes in the connectors was filled with finely crushed coke. By this system the briquet columns were held firmly in position and the slight shrinkage and motion in the charge provided for.

A charge was set up in from 2 to 3 hr. by two men. In the making of the briquets care was taken to have their ends parallel and perpendicular to the axis, and all approximately of the same length. The length sometimes varied slightly, in which case and when briquets broken in the handling were used, deficient height of column was made up by the use of extra graphite disks.

After the charge was set up, a fireclay luting was spread, ring form, on the base and the retort was lowered into position by the crane. The luting made a tight joint. The exit hole at the top of the retort was left open for a short time after power was applied at the electrodes, to permit the escape of pitch fumes and the first gases, after which it was closed, and the valve *X* (Fig. 4), leading to the vapor box and condenser, opened.

In Fig. 6, the passage from the base to the upper chamber of the vapor box *v*, Fig. 4, is shown in *b*. From the vapor box, the gases passed to the central condensing chamber *p* of the condenser, thence by the cross passage *k* to the outer annular condensing chamber, which was divided, by vertical walls, into four compartments in series, the carbon monoxide finally burning at an exit at the top of the last one.

The central condensing chamber drained into the vapor box, and spelter in furnace C was tapped from the vapor boxes. In the operation of this furnace, practically nothing was found in the annular condensing chamber except a very small quantity of blue powder. This chamber was provided with tap holes at the bottom. The retort ends of this furnace were satisfactory, but the condenser was too complicated. The condensation was excellent as regards the nonformation of blue powder. After six charges, the condenser was found to be practically free from blue powder and dross. At no time did the gas flame show more than the permissible amount of zinc. Some zinc was lost by leakage at the cross passage from the central to the annular chamber, which could not be kept tight. The bottom of the vapor boxes also could not be kept tight, and spelter escaped in considerable quantity into the base and ground beneath the base. It was decided that the condenser would have to be a simpler structure and that the passage from the retort to the condenser must be simple, short, and easy of access for the purposes of cleaning. The new design gave rise to furnace D.

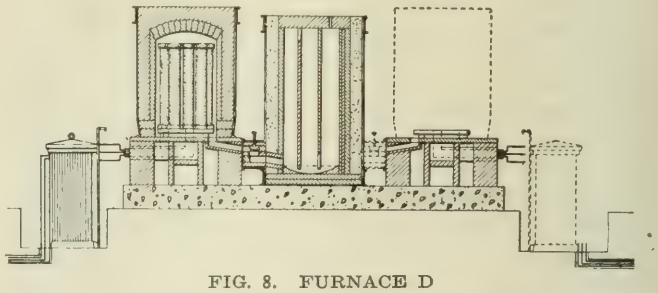

FIG. 8. FURNACE D

Furnace D

This furnace differs from furnace C in the design of the condenser. The same principle was used, but there was no heating of the retort base or the condenser. Fig. 8 illustrates the arrangement. Instead of a bottom connection from the retort base to the condenser, a top connection, shown in Fig. 9, was permanently attached to the condenser.

After the retort was placed in position, the condenser was lifted by the crane and swung into position so that the opening of the connection registered with the opening in the top of the retort. Luting was then placed around the retort opening and the condenser gently lowered to its base; this made a tight joint between the condenser and retort. When the charge was distilled, the transformer was transferred by a crane to the second retort base, the valve of the condenser connection closed, and the condenser lifted by the crane, swung around 180 deg., and set on the center of its base. The retort was then lifted about 3 in. and pulled toward the center of the building; this swept the dis-

*For Part I, describing the furnaces and process, see Chem. & Met. Eng., vol. 22, No. 2, pp. 73-79, Jan. 14, 1920.

†See Chem. & Met. Eng., Jan. 14, 1920, p. 73.

tilled briquets to the floor over an apron plate. The retort was then transferred to the other charge, the condenser set by the crane, and distillation begun on the second charge. A new charge was set up on the first base, the men being protected from the hot base by asbestos mats and shoes.

The connection was designed so that it could be readily cleaned out by the removal of the cover-plate over the graphite plug valve. The connector is by no means a perfect device and had to be cleaned every second charge, especially if the valve was not carefully closed at the end of the run. The passages also are somewhat small.

Condenser

The condenser was made of the same shell as used in furnace C, except that a steel bottom was riveted in place. It was lined first with 9-in. sil-o-cel brick followed by 4.5-in. of high-grade firebrick. Its interior diameter was 42 in. and its interior height 9 ft. It had a longitudinal partition of firebrick wall, as shown in Fig. 8, and was known as a two-pass condenser. For the initial charge, the condenser was heated by an oil burner placed into an opening at the top, the products of combustion traveling down the large pass, up the small pass, and out of the connection as a flue. Preliminary tests showed that if the condenser was heated to 940 deg. C. and then closed and allowed to stand the temperature dropped from 940 to 630 deg. C. in 16 hr. It was later found that this radiation about balanced the heat input, due to the condensation of zinc vapor, and the condenser maintained itself at a temperature of about 700 deg. C. at the inlet and 500 deg. C. at the exit. With more rapid working, it would probably have been necessary to spray the exterior with water. With less rapid working the condenser would undercool, as was the case when less than two charges were distilled in 24 hours.

Charges 7, 8, 9, 10, and 11 were distilled with this

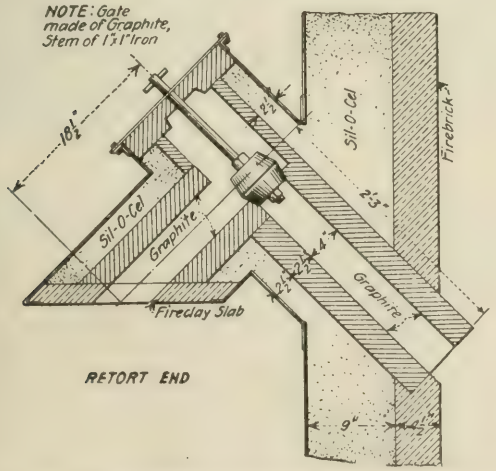

FIG. 9. TOP CONNECTION FOR ELECTRIC FURNACE

condenser, when the bridge wall collapsed at the top, at which point the temperature was about 500 deg. C. This collapse was due to carbon deposition within the firebrick localized at the iron-oxide spots of the brick. The action is due to the decomposition of carbon monoxide at the temperature existing and is elsewhere described.[1] The condenser was then repaired, the bridge wall being replaced by a 30-in. cylindrical flue tile, for a second pass. The condenser was again brought to the desired temperature by the oil burner and charges 12, 13, and 14 run, when part of the condenser brickwork, including the top tile, collapsed for the same reason as before.

TABLE II. METAL BALANCE

Runs Nos. 7, 8, 9, 10, and 11, May, 1917

Zinc in Baked Briquets	Lb.
Each charge	573.0
Zinc in five charges, total charged	2855.0
Zinc remaining in Distilled Briquets	
Run No. 1, 2.36 per cent	52.4
Run No. 2, 0.67 per cent	14.0
Run No. 3, 1.80 per cent	39.0
Run No. 4, 0.93 per cent	19.4
Run No. 5, 5.97 per cent	151.0
Total Zinc in Distilled Briquets	275.8
Zinc cast as spelter	1242.5
Zinc in scrapings from bridge wall, rechargeable @ 41.75 per cent zinc	899.0
Zinc in brick from condenser, @ 1.74 per cent zinc	115.3
Zinc unaccounted for	322.4

Summary

	Per Cent	Lb.
Spelter tapped	42.7	1242.5
Scrapings, rechargeable	30.8	899.0
Zinc in brick from condenser	3.9	115.3
Zinc in distilled briquets	9.1*a*	275.8
Unaccounted for	13.5*b*	322.4
	100.0	2855.0

a The amount of zinc left in briquets is entirely at the will of the operator; this is shown on the individual runs. The runs in this series were, in part, undertaken to obtain figures on power consumption, and certain runs were discontinued at given power inputs to determine proper point of stopping.

b This covers zinc absorption in retort hood base, and passageways, and includes zinc escaping uncondensed.

The condenser, when opened after each run, showed no blue powder, and the walls were covered with spelter in the form of droplets. There was some zinc dross in the bottom. The complete metal balance of these two runs is given in Tables II and III. In the first run 42.7 per cent of the zinc content of the charges was recovered as cast spelter bars; and in the second run 52.6 per cent. This recovery was from a practically new furnace in each instance.

The destruction of the condenser lining also took place with furnace E. It became evident, therefore, that the condenser lining would have to be made of refractory material free from iron. The only real difficulty in the condensation was the destruction of this lining at a temperature of about 500 deg. C. At higher temperatures the destruction is not noticeable, as the condenser failed only in the parts where this temperature existed. In the retort, lined with the same firebrick, no destructive action was noted; in fact, the retort lining was not repaired at any time that the plant was in operation. It is probably not possible to operate any large zinc condenser for a long period, even though every precaution is taken in construction and operation to keep it tight against air. One of the underlying ideas in a condenser of this movable type is to operate it as long as it is in good condition, then replace it with another one at the proper temperature and clean and reheat the first one.

Typical Electrical Record of Run

In Table III is given the electrical record of run 14, which is typical. It will be noted that the balance of the phases is good; in many runs it was still more even. The power factor ranges between 88 and 91. The total time was 15.5 hr. The average input was 143 kw., which is too low, but all that was available. The power consumption was 2109 kw.-hr. for the charge, which is equal to 2576 kw.-hr. per ton of ore. This is higher than necessary, as later work demonstrated.

a Recording watt-hour-meter. For kw.-hr. multiply by 33⅓.

As charge 14 was the last of a run, it was allowed to cool with the retort in place, and the briquets of every other column weighed, sampled and analyzed. The record is as follows:

Twelve columns of briquets, three each. Total height of all columns, 763 in. Weight of undistilled charge 3161 lb. Density of baked briquets, 4.15 lb. per lin.in. Density of distilled briquets, 2.82 lb. per in. Baked briquets contained 18.2 per cent zinc. Total zinc in charge, 573 lb. Total zinc in distilled charge, 0.131 per cent, or 2.6 lb. Weight of ore in charge, 1630 lb.

The density of the briquet is a measure of the distillation. The above charge lost 32 per cent of its weight; this is the proper loss for complete distillation, with the briquets used, and made of 100 parts Missouri silicate ore, 35.5 per cent zinc, 85 parts coke, and 18.5 parts pitch. A loss of 34 to 40 per cent may take place when the charge is overdistilled, in which cases only traces of zinc can be detected in the distilled briquets. In Fig. 3 are shown the resistivity curves of charges 8, 13 and 14; these are typical of briquets made of Missouri silicate ore. Toward the end of the operation the resistivity rises somewhat; and this rise, indicated at the instrument board as a drop in amperage with no voltage change made, indicates the end of the distillation period.

The distilled charge was discharged from the retort base by slightly lifting the retort and then pulling it sidewise by means of the crane. The bottom graphite electrode blocks stay in place, but the top ones are, of course, swept off with the charge. They are at once drawn from the mass of briquets and covered with crushed coke. Graphite does not oxidize readily at a low red heat, and there was very little wear on the connector blocks during the operation of the plant. The bottom blocks on the base, immediately after the discharge of the briquets, were thinly covered with crushed coke, spread by a big shovel. After an hour the base cooled to or below a dull red, when it was cleaned off by a stiff broom and new charge set up. The discharged briquets on the floor were quenched with water and then removed. With furnace F, the base was higher and the briquets were discharged directly into a steel car, quenched, and removed to the dump.

Connectors Made of Briquet Mixture

Experiments have been made with a small-scale laboratory distilling furnace, with 1¾-in. diameter briquets, in which the graphite connectors were replaced by connectors molded from briquet mixture, modified by the addition of somewhat more pitch and the use of finer coke to give additional strength. These experiments were successful and it was the intention to make full-size connectors of this type, when the work had to be discontinued. Both bottom and top connectors of this kind were to be employed, thus increasing the capacity of the retort, and doing away with the use of all graphite except the electrodes proper, which are not subject to wear. It will be noted that even with the use of graphite connector blocks, there is no regular or fixed electrode consumption in this furnace.

Use of Distilled Briquets

The distilled briquets may be used again as coke. In the briquet charges distilled in furnace F, some of the briquets were made by replacing 50 per cent of the coke by 70 per cent of distilled briquet. These caused no difficulty in the distillation, although the distilled briquets are a most unfavorable material on account of the very high percentage of residue in the ore. The distilled briquet is practically a coke containing 34.5 per cent ash, which high ash content would not be present with ordinary zinc ores in the briquet.

Furnace E

Furnace E differs from furnace D in having a bottom connection between the retort base and the condenser, this connection being part of the condenser. In order to arrange for this construction, the central part of the furnace base, which had served as a condenser support, was removed and the old passageway for zinc vapor in the retort base rebuilt. Grooves were also cut in the retort base immediately around the graphite base blocks, which drained into the vapor passage. It

was thought, in the operation of furnace D, that in the earlier stages of the operation metal sometimes condensed on the walls of the retort and drained to the base, giving rise to redistillation, which prolonged the time and increased power consumption. The results obtained with furnace E do not prove this to be true. From the construction standpoint, however, there are certain advantages in a bottom connection.

In the operation of the process, the retort from a distilled charge is usually between 1100 and 1200 deg. C., but sometimes cooler. The ideal condition for operation is one in which the retort wall temperature is always higher than the charge temperature, which can be obtained by working with good hot retorts and by rapid distillation.

Furnace E is shown in Fig. 10. It was operated in the same manner as furnace D and the results with it were about the same. The condenser was a three-pass one, the passes being made of flue tile, as shown. After nine charges, the condenser broke down in the same way as the furnace D. No metal balance was

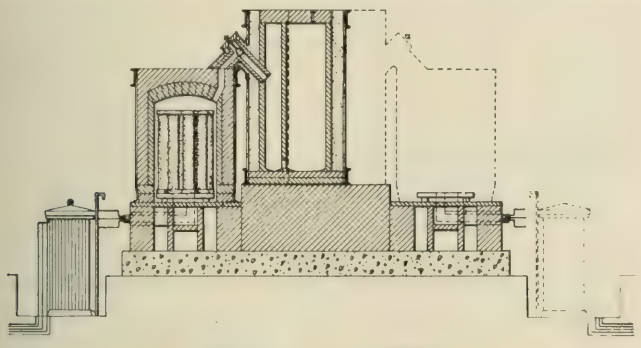

FIG. 10. FURNACE E

drawn up on this run. About 60 per cent of the zinc in the charges was recovered as cast spelter, over 1100 lb. being drawn from the condenser at one tap. When the condenser was opened, the walls were heavily coated with metal drops, dross, and dense rock oxide, and there was considerable dross in the bottom, but no blue powder. Once or twice during the campaign, the condenser valve was opened during the change from base to base and air passed through the condenser, a highly undesirable condition.

Furnace F

Furnace F was the furnace constructed for operation in connection with the new electrical equipment, consisting of three 870-k.v.a., single-phase transformers, switch connections and instrument equipment. The furnace consisted of three adjoining retort bases, two distilling retorts (identical with those used for the former furnaces), a movable combination condenser for spelter, blue powder, and oxide, and one of the old retort bases reconstructed to preheat retorts by means of oil burners. The electrical equipment was designed for extra capacity, so that it could be used in proposed subsequent work on larger units with 12-in. briquets. The foundation of the bases was built of concrete and contained a tunnel for the bus-bars from the transformers. The transformers were set as close as possible to one end of the furnace, in a shallow pit, which had waste connections to take care of the cooling water. The bases proper consisted of rectangular steel boxes filled with a firebrick arch, containing the opening for the electrodes and, on one side, a vapor passage leading to the condenser connection.

The idea was to have the extra bases form the top of the cars on which the charge of raw briquets would be set up, with the connectors in place. These cars would then be passed into the ovens and, after baking, removed, and the base with its charge picked up by crane and set on the furnace heated to a temperature of 500 to 600 deg. C. and at once distilled, thus conserving the heat energy in the hot baked charge. The movable base also served as a cover for a flue system under the base and surrounding the electrodes, which was heated by an oil burner located on the opposite side to the vapor passage. The exit flue from this system emerged from each base below the vapor passage and the products of combustion were passed to a heating chamber in the spelter condenser, to preheat this for the start of operations. This base-heating system was, in effect, the same as was used in furnace C. It was found to warp the bases and to be unnecessary, as in the case of furnace C, and was not used in subsequent operations. The electrodes were 12 in. in diameter, supported on jacks in the tunnel underneath the bases, and passed through the openings in the base, the seal between the electrodes and the openings being made by crushed carbon. The jacks afforded a ready means for slightly raising or lowering the electrode to keep it level with the top of the base. Fig. 11 shows the construction of furnace F.

The condenser proved unsatisfactory, so it was replaced with the style used on furnaces D and E. Experiments in making of zinc dust were successful, but the experiments in making oxides failed in the collecting device used. Before the spelter condenser could be again used the war conditions stopped experimental work.

The electrical system was such that the primary leads to the transformers could be connected either in delta or in Y, and the secondary leads could be brought out either in delta or in Y connection. By means of switches on the primary side, a wide range of voltage by small steps could be obtained at the electrodes. The current used was 40-cycle 13,000 volts primary, from Keokuk dam on the Mississippi River. Fig. 12 shows the wiring diagram of the three single-phase 870-k.v.a. transformers, the various connections of switches, the k.v.a. capacity of the transformers obtainable with the different connections, and the corresponding voltage at the electrodes of the furnace.

Operating With Preheated Retorts

In the furnace as at first operated, in the initial charge of any run, the retort was heated by radiation from the briquet charge, and when transferred after

FIG. 11. BASES OF FURNACE F

the distillation to the second charge was at a temperature of from 1000 to 1200 deg. C. The initial charge therefore always showed the extra power consumption necessary to heat the retort to this temperature. The ideal condition is to have the heat radiated from the retort walls to the charge rather than from the charge to the retort, which means working with hot retorts. In the case of high cost of electrical energy, the process lends itself readily to a method of working in which the retort is preheated to a temperature of 1250 to 1350 deg. C. by means of a regenerative system of preheating bases fired by gas. The use of the preheated retort reduces the time and power consumption. To the electrical power consumption in this case must, of course, be added the cost of preheating; but the electrical power consumption will be reduced by virtue of the shortened time, as this cuts down the radiation losses. In the operation of furnace F, preheated retorts were used. One of the old furnace bases was arranged for this work, the retorts being preheated by oil. In Table IV are given the results obtained.

The method adopted was as follows: A retort would be heated and then placed on the cold briquet charge, a second retort meanwhile being heated on the heating base; when this second base had attained a temperature of say 1200 deg. C., the first retort would be lifted from the charge and replaced on the heating base after the second retort was placed on the briquets; this operation was repeated until the charge was at a distilling temperature, namely 950 to 1000 deg. C.

By comparing the temperature figures, it was noted that the radiation from the retort is not rapid. The normal preheating period was 2 to 3 hr., and to obtain the total time of a charge on the base this must be added to the "Time of Distillation" given in Table IV. Under normal rapid and continuous working from base to base on the furnace, the hot retort from a finished charge would be set on a new charge, allowed to remain about 1 hr., and then replaced by a retort at 1300 to 1350 deg. C. from the heating base, and the retort just taken from the charge put on the heating base. After the second retort was on the charge about 1 hr., electrical distillation would be commenced. It need not be especially pointed out that power consumption will be lowest with such rapid and continuous working. Power consumption figures are given in Table V.

The theoretical power consumption for 60 per cent zinc ore containing 20 per cent siliceous residue, made into briquets containing 100 parts ore, 70 parts coke, and 17 parts coke pitch, is 1372 kw.-hr. exclusive of radiation losses. Of this, 421 kw.-hr., the amount required to preheat the charge to 920 deg. C., may be obtained by non-electrical means, as by preheated retorts. The carbon monoxide, which in this large-scale work may be collected, amounts to about 7200 cu.ft. per ton of ore, which at 35 cu.ft. per hp.-hr. is equivalent to 206 hp.-hr., or 154 kw.-hr. The energy in the briquet residue, in cooling from 1200 to 25 deg. C. is equal to 378 kw.-hr. Some of this may perhaps be recovered. The radiation losses can be made very

a Overdistilled; unnecessarily high. *b* Temperature measured in brickwork of base.

small, since, in the nature of the process, the heat energy developed within the charge itself is at once consumed in useful work. The retorts can be heavily insulated. In Table V the low power consumption figures with a high degree distillation were obtained under condition of rapid work, and quick transfer of retorts. Continuous steady operation will also materially aid in condensation. All of the work was carried out on exceptionally low-grade ore, giving briquets containing from 16 to 20 per cent zinc. With higher grade ores, the briquets would contain from 25 to 30 per cent zinc, but it is not probable that the power consumption would increase proportionately, since the time is not necessarily increased and hence radiation losses are kept down.

d Franklinite charge.

Zinc Dust Runs

Runs 28, 29, and 30 were made to produce zinc dust with furnace F. A condenser system consisting of two firebrick boxes, the first directly connecting with the vapor passage, and a 40-ft. train of 30-in. tile was connected with one base. To immediately cool the vapor at the exit of the vapor passage, an 8-in. iron pipe was passed through the first collecting box directly in front of the vapor passage; air was continually blown through this pipe. The zinc dust was of excellent quality throughout, free from oxide, 97 per cent passing a 200-mesh screen. The recoveries were very high, as will be noted from Table V.

Run 28 was made on franklinite ore, the briquets having the following composition: Ore, 100 parts; coke, 85 parts; and pitch, 28 parts. The briquets were in excellent condition after distillation, and it is probable that the coke and pitch proportions can be reduced. For the first large run on franklinite, it was considered undesirable to take any chance on composition.

General Characteristics of Process and Applications

The furnace and process presents the following characteristics:

1. It maintains the physical and metallurgical conditions of the present-day retort practice, in that it operates with a closed retort within the space of which is maintained a uniform temperature. This produces gas practically free from carbon dioxide, from which the zinc can be condensed as spelter without the formation of blue powder.

2. The energy for the distillation is generated within the charge itself, which fact, combined with proper heat insulation, will give the minimum power consumption possible.

3. It is a large unit furnace, the proposed 12-in. diameter, 72-in. high briquet, 19 per charge, will distill 8½ tons of roasted concentrate per 24 hr., counting on three distillations of 8 hr. each. The handling of material would all be done by crane, as in steel and copper plants. A general design has been worked out, in which the handling of material, the mixing of the briquet charge, the briquetting, the baking of briquets, the charging of retorts, and the discharge of the spent charge are done automatically and mechanically.

4. Probable costs have been calculated, which show a marked reduction over present costs. There will be no pottery and practically no consumption of fireclay. Labor costs will be low. Due to the completeness of distillation the recovery will be higher than in the present-day retort process. The cost of pitch in briquetting is not serious and with the great increase in by-product coke ovens the pitch supply will be plentiful. It has been suggested that the combination of a by-product plant and the electrical distilling furnace might work out well.

5. The process can be applied to any zinc ore, even to the so-called complex ores.

Platinum in 1919

The platinum market during the first quarter of 1919 was easier than in 1918, owing to the facts that the governmental restriction on the use of platinum had been removed and that the Government was disposing of its surplus stocks. The low price of $99 an oz. was reached late in March and was maintained about a month, but the price gradually stiffened until August, when the Government stocks were exhausted, and then abruptly rose to $110 an oz. Since the middle of August the price has continued to advance about $5 an oz. a month, the demand for the metal has been strong, and the supply has been short.

During the first nine months of 1919 about 40,400 oz. of platinum were imported, and if the importation at this rate continued during the rest of the year, and the normal domestic production of 7,000 to 10,000 oz. was maintained, about 54,800 oz. of new platinum should be available, aside from the stocks of platinum, about 65,000 oz., held at the beginning of 1919.

So far as known there has been little change in the domestic mining of platinum. The wide search made in 1918 for domestic sources of platinum has apparently yielded little results. Colombia may supply more crude platinum in 1920 than in the past, but its producing capacity is limited by the methods employed in washing the gravels from which the metal is obtained. Practically no supplies can be expected from Russia for several years. The osmiridium field of Tasmania appears to need only higher prices to stimulate larger production, but even with this stimulus it can probably produce not much more than 2,000 oz. a year.

According to James M. Hill of the United States Geological Survey, there seems to be little hope of any marked increase in the output of platinum in the United States or Canada over the small output heretofore made, and as the supplies are below normal and the demand is large it is reasonably certain that the price of platinum metals in this country during 1920 will be at least as high as it was during the last quarter of 1919, and possibly higher.

Foundry Test of Rotating Furnace

RECENT tests of operation of a 250-lb. Booth furnace* at Leitelt Bros. brass foundry, Chicago, in comparison with the performance of a gas-fired crucible installed in the same plant, furnished pertinent data on small electric furnace behavior. The electric equipment had been in operation for about two weeks when the test was initiated.

Detailed figures on the electric furnace for eleven days' run are given in Table I and on the gas-fired crucible for two heats in Table II. Table III shows comparison between the two equipments for an ordinary month's run, while in Table IV are assembled test data for four days out of the same month.

Notwithstanding somewhat adverse conditions under which this test was conducted, Table III shows a saving of over 36 per cent in melting cost in favor of the electric furnace. Furnace lining is estimated to cost in upkeep $1 per ton of metal, based on an estimated life of 400 heats. At the end of 425 heats, however, the lining was apparently as good as when first installed.

Conclusions From Test Data

Foundry records obtained while a furnace is hot are very misleading, because in a foundry such as the one being reported the average energy consumption will probably be more than 50 per cent in excess of the kilowatt-hours per ton consumed when melting regularly under the best conditions. Average operating results are therefore much better than records obtained under favorable test conditions. The electric brass furnace has proved itself to be a practicable piece of foundry equipment, irrespective of its energy consumption, but foundry men are apt to forget the over-all economies effected, and think only of the electric energy cost, if they find the kilowatt-hour consumption materially higher than was represented.

This furnace is not too small to melt red brass and gun metal with less than 290 kw.-hr. per ton (322 kw.-hr. per metric ton) and to melt yellow brass with about 240 kw.-hr. per ton (267 kw.-hr. per metric ton) when the furnace is hot and when it is being properly operated. It should be remembered, however, that furnaces are ordinarily used for one shift and allowed to cool down at night. This necessitates preheating each morning for an hour with about 50 kw. before the furnace is charged. Even this is not sufficient to heat up the furnace thoroughly, and it is not until afternoon that its point of highest efficiency is reached.

The inherent advantage of the electric furnace which overshadows all others is that it can melt metal with less loss than can the fuel-fired furnaces. As shown in Table III, a month's performance shows a shrinkage of 1.31 per cent in the one case as against 2.62 per cent in the other. Even a greater difference is noted when working on floor sweepings, turnings or light scrap.

In this particular foundry, concentrates from floor sweepings were sold for about 5c. per lb. before the electric furnace was installed, because it was not feasible to melt them in the crucibles. Now the electric furnace converts this material into ingots worth 15c. per pound.

Turnings and borings cost about 5c. per lb. less than ingots of the same analysis, and when charged into the electric furnace in large quantities, as can conveniently

*Described in CHEMICAL & METALLURGICAL ENGINEERING, vol. 21, p. 636.

Zinc poured, per cent.	12.25*	2.93	9.48*	9.94*

*Zinc added in ladle.

be done, this one item will greatly increase the saving actually shown by the electric furnace in Table III.

Melting costs are really less vital than the better and more uniform quality of castings made from electrically melted metal. Up to the present time both gas and electric furnaces have been used in this foundry, and definite data are available in a number of castings made to meet navy specifications. Seventy-five per cent of the castings which were poured from the electric furnace passed this inspection, but only 10 per cent of those poured from crucibles came within the Government requirements.

Wood Distillation Study at Virginia Polytechnic Institute

An intensive study of wood distillation has been authorized by the Virginia Polytechnic Institute. Dr. J. B. McBryde, of the department of chemistry and chemical engineering of the Institute, who will be in charge of the work, points out that wood distillation already is being conducted on a commercial scale at several points where success has attended the efforts to recover the by-products from stumps and the waste material made during the manufacture of pine lumber. He believes that a careful study of the chemical problems involved will make possible a much more effective distillation and the recovery of many valuable byproducts which can be obtained from pine.

American Patents

Complete specifications of any of the United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Concentrating Nitrous Gases.—There are several drawbacks in the processes used to concentrate nitrous gases. Thus when using alkaline solutions as absorbents, large quantities of liquid have to be evaporated. When absorbing in dry metal oxides, for instance in zinc oxide, these are usually of a so weakly basic nature that their absorbing effect is very small. A more efficient absorbent has been devised by BIRGER FJELD HALVORSEN of Christiania, Norway. A mixture of sodium hydroxide and ferric oxide or other metal oxide such as zinc oxide or aluminum oxide is used in the form of briquets. The reactions taking place when zinc oxide is used may be formulated as follows:

$$2NaOH + NO_2 + NO + ZnO = 2NaNO_2 + ZnO + H_2O$$

$$2NaOH + N_2O_4 + ZnO = NaNO_2 + NaNO_3 + ZnO + H_2O$$

The temperature of the gases not being too high, the zinc oxide remains unaltered.

Heat is then applied to cause the base and oxide to combine and we have

$$2NaNO_2 + ZnO = Zn(ONa)_2 + NO + NO_2$$

$$2NaNO_3 + ZnO = Zn(ONa)_2 + N_2O_5$$

Nitrous gases and sodium zincate are thus obtained. The gases are led off for use, and the residue, sodium zincate, is used over again at a lower temperature, acting as mixture of ZnO and Na_2O as follows:

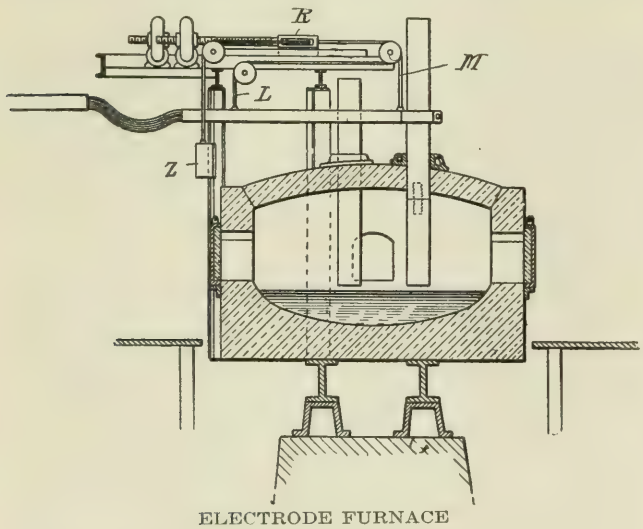
$$Zn(ONa)_2 + N_2O_4 = NaNO_2 + NaNO_3 + ZnO$$

(1,316,950; assigned to Norsk Hydro-Elektrisk Kvaelstofaktieselskab; Sept. 23, 1919.)

Process and Apparatus for Extracting Sulphur.—WILLIAM D. HUFF of LaFayette, La., has invented an apparatus for the economical recovery of sulphur from sulphur ore or other similar material containing native sulphur associated with gangue. The efficiency of the apparatus is dependent upon the melting of the sulphur in the absence of air and the conservation of a large portion of the heat imparted during the melting of the sulphur to the gangue and the parts of the apparatus which carry the sulphur-bearing material through the melting chamber. The sulphur ore is fed automatically to a series of buckets attached to rollers and formed into a continuous chain by means of links. This bucket conveyor dips beneath water contained in a tank, rises from the tank, passes through a melting chamber, and is again immersed in water in a second tank, passing over a sprocket wheel at the discharge end of the apparatus, where the gangue is dumped into cars for disposal. The two tanks containing water act as water seals for the melting chamber, thereby preventing the entrance of air to the chamber. The air is removed from the ore and the ore heated in the first tank. The heat of the gangue from which the sulphur has been removed in the melting chamber and the heat of the buckets, rollers and links are absorbed in the water in the second tank. The water is circulated through the tanks by a pump. Heat is provided to the melting chamber by means of a furnace. (1,317,625; Sept. 30, 1919; assigned one-half to James J. Connolly, of Roanoke, Va.)

Improved Sulphur Dyes From Waste Sulphite Liquor.—The fact that sulphur dyes can be prepared from concentrated waste sulphite liquor has been known for some time.[1] Such dyes may be improved, however, in the manner suggested by JACOB S. ROBESON of Pennington, N. J., by converting the calcium lignosulphonate into the corresponding salt of a heavy metal base. For example: 100 lb. of commercial 30 deg. Bé. waste sulphite liquor is mixed with 10 lb. of $FeSO_4$ dissolved in 40 lb. of H_2O. The precipitate of $CaSO_4$ is filtered off and the iron lignosulphonate precipitated from the filtrate by "salting out" with 30 lb. NaCl. After filtering and drying, the press cake is powdered, mixed with 42 lb. commercial sodium sulphide, 42 lb. sulphur and fused. When cold, the melt is pulverized. It is a black material which, dissolved in sodium sulphide solution, dyes cotton a brownish black, fast to sunlight and alkali. Sulphates of aluminum, copper, zinc, etc., may also be used, the dyes produced giving red brown, seal brown and gray brown respectively. (1,316,742; Sept. 23, 1919.)

Electrode Furnace.—WALDEMAR DYOSSEN of New York has developed an improved method of supporting the electrodes and electrode holders for furnaces of the Herould type, illustrated in the figure. The electrodes and holders are supported by cables *M* and *L* attached



ELECTRODE FURNACE

to common block *R*, which in turn is attached to threaded rod. This rod is movable by means of worm wheel and motor. An additional cable is looped through pulleys in blocks *R* and stationary pulleys located between the electrode holders. The free end of the cable is attached to counterweight *Z*. This arrangement makes possible the balancing of the weights of the electrodes and holders against each other, the weights *Z* being half the weight of one electrode and holder. This arrangement is advantageous in permitting the design of a furnace as free as practicable from heavy parts, the load on the motors being a minimum. (1,317,911; Oct. 7, 1919.)

Electrode.—SIGURD HEIER of Rjukan, Norway, increases the durability of rod electrodes in electric arc furnaces of the Schönherr type. This he accomplishes by modifying the shape of the furnace wall and also by providing a covering ring 5, Fig. 2. In Fig. 1 is illustrated the usual form of flame chamber, the flame taking a shape as shown by dotted lines 1. The rod electrode is shown at 2, the arrangement for water-cooling the electrode at 3. An insulated guide in the form of a ring is shown at 4. By modifying the shape of the furnace the arc flame takes the shape as shown

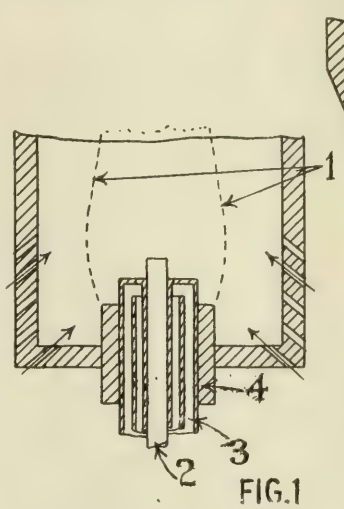


FIG. 1

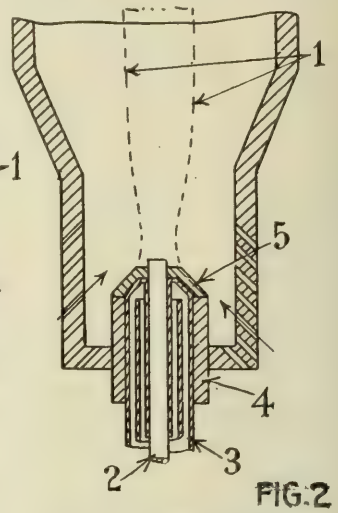

FIG. 2

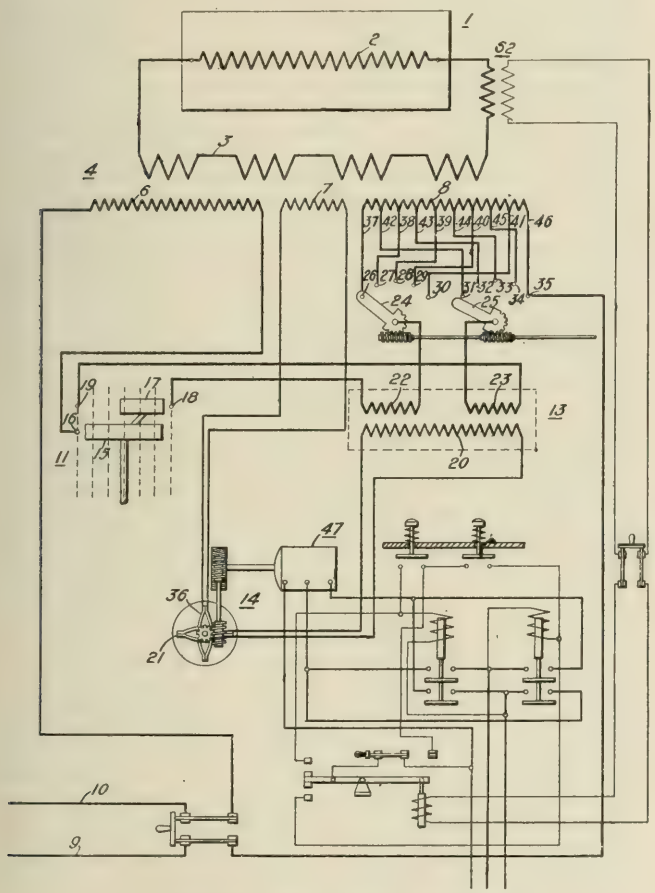
by dotted lines 1 in Fig. 2. This together with the addition of the protective ring 5 increases the life of the electrode. (1,317,576; Sept. 30, 1919; assigned to Norsk Hydro-Elecktrist, Kvaelstofaktieselskab, of Christiania, Norway.

Furnace Regulator System.—EDWIN LEHR, of Pittsburgh, Pa., has devised a method of automatically or manually regulating the power input to electric resistor furnaces without causing abrupt changes in the furnace circuit. Where electric resistor furnaces have resistors with negative temperature coefficients it is desirable to avoid overheating of the furnace and resistor by reason of any abnormal flow of current. It is also desirable to maintain a uniform temperature within the furnace and therefore to regulate the power input. To be able to perform this regulation without causing excessive variations in the load upon the generator, furnace and other electrical equipment is decidedly advantageous. This method of accomplishing the regulation without causing either breaks or abrupt changes in the furnace circuit is best understood by referring to the sketch. The furnace 1 has a resistor 2 directly connected to the secondary 3 of the main transformer 4. The main transformer has two sets of primary windings 6 and 8, the portion 8 being provided with a series of taps 37 to 46, also an auxiliary winding 7. The primary windings of the main transformer are connected to the supply conductors 9 and 10 through a transfer switch 11 and through the switch arm 24 or 25. The transfer switch consists of a band 15 in contact with 16 at all times, and a segment 17 which extends slightly more than half around the circumference of the drum on which the band and segment are mounted. The segment 17 may make contact with either 18 or 19 or with both. The taps of section 8 of the main transformer are connected to contacts 26 to 35 and to the main circuit through switch arms 24 and 25. There is an auxiliary transformer 13 which has a primary winding 20 connected in series with the stationary coil 21 of the inductor regulator 14 and a secondary winding with two coils 22 and 23. The inductor regulator has

[1] Cf. Austrian patent 2336 (1889); *Paper Making*, vol. 36, p. 351 (1917).

in addition to the stationary coil 21 a movable coil 36 connected in series with the auxiliary winding 7 of the main transformer. The inductor regulator 14 and the tranfer switch 11 are rotated in unison by motor 47 through gearing which also controls the motion of switch arms 24 and 25. During one-half revolution of the transfer switch and the inductor regulator switch arm 25 makes contact with 31, then switch arm 24 breaks contact with 26, disconnecting that portion of the main transformer between taps 37 and 42. The switch arms are so proportioned that circuit through one arm is made before the circuit through the other arm is broken. The control of the voltage impressed upon the secondary of the main transformer is effected automatically by means of a control magnet and relay switches which control the motor 47. The changes in the electrical circuit and



FURNACE REGULATOR SYSTEM

the effect of these changes caused by a half revolution of the inductor regulator and transfer switch are these: The rotation of coil 36 of the inductor regulator impresses a voltage on the primary winding 20 of the auxiliary transformer 13, and, therefore, the energy input to the furnace. Just before the coil 36 has been rotated through one-quarter turn the impressed voltage has reached its maximum, which is one-half the voltage across two adjacent taps of the portion 8 of the main transformer. Switch arm 25 is now in contact with 31 and segment 17 of the transfer switch is in contact with 19. Accordingly the two secondary windings of the auxiliary transformer are connected in opposition and across the taps 37 and 42. The flow of current through coil 23 opposes the voltage of the supply current by an amount equal to one-half that across the taps 37 and 42. The further rotation of the transfer switch breaks the contact between segment 17 and 18, disconnecting coil 22. The current now flowing through coil 23 impresses a voltage in opposition to that of the main supply current and in amount equal to one-half that across the taps 37 and 42. The rotation of the inductor regulator through another quarter turn decreases the impressed voltage to zero and switch arm 24 has been disconnected from 26. This sequence of operations has therefore gradually increased the voltage impressed on the secondary of the main transformer by decreasing the number of turns in the primary winding and this change has been made gradually and without break in the circuit. (1,320,071; assigned to the Westinghouse Electric & Manufacturing Co., Oct. 28, 1919.)

Personal

Prof. WILDER D. BANCROFT has been delivering a series of scientific lectures of a popular nature on various phases of colloid chemistry. On Jan. 17 he addressed the Indiana Section of the American Chemical Society at Indianapolis, and he will speak on Jan. 22 and Jan. 29 before the Delaware Section, at Wilmington.

Prof. C. H. DESCH has resigned from the professorship of metallurgy at the Royal Technical College, Glasgow, to become professor of metallurgy at the University of Sheffield, England, in succession to Prof. C. O. Arnold.

C. H. FARNHAM is the chemist in charge of the laboratory recently equipped by the Spencer Heater Co., at Scranton, Pa.

F. A. J. FITZGERALD, of Niagara Falls, N. Y., has returned to the United States from a trip to Ireland.

JOHN CALDER HEBDEN has just returned from Europe, where he made extensive investigations of the chemical industry in France, England and Germany.

Dr. L. O. HOWARD, chief of the Bureau of Entomology of the United States Department of Agriculture, and for the past twenty-two years permanent secretary of the American Association for the Advancement of Science, has been elected president of that institution. Dr. EDWARD L. NICHOLS was elected general secretary in his place.

Major A. NAGELVOORT, who since receiving his discharge from the Chemical Warfare Service has been with the Matheson Alkali Works, Providence, R. I., is now with Arnold Hoffmann Co., Inc., selling agent for the Matheson Works.

ABRAHAM A. ORLINGER has been awarded the Chemists' Club Hoffman scholarship for 1919-20. Mr. Orlinger received his Bachelor of Science degree at the College of the City of New York, having specialized in chemistry, and is now pursuing the chemical engineering course at the Massachusetts Institute of Technology.

Dr. R. F. RUTTAN of McGill University is scheduled to deliver an address on "The Training of the Chemical Engineer" at the annual meeting of the Engineering Institute of Canada, Jan. 27-29.

LEWIS B. SKINNER, who recently severed his connection as general manager and vice-president of the Western Chemical Co., Denver, Col., will enter the consulting chemical and metallurgical field, with offices in Denver. He has recently been retained as consulting engineer for the Midwest Oil Co.

Prof. HAAKON STYRI has resigned from the faculty of the Carnegie Institute of Technology to assume the position of chief of the research laboratory of the S. K. F. Industries at Philadelphia, Pa.

Dr. LOUIS E. WISE has resigned from E. I. du Pont de Nemours & Co., with whom he was engaged in research at

their Jackson Laboratory at Wilmington, Del., to become professor of forest chemistry at the N. Y. State College of Forestry, Syracuse University, Syracuse, N. Y.

Obituary

RICHARD COCKBURN MACLAURIN, president of Massachusetts Institute of Technology since 1909, died on Jan. 15 of pneumonia at his home in Cambridge. During Dr. MacLaurin's eleven years as president, the Institute has received large endowments and increased its educational facilities enormously. Being primarily a mathematician and an investigator of the phenomena of light, Dr. MacLaurin became a close friend of George Eastman, who has just been identified as the mysterious Mr. S-MIT-H and donor of $11,000,000 to Tech.

Dr. MacLaurin was born at Lindean, Scotland, June 5, 1870. In 1896 and 1897, he received the Bachelor of Arts and Master of Arts degrees from St. John's College, University of Cambridge. For the next ten years he was professor of mathematics and during the two last years was dean of the law school of the University of New Zealand. In 1907 he was professor of mathematical physics at Columbia University and had just been appointed head of the physics department, when he resigned to become president of Technology.

Dr. MacLaurin's work in advancing the Institute to its present dominant position will place his name foremost among the educators of the present era.

Current Market Reports

The Non-Ferrous Metal Market

New York, Jan. 19—Copper is quoted at the same figure as last week. Nickel and lead advanced 1c. and ¾c., respectively; while tin declined 1¾c.

	Cents per Lb.
Copper, electrolytic	19.50
Aluminum, 98 to 99 per cent.	31½ @ 32½
Antimony, wholesale lots	10.12½
Nickel, ordinary	43.00
Nickel, electrolytic	46.00

Iridium	oz.	250.00
Palladium	oz.	150.00
Mercury	75 lb.	93.00

The Iron and Steel Market

Pittsburgh, January 16, 1920.

The famine in steel products is unabated, as is evidenced by as high prices as formerly being paid for prompt shipment of certain products, particularly sheets, merchant bars, wire nails and plates, and in a few instances still higher prices. Also it is observed that in occasional instances, particularly in the case of sheets, mills that were obtaining large premiums for first quarter deliveries are now able to effect some future sales at the same prices.

PRODUCTION INCREASING

Production of steel continues to increase, though at no rapid rate, and may now be estimated at a trifle over 80 per cent of capacity. Labor shortage is much less a limiting factor than formerly, there being now relatively little labor shortage, in point of numbers, but there is still much to make up in point of efficiency, so many men being new to their employment, either from having shifted from one mill to another during the strike or from being entirely new to the steel industry. As the difficulty is almost wholly with common labor, it is to be expected that the teaching necessary can be completed with a month or two. The wire mills have been exceptionally short of labor, but have had a noticeable accretion of men in the past week.

The coke supply continues to be an important limiting factor in pig iron and therefore also in steel production. The shortage, as it appears in the market, is substantially as great as a few weeks ago, but the shortage has continued not because of production being curtailed, but because the consumptive demand has increased. The by-product ovens are doing distinctly better week by week, while the Connellsville region is increasing slightly, by a very few per cent in each of the past two or three weeks. The limiting factor in coke production is car supplies, at the beehive ovens of the Connellsville region and at the coal mines attempting to serve the byproduct ovens.

SALES AT VARIOUS PRICES

The occasional or chance buyer can secure steel, in the case of most of the finished products, only at prices much above the March 21 or "stabilized" price schedule, while consumers with regular mill connections frequently pay similar prices on extra tonnages, beyond what their regular sources of supply will allot them. In one sense these advanced prices represent "the market," though even from that viewpoint the market is not a quotable one, seeing that the price varies according to the buyer, the tonnage and the delivery. The great bulk of the business transacted, however, is at the March 21 prices, and in that sense the stabilized schedule is still "the market." Of sales made in December probably more than 75 per cent were made at the March 21 schedule. There are some predictions that the market will be a runaway, getting out of control of the Steel Corporation and other interests that desire to hold it to the March 21 schedule, and there are even claims made that the control has already been lost. Such statements and predictions appear to be premature. When time has been allowed for increased production to show what impress it can make upon the situation, a better basis for prediction will be afforded.

Sales in December may be analyzed with some closeness on account of the Steel Corporation's operations being known. The corporation's unfilled obligations at the end of December amounted to 8,265,366 tons, showing an increase during December of 1,137,036 tons. Shipments were about 950,000 tons, so that bookings were in the neighborhood of 2,100,000 tons. No sales were made by the corporation at above the March 21 schedule, but a portion of the business booked and reported as unfilled obligations, probably a relatively small proportion, did not have a price affixed, delivery being so extended that the price matter was left open. While the Steel Corporation by last accounts represents about 44 per cent of the steel industry (excluding the iron mills from the reckoning), the independents sold in December a much smaller tonnage. Those that have refrained from advancing above the March 21 prices were very reserved in selling, while in the case of those who were asking higher prices there was the double restriction that they were not willing to sell large tonnages and the

buyers were unwilling to contract for large tonnages. Thus it is safe to guess that three-fourths, and probably considerably more, of the steel business done in December was at not over the March 21 schedule.

Railroad Buying

While in practically all quarters the steel market situation is painted as being a very strong one, it can be observed that some of the colors used are not necessarily permanent. In particular, there is the assumption that the railroads will be large buyers after March 1, when the lines are to be returned to their owners. This view is hardly entitled to be called even a theoretical conclusion. Steel mills will not be operated upon what the public or even the railroad interests think they ought to have, but upon orders for steel the railroads are able and willing to buy and pay for. The president of the Pennsylvania Railroad has expressed himself that it is a waste of energy to consider at this juncture a program of extensive expansion of railroads during the next few years, explaining that the three things to be considered first are: Funding of the debts due from railroads to the Government for improvements made during the control period whereby the roads are handed back to the owners in better condition than when received, providing for obligations soon to mature, and providing for capital expenditures of the ordinary size.

As to large purchases of rails being about to exercise an influence upon the steel market situation, it ought to be observed that reservations have already been made, and are therefore a part of the reckoning of the steel mills, and that these reservations, with orders previously placed and stocks of rails now held by the roads, are sufficient to take care of a year's normal replacement plus any deficit that may have occurred in the past two years. The figures available are probably not consulted by those who make predictions as to rail purchases. Replacements during the three years taken as the test period to fix the rental to be paid by the Government should furnish a criterion, and averaged 1,328,316 tons a year. Replacements in 1918 were 1,111,638 tons and in 1919 about 1,350,000 tons, the two years thus showing a total deficit of 200,000 tons as compared with the experience in the test period. Stocks Jan. 1, 1920, were 375,000 tons and rails on order about 200,000 tons, while reservations already made amount to nearly if not quite a million tons.

The Chemical Market

New York, January 16, 1920.

Large manufacturers have avoided speculation and are serving their customers on the old basis wherever possible. It has become a habit of many engaged in the trade to have large stocks on hand when a shortage threatens and then dump it out at a greatly increased price. The result is an uncertainty in supply and price, as the mere rumored report of a scarcity has sent prices bouncing skyward. A fair example of this is the recent jump in *bichromate of soda*, which had a sensational rise until some hitherto unknown stocks were discovered and turned loose. Prices continued upward, then came the break and descending action back to normal. It is not often that business men of ripe experience are bitten twice by the same insect and it is the consensus of opinion that this latest rise is due to a real scarcity.

Bicarbonate of soda is again tending upward, due to a real scarcity, being quoted at 20@21c. per lb. Spot stocks on this item are scarce and it is rumored that under the present demand new price levels will be reached. *Wood alcohol* is unobtainable, the quotation remaining nominal at $4.80@$4.95 per gal. for carlots, $5.50@$7 per gal. for less than carlots. *Denatured, 188 proof*, is quoted at 76@78c. per gal., while 190 proof is quoted at 71@73c. It is rumored that the Government has withdrawn formula 1 for the manufacture of denatured alcohol, substituting a new one which will use considerably less wood alcohol and substitute pyradine, thus lowering the price on denatured and lessening the demand on wood alcohol. Manufacturers of wood alcohol are confronted with the difficulty of obtaining raw materials, and the orders placed by Japan last June and July for January delivery are now being filled, which accounts for the extreme shortage of wood alcohol

Oxalic crystals remain firm under an increased demand, and at present there is some difficulty in obtaining this item on spot. *Caustic soda* has been the center of interest, the quotation remaining $4.30@$4.50, but some sales have been reported as high as $4.65 per cwt. As all of the producers are sold up on this, it is practically impossible to obtain this item on early delivery. A strong market on *sal ammoniac* is the record for the past week, being quoted at 12¾@14c. per lb., with very little material available at this price. The coal supply is responsible for the strengthening in the ammonia grades, and this shortness will continue until there is a settlement in the coal industry. Formaldehyde has probably been the strongest feature of the market, speculation increasing and the actual supply diminishing. A larger production of alcohol is the only relief in sight from this present stringency. *Potassium carbonate* is now quoted at 26@27c. per lb., against 25c. of last week.

Coal-Tar Products. The shortage of raw materials is interfering with the manufacturers of these materials, some of the firms having withdrawn their names as producers of certain items in order to keep them for their own use in producing the finished product. The prices asked for *alpha naphthylamine* range from 35c. to 45c., while *crushed naphthaline* used as a base for beta naphthol is sold up to July by some producers. Among the short items of the coal-tar products, *benzol*, pure water white, remains nominally quoted at 27@31c. per gal. The shortage on this item is an aftereffect of the recent coal strike, but it is expected that there will be some material available around March 1.

Interest in the *waxes* has quickened during the past week, but prices still stand firm. There has been an increase of ¼c. per lb. on the two highest grades of *paraffine*, quotations now being on 133 to 135 m.c., 12c. and on 135 to 137 m.c., 13c. per lb.

In sympathy with the Savannah market, local dealers have advanced the price on *turpentine* to $1.97, with some sales recorded as high at $2.05. This jump from $1.60 of a few weeks ago has not been caused by any shortage in supply, but principally because of speculation in the London markets, where it was reported this item was short. The tremendous building campaign planned in England has caused this speculation. The London market at present is quoted around $2.10.

Vegetable Oils. The *linseed oil* market is very dull, business being at a minimum. Consumers are well covered for some time to come. The quotation of $1.77 per gal. still holds. The arrival of flaxseed from Buenos Aires continues heavy, several ships having arrived with reported cargoes of 53,000, 8,000 and 7,000 bags on board. The entrance of soap manufacturers as buyers in the vegetable oil field has had a tendency to strengthen all items on the list, noticeably *palm lagos*, which has increased to 17@18c. per lb., and peanut oil, which also jumped a cent to 24½c. per lb. It is the opinion of some that the price of 20@20¾c. per lb. for *cocoanut oil*, Ceylon grade, is not sufficient to meet the increased expenses of the crusher and this item will have a rise shortly.

Ores and Semi-Finished Products

Ferro-alloy market. General firmness in price and stronger demand in some lines marks the past week. Import and export inquiries have been heavy on ferromanganese, quoted at $140@$150 gross ton. Large demands and small stocks have occasioned this gradual rise from $130 of a few weeks past. *Spiegeleisen* continues under heavy demand because of its manganese contents of from 19 to 20 per cent, and is now quoted at $40@$50 per ton.

Among the *ores* and *semi-finished* products, *manganese* is probably the most active, inquiry being very heavy. The present quotation remains at 50@75c. per unit. *Coke* production still remains from 30 to 60 days behind schedule, and with only 30 to 35 per cent of the normal number of cars in operation, no relief is in sight. *Barytes*, white floated domestic, remains $35@$40 per ton in quotation for January contract, but it is expected there will be a rise in price for February quotations.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	.....	$0.60 – $0.65

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.50
Alpha naphthylamine	lb.	.34 —	.37
Aniline oil, drums extra	lb.	.34 —	.37
Aniline salts	lb.	.43 —	.48
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	1.75 —	.....
Benzidine, base	lb.	1.10 —	.....
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.31
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech.	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.52
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech.	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U.S.P., in drums (100 lb.)	lb.	.18 —	.....
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.75 —	.80
Cresylic acid, 95-97%, dark, in drums	gal.	.72 —	.75
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	2.25
Dimethylaniline	lb.	.90 —	1.00
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.58 —	.75
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.27 —	.30
Ortho-amidophenol	lb.	3.00 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.90 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.15 —	.18
Paranitraniline	lb.	1.00 —	1.20
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.50 —	4.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.70 —	1.00
Phenol, U.S.P., drums (dest.), (240 lb.)	lb.	.12¼ —	.19
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.45 —	.60
Salicylic acid, U.S.P.	lb.	.45 —	.50
Salol	lb.	.90 —	.95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.22 —	.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30

Toluidine	lb.	$1.70 —	$2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.45
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white, pure	lb.	.63 —	.68
Carnauba, No. 1	lb.	.80 —	.88
Carnauba, No. 2, regular	lb.	.65 —	.78
Carnauba, No. 3, North Country	lb.	.43 —	.48
Japan	lb.	.18½ —	.20
Paraffine waxes, crude match wax(white) 105-110 m.p.	lb.	.06 —	.07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.06½
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.09½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½ —	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.12
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.13
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940	gal.	$1.30
Pine oil, pure, dest. dist	gal.	....
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp.gr., 0.900-0.970	gal.	1.30
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref	gal.	.49

Naval Stores

The following prices are f.o.b., New York, for carload lots:

Rosin B-D, bbl	280 lb.	$17.00 —	$17.50
Rosin E-I	280 lb.	17.85 —	18.40
Rosin K-N	280 lb.	19.75 —	22.50
Rosin W. G.-W. W	280 lb.	22.50 —	24.25
Wood rosin, bbl	280 lb.	17.00 —	17.50
Spirits of turpentine	gal.	.... —	1.97
Wood turpentine, steam dist	gal.	.... —	1.70
Wood turpentine, dest. dist	gal.	1.64 —	....
Pine tar pitch, bbl	200 lb.	8.25 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	14.75
Retort tar, bbl (500 lb.)	bbl.	15.00 —	15.25
Rosin oil, first run	gal.	.... —	.91
Rosin oil, second run	gal.	.93 —	.94
Rosin oil, third run	gal.	1.10 —	1.12
Rosin oil, fourth run	gal.	.... —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naptha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.47½ —	$0.48½
Upriver coarse	lb.	.34 —	.35
Upriver caucho ball	lb.	.33½ —	.34½
Plantation—First latex crepe	lb.	.53½ —	.54½
Ribbed smoked sheets	lb.	.53½ —	....
Brown crepe, thin, clean	lb.	.48 —	.48½
Amber crepe No. 1	lb.	.53 —	....

Oils

VEGETABLE

The following prices are f.o.b., New York, for carload lots:

Castor oil, No. 3, in bbls	lb.	$0.18 —	$0.19
Castor oil, AA, in bbls	lb.	.21 —	.23
China wood oil, in bbls	lb.	.23¾ —	.24½
Cocoanut oil, Ceylon grade, in bbls	lb.	.20 —	.20¼
Cocoanut oil, Cochin grade, in bbls	lb.	.20½ —	.23
Corn oil, crude, in bbls	lb.	.19 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19 —	.20
Cottonseed oil, summer yellow	lb.	.22 —	.27
Cottonseed oil, winter yellow	lb.	.24½ —	.25½
Linseed oil, raw, car lots	gal.	1.77 —	1.87
Linseed oil, raw, tank cars	gal.	1.70 —	1.80
Linseed oil, boiled, car lots	gal.	1.75 —	1.80
Olive oil, commercial	gal.	2.50 —	2.60
Palm, Lagos	lb.	.17 —	.18
Palm, bright red	lb.	.16½ —	.17½
Palm, Niger	lb.	.16 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½ —	.24
Peanut oil, refined, in bbls	lb.	.27 —	.28
Rapeseed oil, refined in bbls	gal.	1.45 —	1.68
Rapeseed oil, blown, in bbls	gal.	1.60 —	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19 —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17½ —	.20

FISH

Winter pressed Menhaden	gal.	$1.20 —	....
Yellow bleached Menhaden	gal.	1.23 —	....
White bleached Menhaden	gal.	1.25 —	....
Blown Menhaden	gal.	1.26 —	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.03½ —	.04½
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	.16 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	$ .04½ —	$ .06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	13.50 —	18.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30.00 —	35.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35.00 —	45.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, TN	lb.	1.10 —	1.15
Shellac, D. C	lb.	.... —	....
Shellac, V. S. O	lb.	.... —	....
Shellac, Diamond I	lb.	.... —	....
Shellac, orange, fine	lb.	1.25 —	....
Shellac, orange, superfine	lb.	1.20 —	1.30
Shellac, A. C. garnet	lb.	1.10 —	....
Shellac, bleached, bone dry	lb.	1.35 —	....
Shellac, bleached, fresh ground	lb.	1.10 —	1.15
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	80-90 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	35-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	30-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-90 at Chester, Penn.
Silica brick	1,000	41-45 at Mt. Union, Penn.

Ferro-Alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome per lb. of Cr contained, 6-8% carbon	lb.	.20 —	.40
Ferro-chrome per lb. of Cr contained, 2-4% carbon	lb.	.21 —	.50
Ferro-manganese, 70-80% Mn	gross ton	140.00 —	150.00
Spiegeleisen, 16-20% Mn	gross ton	40.00 —	50.00
Ferro-molybdenum, per lb. of Mo	lb.	3.00 —	3.50
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	1.25 —	1.40
Ferro-uranium, 35-50%, of U	lb.	7.00 —	....
Ferro-vanadium, 30-40% per lb. of contained V	lb.	5.50 —	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	7.50
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	6.50
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	14.00
Fluorspar, gravel, f.o.b. mines	net ton	..... —	25.00
Manganese ore, 45% Mn and over	unit	.50 —	.75
Manganese ore, chemical (MnO_2)	gross ton	60.00 —	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	9.00 —	15.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	7.50 —	10.00
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

* Government prices.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.80
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	16.00
Yellow pine, 3x4 to 8x8, 20 ft. and under	M.	48.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago	M.	50.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis	M.	40.00
Roofings, tar felt (14 lb. per 100 sq. ft.)	ton	70.00
Roofings, tar pitch (in 400-lb. bbl.) carlots	ton	21.00
Roofings, asphalt pitch carlots	ton	34.00
Roofings, asphalt felt carlots	ton	63.00
Roofings, slate-surfaced, per roll of 108 sq. ft. carlots		2.25
Roofings, slate-finished shingles, 100 sq. ft. carlots		6.00
Linseed oil, raw in barrels	gal.	1.75
Linseed oil, 5 gal. cans	gal.	1.90
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.15½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13½
White lead, dry and in oil ,5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

EMERYVILLE (Oakland P. O.)—The American Rubber Mfg. Co., Park Ave. and Wait St., has awarded the contract for the construction of a 2-story factory and power house, to R. W. Littlefield, 565 16th St., Oakland. Estimated cost, $100,000.

SAN FRANCISCO—The Schmidt Lithographing Co., 2nd and Bryant Sts., retained F. Whitton, 805 Exch. Blk., to superintend the construction of a 5-story addition to its lithographing plant. Estimated cost, $228,000.

WATSONVILLE—The Ferro Products Co. is installing a modern plant on Monterey Bay and the Southern Pacific R.R., for the production of 99 per cent blank metallic oxide, that will supply a carload every 24 hours.

Indiana

FORT WAYNE—The Ft. Wayne Wks. of the General Electric Co. plans to construct a factory between Anthony Blvd. and Winter St., for the manufacture of incandescent bulbs.

Iowa

BOYDEN—The city has awarded the contract for the construction of a sewage disposal plant in connection with the proposed sewer improvement and water-works, to Ward & Weighton, 516-17 Davidson Bldg., Sioux City, at $12,200.

DES MOINES—The Pittsburgh Des Moines Steel Co. will build a 1-story, 135x300-ft. steel shop. Cranes and fabricating equipment will be installed in same. Estimated cost, $100,000. Work will be done by day labor.

Massachusetts

HOLYOKE — The American Writing Paper Co., 9 Main St., will build a 1-story, 90x92-ft. manufacturing building. Estimated cost, $25,000. Work will be done by day labor.

MONROE—The Monroe Bridge Paper Co. has awarded the contract for the construction of a 1-story manufacturing plant at Monroe Bridge, to George H. Stebbins, North Adams. Estimated cost, $25,000.

Michigan

DETROIT—The Western Gear Mfg. Co., 1040 Scotten Ave., has awarded the contract for the construction of a 1-story, 40x80-ft. heat-treating plant on Scotten Ave., to the Lundblad Co., Penobscot Bldg., Cyanide furnaces, annealing ovens, tumblers etc., will be installed in same. Estimated cost, $25,000.

Missouri

ST. LOUIS—The Century Electric Co., 19th and Pine Sts., has awarded the contract for the construction of a factory, to Stone & Webster, 120 B'way, New York City. Estimated cost, $500,000.

New Hampshire

NORTH STRATFORD — The Warner Sugar Refining Co., 79 Wall St., New York City, plans to construct a sugar refinery. Estimated cost, $1,000,000.

New Jersey

HALDEN—The town plans to improve water-works system, including a reservoir, filter plant, 16-in. main, etc.

JERSEY CITY—The Air Reduction Sales Co., Pacific Ave., plans to construct a 4-story factory building. Estimated cost, $124,000.

TRENTON—The American Steel & Wire Co., Hamilton Ave., has awarded the contract for the construction of a 1-story 60x100-ft. steel mill on Hamilton Ave., to James H. Morris, 137 East State St. Estimated cost, $25,000.

TRENTON—The Puritan Rubber Co., [illegible] Ave., plans to construct a 1-story, 25x128-ft. rubber factory. Estimated cost, $7,500. J. O. Hunt, 114 North Montgomery St., engr.

TRENTON—The Star Porcelain Co., Muirhead Ave., has awarded the contract for the construction of a 2-story, 34x68-ft. porcelain plant, to C. R. Randall, 43 North Hermitage St. Estimated cost, $6,000.

New York

CHESTER—The village plans to improve its waterworks system, including a reservoir, filter plant, etc.

ROCHESTER—The city will soon award the contract for the construction of a 3-story, 304x321-ft. junior high school at Wilson Park. Chemical equipment will be installed in same. Estimated cost, $1,200,000. Address J. M. Tracy, supt. of public school bldgs.

North Dakota

MINOT—The city will receive bids about Feb. 15 for the construction of a sewage disposal plant. F. Bass, Minneapolis, Minn., consult. engr.; E. J. Thomas, city engr.

Oklahoma

HUGO—The city voted $75,000 bonds for the construction of filtration plant.

Ohio

CLEVELAND — The Cleveland Rubber Mold & Machine Co., East 17th St. and Euclid Ave., has awarded the contract for the construction of a 1-story factory on Warner Rd., to the Moss Iron Wks., Leader-News Bldg. Estimated cost, $200,000.

CLEVELAND—The Cleveland Welding Machine Co., West 117th St. and Berea Rd., will soon award the contract for the construction of a 1-story, 42x106-ft. blacksmith shop and welding room. Estimated cost, $50,000.

CLEVELAND—The Westinghouse Electric & Mfg. Co., West 54th St., will build a 1-story, 128x165-ft. foundry addition at 1228 West 48th St. Estimated cost, $50,000. Work will be done by day labor.

Pennsylvania

ESSINGTON—The Westinghouse Electric Mfg. Co., Union Bank Bldg., Pittsburgh, has awarded the contract for the construction of a factory addition, to Westinghouse, Church, Kerr Co., Inc., 37 Wall St., New York City. Estimated cost, $2,000,000.

PHILADELPHIA—The city has awarded the contract for the extension of the Queen Lane filter system, to Edward Fay & Son, 2 South Mole St., at $367,734.

PHILADELPHIA—The Franklin Process Co., 291 Promenade St., Providence, R. I., has awarded the contract for the construction of 2-story, 75x103-ft. addition to its present manufacturing plant here, to J. W. Bishop Co., 109 Foster St., Worcester, Mass. Estimated cost, $45,000.

PHILADELPHIA—John T. Lewis & Bros., Lafayette Bldg., have awarded the contract for the construction of a 1-story, 120x150-ft. paint factory on Aramingo Ave. and Cumberland St., to the Turner Construction Co., 1713 Sansom St. Estimated cost, $100,000.

Tennessee

CHATTANOOGA—The Somerville Iron Wks., Somerville, N. J., have awarded the contract for the construction of a plant for the production of cast-iron pipe, on a site near the Signal Mountain Line, to the Austin Co., West 102nd St. and Berea Rd., Cleveland, Ohio. The plant will produce about 50,000 tons of castings annually. Estimated cost, $1,500,000.

Vermont

ST. JOHNSBURY—The Cary Maple Sugar Co. is having preliminary plans prepared for the construction of a maple sugar factory on Portland St. Estimated cost, $150,000. Webster & Libby, 534 Congress St., Portland, Me., engrs.

Wisconsin

SHEBOYGAN—The Badger State Tanning Co., South Water St. and Maryland Ave., is having plans prepared for the construction of a 4-story, 60x250-ft. tannery. Estimated cost, $50,000 to $60,000. Juil & Smith, Irving Bldg., archts. Noted Oct. 22.

British Columbia

VANCOUVER—The Canadian Carbonate Co., 1050 Hamilton St., has awarded the contract for the construction of a 1-story, 95x60-ft. factory at 11th Ave. and Yew St., to Baynes & Horie, 836 Howe St. Estimated cost, $70,000.

Quebec

MONTREAL—The Dominion Glass Co., 285 Beaver Hall Hill, has awarded the contract for the construction of a 3-story, 52x52-ft. glass factory on Wellington St., to Church Ross & Co., 10 Cathcart St. Estimated cost, $25,500.

SHERBROOKE—The Howard Pulp & Paper Co. has purchased a 9½-acre site on the bank of the St. Francis River and is having plans prepared for the construction of a wood pulp mill on same. Estimated cost, $750,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention in St. Louis, May 10 and 11.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23 to 26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10.

THE AMERICAN ELECTROCHEMICAL SOCIETY, New York Section, will hold a meeting, Jan. 23, on "Cheap Cyanide and Its Disposition."

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16 to 19.

THE AMERICAN WELDING SOCIETY will hold a meeting at Witherspoon Hall, Philadelphia, Pa., Jan. 23, at 8 o'clock, at which four papers on welding will be presented.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

Industrial Notes

THE MORSE BROS. MACHINERY & SUPPLY Co., Denver, Col., announces that it is dismantling the complete 500-ton concentrator and 250-ton copper smelter of the Penn-Wyoming Co. at Encampment, Wyo. The 16½-mile Leschen tramway is also being prepared for shipment. The tramway was built in four sections of four miles each.

THE ELECTRIC FURNACE Co., Alliance, Ohio, added a number of installations during the last quarter of 1919 which are of special interest on account of the new type of equipment involved and the special alloys which are to be melted in these furnaces. Among other installations may be noted the following for melting brass: The Standard Sanitary Mfg. Co., Louisville, Ky.; Akron Bronze & Aluminum Co., Akron, Ohio; Union Brass & Metals Co., St. Paul, Minn.; American Hardware Co., New Britain, Conn.; Roberts Brass Works, Detroit, Mich.; Kayline Co., Cleveland, Ohio. Mitsui & Co., of Japan, have purchased a 105-kw. nose-tilting furnace of one-ton capacity, together with a special motor-operated casting table, so designed that metal may be poured directly into the molds. Similar equipment, but with three casting tables, has been purchased by the Parrish Tool Co., Cleveland, Ohio.

PROF. W. F. COOVER, head of the department of chemistry of Iowa State College, delivered the principal address on Jan. 14 at the dedication of the new chemistry building of the State College of the University of Montana, at Bozeman, Mont.

THE CARBONDALE MACHINE Co., Carbondale, Pa., has recently opened a branch office in the Ellicott Square Bldg., Buffalo, N. Y., in charge of H. J. Botchford.

THE ALBERGER CHEMICAL MACHINERY Co. of 50 East 42nd St., New York City, has been formed for the marketing of special machinery for chemical plants and the purchase and sale of new and used equipment. A. H. Alberger, formerly president of the Howard Iron Works of Buffalo, is president of the new company.

A Grand Old Man

THE award of the Perkin Medal to Professor CHARLES F. CHANDLER meets with general approval. There is something about a man hale and wholesome in the ripeness of his years that appeals to the affections of men very much as a beautiful child appeals to women. It was he who put a definite meaning to 66 degree sulphuric acid, and it was he also who fixed standards for the cuts of petroleum sold for lighting and substantially put an end to lamp explosions. He has maintained an open mind and the golden merit of intelligent curiosity all his days. He has walked along the road of a long life with a good word for every neighbor that behaved himself and a cheerful boost for those whose loads were heavy.

He has stood four square and upright for chemistry when the science was in the doldrums of neglectful years, and his many thousands of students rejoice in his friendship and are thankful for his illumination and encouragement.

When he enters a room there is a surge of warmth that makes all hearts beat faster because of the contagious quality of his charity, his enlightenment, and his ever young good fellowship. All honor and praise to him!

Fraudulent Branding Of Imported Articles

OUR attention has been directed to the fact that surgical instruments are being imported into the United States, after which the "country of origin" is polished off or otherwise removed. The substitution of a domestic dealer's name or trade mark then gives the instrument the appearance of domestic manufacture, and the purchaser is consequently defrauded.

The Federal law relating to the removal of the "country of origin" from imported articles, U. S. Tariff Act of 1913, Sec. 4, Par. F, Sub-Sec. 2, reads as follows:

> If any person shall fraudulently violate any of the provisions of this act relating to the marking, stamping, branding, or labeling of any imported articles or packages; or shall fraudulently deface, destroy, remove, alter, or obliterate any such marks, stamps, brands, or labels with intent to conceal the information given by or contained in such marks, stamps, brands, or labels, he shall upon conviction be fined in any sum not exceeding $5,000, or be imprisoned for any time not exceeding one year, or both.

We bring this to the attention of American chemists and metallurgists so that they may be on their guard against similar fraudulent practice in connection with laboratory apparatus or small-scale equipment. No cases of this kind have come to our attention, but the trick may crop out at any time, and we believe a warning is warranted.

Summary Dismissal Of College Professors

THEY have been having another grand row at the University of Saskatchewan and the board of governors has dismissed summarily the heads of four departments, including those of physics and chemistry. There was, it is said, neither a hearing nor a discussion of the subject with the persons involved; they were just fired in the good old way.

We happen to be acquainted with the late head of the department of chemistry, and while we have not heard his story or that of the governors who dismissed him, we are of the opinion that he will not need to look very hard to find employment. But there are far too many of these university rows. The trouble usually has its origin in politics, because a complaisant Governor appoints some old political hacks who are not good for anything else, to serve on the board of overseers. Sometimes the only thing to do is to dismiss certain professors as speedily as possible. Sometimes a public hearing washes so much dirty linen that it is a mistake, a psychological error. Again, it may make a big row out of a little one over a single man in the wrong place. Sometimes a wild man like SCOTT NEARING, late of the University of Pennsylvania, will cause trouble, no matter what happens. But professors are hard to get, and good ones are exceedingly scarce. Teaching is the most subtle of all the arts, and only the gifted ones can really acquire it. The practice involves considerable strain to get the attention of students, and if it is to be kept the student must be made to understand. A professor has to possess, besides scientific knowledge, some of which he has to try to impart to his students, all the wiles of the professional gambler who must arouse the cupidity of his victim, often against his will and better judgment.

The faculty of a university is not a section gang with the trustees acting as joint foremen. They cannot instruct the professors how to teach, for the reason that they don't know how. There is a reasonable dignity of bearing that is and always has been necessary in dealing with those who work with their minds. A gang boss with a lot of laborers under him who cannot be instructed beyond their dead weight may achieve results by yelling and cursing and firing anybody that doesn't push with the rest, but when he advances in rank and becomes head of the corporation he can't talk to his engineers that way.

The fact is, more particularly in regard to state institutions—and this is said with all the reservations and exceptions that the conditions may warrant—we need more culture at the top. Boards of trustees and occasionally a president need the graces of life; for the benefit of all concerned it is desirable that they be gentlemen.

The Railroads And You

A DOZEN years ago "JIM" HILL, whose railroads opened up our great Northwest and who knew railroads, said that the steam lines of this country would require an expenditure of one billion dollars a year to keep them in shape to serve and aid the national growth. They didn't get it; in those days a billion dollars a year was too large to imagine. A part of it was found, but even that part steadily decreased, and during the past three years an unprecedented event occurred in American railroading—the mileage actually decreased. Mileage not only decreased, but equipment did not properly expand, with the result that right now the railroads are working to utmost capacity and there are thousands of tons of freight standing still because there is no equipment with which to move it. Railroads have reached capacity because unified control and its accompanying economies in routing have not been able to increase tonnage perceptibly. That potential freight in huge volume is dormant is evidenced by non-completion of many highway programs due to lack of construction materials, and by statistics showing that during the coal strike the railroads moved nearly twice their usual amount of freight other than coal.

Car shortage, freight and passenger congestion have become endemic, solely by virtue of lack of funds for new construction, until now, as a recent estimate by the well-informed *Railway Age* puts it, six billion dollars and three years time is the minimum by which we can expect relief! How this money and credit is to be provided is a difficult question to answer, and that aspect we do not wish to discuss at this time, but merely aim to draw attention of our readers to undoubted facts with an urgent suggestion that they give their best thought to all available angles of the situation.

The outstanding truth is this: the railroads need, *immediately*, billions of dollars for essential expansion.

But is this an important thing for me? the reader may ask. From the most selfish standpoint one might rejoin, "What engineer is there but will be favorably affected by a construction program involving two billions a year? What person, from capitalist to laborer, but will reap good times from that amount of money put into circulation?" Even the most narrow-minded manufacturer or producer could get behind a program providing new railway facilities, for it would enable him to get his supplies more freely and to ship a larger volume of products with promptitude, an asset difficult to estimate in money value.

A curious thing comes to mind in connection with the poverty of our carriers. They are poor not because there is no money or credit available, for millions are daily going into the flotation of new industrials or the development of older businesses. In order that this investment may earn its expected return, the institutions must be able to do business; but how can they function normally when the railroads could not handle the traffic offered them last year? Without being an alarmist, one could seriously doubt whether we are not at the portal of a financial panic from industrial overexpansion similar to that of the '70s caused by optimistic railroad building. Then, we built railroads into country which had no traffic to carry. Now, we are producing traffic with no railroads to move it.

But finally, each engineer, each American citizen, should consciously work for speedy expansion in sound railway facilities simply because it will redound to the everlasting benefit of the whole people. Unquestionably unrestricted exchange of intelligence and of goods is essential for our national existence. How the thing can be done is a matter where opinions can well differ; the first thing to sink into consciousness as a certainty, however, is that, to avoid national disaster, railroad facilities must keep ahead of the procession.

When we know it must be done, then we know it can be done!

Dewatering Coal in the Byproduct Coke Industry

LONG ago a low-ash coke from a high-ash coal proved to be an easy engineering proposition, for the solution of the problem had been started centuries ago in the hands of the early gold panner and perfected in the modern ore-concentration tables. It was only necessary for the coal concentrator to reverse the usual mineral process by taking his cleaned coal from the tailing discharge of either a Deister or Wilfley concentrator and draw off his mineral-ash impurities at the ore discharge. However, the solution of the ash problem did not remove all the troubles, but only substituted others of only slightly less importance. The washed coal having been in intimate contact with almost thirty times its weight of water comes out from the draining elevators and conveyors with a water content of not less than 16 per cent. Draining for twenty-four hours reduces this to 12 per cent and draining for seventy-two hours reduces it to 10 per cent. Shipment in cars over reasonably long distances often shakes the water content down to 8 per cent. The result is that from 8 to 16 per cent of water is carried into the coke retorts in the various plants throughout the country.

Hot coal possesses an oily water-repellent surface which causes all the free water contained in a coke-oven charge to segregate and flow to the floor of the oven. It is not an uncommon sight to see water flow out at the base of beehive or even byproduct ovens. At any rate, all the water of a coke-oven charge will usually be found in the lower layers which will carry a content as high as 50 per cent of water. The quenching action of this heat conductor swiftly and certainly gnaws its way deep into the refractory silica lining. In one plant the rate of spalling of the brick at the base zone is reported to be an inch and one-half per year. One-fourth this much is said to be exceptionally good practice.

This destructive action of water on the retort walls is an enormous cost, but the simultaneous loss in gas, oil, tar and ammonia is even greater. All the gas must be used in furnishing fuel when coking such wet coal, due to longer coking hours and higher heats being used. One-third of the tar and oil yields is also destroyed where coals containing a high water content are coked, and 25 per cent loss of ammonia helps to swell the losses. It is a safe conclusion that "watered stock" is death to profits in the coke industry as well as elsewhere.

A centrifugal drier capable of handling seventy-five tons per hour with thirty-five horsepower has been put into operation recently, in which well-drained coal direct from the washers has been dewatered to 6 to 8 per cent. Installation of such equipment will be but a slight addition to the average byproduct coke plant. If arrangements could be made to heat the coal, a better separa-

tion would undoubtedly be had in the centrifugal and the water not separated mechanically could be largely volatilized subsequently. What the result of charging dry, warm coal into the coke retorts will lead to is highly problematical, but it will certainly be very profitable. That it will prolong the life of the retorts and give larger yields of byproducts is certain. The big question to be answered is whether it will lead to preheating the coal previous to charging into the coke retorts and make 12-hr. coke possible.

Dr. Percy and the Intellectual Misers

DURING the first half of last century there flourished in England the Grand Old Man of Metallurgy, one of those men before the days of infinite specialization whose erudition embraced not only all branches of his own art, but stretched over philosophy and humanity as well. Fortunately, he had time for the very important task of collating and publishing practically all the available information on metallurgy, a task which he has done so well that research is seldom required to seek out original sources antedating Dr. PERCY'S books. And the fact that he spoke with discrimination may be gathered when it is remarked that, among many other things in non-ferrous metallurgy, he suggested the possibilities of hyposulphite leaching —later utilized in the Patera process for silver extraction—he realized thoroughly the limitations of bag-filtration of fume, and was able to diagnose accurately the effect of oxide in tough pitch copper.

Once, Dr. PERCY, in discussing with Mr. GILCHRIST the causes of some failures in high-sulphur irons, said: "Remember, too, that it is of very little importance to the world who discovers a fact—that is, a truth; but it is of great importance that it should be published as soon as possible, so that the discoverer may repay in some very small measure the almost overwhelming debt that he owes to the labors of others."

His life was a constant exemplification of this thought —in short, Dr. PERCY to his contemporaries and juniors was a teacher and guide whose influence will never vanish. Give us more men like Dr. PERCY and fewer miserly investigators of narrow vision who imagine that because it cost them something to discover a fact they can erect a fence about that atom of Nature with a sign, "No Trespass."

The Steel Needs Of the Railroads

IT IS a common experience of the individual, when considering his own affairs, to find that it is much easier to estimate his requirements, or draw up a schedule of what he wants, than it is to obtain means for meeting the desires. The same conditions as to wants or requirements and ability to meet them obtains also in the case of more public affairs of various descriptions, and then there are controversies. In the case of railroads, for instance, a great many people have been talking about the "needs" of the railroads without giving much thought to the ability of the railroads to pay.

If some of the suggested programs for the railroads were carried out, a very large quantity of steel would be required, and the common viewpoint is that this would mean a great deal for the steel industry. There seems to be little disposition to look at the matter from the other viewpoint—that it would also mean a very great deal of money to the railroads.

One method of approach to this subject of the steel needs of the railroads has been to take the pace at which railroad development proceeded during one period or another in the past, and then compute the amount by which the railroads have fallen short of continuing the expansion, this amount being taken as a deficiency which must be made up.

In arguments of this sort there is very frequently a fallacy, that of not considering the individual activity in question as part of the general industrial activity of the country. Generally speaking, no individual activity can increase indefinitely at a rate out of proportion to the increase in the total activity of the country. This is a perfectly obvious fact, but usually it is noted as to a given activity only when a short-range comparison brings it out. For instance, in the five years, 1895 to 1900, the production of portland cement was multiplied by 8½, while in one year, from 1900 to 1901, the production increased by 50 per cent in addition. Quite obviously that pace of growth could not continue indefinitely, for in a few decades everybody would have to be at work making or consuming cement, and when that point was reached those who were consuming cement would have to begin leaving their jobs to go to work at cement factories in order to maintain the rate of increase in production.

Now in the case of the railroads there are statistics to show that freight movement in ton-miles per inhabitant increased by 50 per cent from 1888 to 1898, ten years, then from the 1898 standard increased 50 per cent in seven years to 1905, and then from the 1905 basis increased 50 per cent to 1916, eleven years. The successive periods in which the freight movement per capita increased by one-half were ten years, seven years and eleven years. Hence, from a narrow viewpoint it might be argued that a corresponding geometric rate of increase should be provided for the future. As a matter of fact, however, these statistics show that there is something wrong. The per capita freight movement was 1,013 ton-miles in the fiscal year 1888 and 3,840 ton-miles in the calendar year 1917. At it dropped to 3,820 ton-miles in 1918, the size of the movement cannot be attributed simply to the war. This proves rather plainly that in future the individual will have to curb his desires for ton-miles. He may get a few more ton-miles each year, but not the same percentage increase year after year. The individual, however, will take care of that. He has other things to do besides consuming ton-miles.

Speaking more generally, we cannot year after year put more and more of our work into one particular activity. When an activity has caught up with the general procession it must simply take its place there. There is one thing we can do, however. Instead of building a lot more freight cars to move nineteen miles a day, we can devise means for making the existing cars carry freight further than nineteen miles a day. We can replace small steam locomotives with large electric locomotives, and instead of double tracking a single track road we can signal the single track and make it yield more service.

All this will require careful planning, and it is along such lines quite largely that the railroads are going to develop, not along the line of rushing to buy indiscriminately rails, cars, locomotives and bridges just like those that have been bought in the past.

Readers' Views and Comments

Melting Non-Ferrous Metals and Their Alloys in the Electric Furnace

To the Editor of Chemical & Metallurgical Engineering

SIR—The article entitled "Melting of Some Non-Ferrous Metals and Their Alloys in Electric Furnace," which appeared on page 673 of your Nov. 26-Dec. 3 issue, is one of great interest to the brass industry in general, and particularly to those firms and individuals that are making an intensive study of the economics involved in electric brass-melting. It would be well if every technical or semi-technical writer who discusses this subject would employ the same comprehensive and meticulous attention to detail which characterizes Mr. Collins' article.

Nor should the author be expected to give equal space and attention to each of the several electric furnace types now in commercial use for the melting of brass. He is describing a comparatively new type of furnace, hardly out of the experimental stage as yet, and, in a commercial sense, almost unknown to the brass-melting industry. Naturally he describes in considerable detail the design and performance of the furnace in which he is particularly interested, and discusses others only in a comparative way, particularly with reference to those points in which he considers his own design to be superior. Under these circumstances, it should merely be required that the author confine himself to the facts, and be reasonably fair, as well as accurate, in his comparisons. An inference which leads to an inaccurate conclusion in the mind of the reader is as misleading and as dangerous as a deliberate misstatement of fact.

In the article in question one such inference has certainly been made, possibly through ignorance of the real facts. Perhaps it should not be expected that one who has concentrated intensely upon the development of a single furnace design should, at the same time, have a broad, general knowledge of the field and of the equipment which is already in commercial use for the purposes he has in mind. On page 674, after classifying electric furnaces as, (I) solid resistance type, (II) liquid resistance type, and (III) arc type, the author discusses the application of these three types to the melting of non-ferrous metals as follows:

> In the making of brass, furnaces lying in each of the three classes have been tried out. Furnaces lying in Classes I and II lend themselves readily to the generation and control of a mild, "soaking" heat such as is required for melting volatile alloys. As illustration, the common resistance furnace lies in Class I, and the induction furnace in Class II. Furnaces in Class III generate a too intense and burning heat to be used with even questionable success in melting volatile alloys without the use of much unnecessary manipulation and watchfulness requiring much skill. Control of the electric arcs in atmospheres high or low in volatile gases, freedom from surging, low power factor and high metal loss are some of the serious problems confronting the man who would melt volatile alloys in the Class III arc furnace. Their employment had best be left for steel.

Is it not reasonable to suppose from the substance of the above paragraph that the arc type of furnace has been thoroughly tried out for melting brass and has proved a failure; that it is not and cannot be used for the purpose mentioned? That would appear to be the unmistakable inference. What are the facts? There are at present in commercial use for melting brass in the United States four distinct types of electric furnace, counting the one described by Mr. Collins. Three other types, limited in their use to a single installation in each case, may be neglected. In all there are about 200 of these furnaces, with a melting capacity in the neighborhood of 400,000 tons of brass and other non-ferrous alloys per year. Fifty of these furnaces, or 25 per cent of the total, are of the arc type. The induction furnaces in use are all of small size, while the resistance furnaces, with their "mild, soaking heat," melt metal very slowly and have a correspondingly small annual production. As a consequence, out of 400,000 tons total annual capacity, approximately 250,000 tons must be credited to a single type of arc furnace, familiarly known as the "rocking electric furnace." In other words, more than 60 per cent of the annual production of electrically melted brass is from the arc-type of furnace.

Is it going too far to say that the inference of the quoted paragraph is misleading and therefore dangerous?

The specific objections to the arc-type of furnace, listed by Mr. Collins, are: Difficulty of control, power surges, low power-factor, and high metal loss. These objections are based on theory, definitely disproved by experience. So far from requiring exceptional skill, most "rocking" furnaces are operated by men of quite ordinary intelligence who have received perhaps a week's training before taking complete charge of the furnace. Power input to the furnace is very steady and there are no surges objectionable to the power supply company, which, after all, is the party most interested in this phase of furnace operation. These furnaces consistently operate at a power factor from 85 to 95 per cent, which is entirely satisfactory to the most exacting power company. As for metal loss, the values shown in the table herewith, taken from the everyday experience of five representative plants with rocking arc furnaces, are better than those claimed by Mr. Collins for his furnace and, on the whole, rather better than the best figures so far reported for any other type of electric furnace.

OPERATING PERFORMANCE DETROIT ROCKING ELECTRIC FURNACE

Plant	Metal	Melting Time	Daily Production Tons in 9 Hr.	Kw.-Hr. per Ton	Gross Metal Loss, per Cent	Net Metal Loss, per Cent
Foundry	Yellow brass	1 hr., 13 min.	5	299	....	0.9
Foundry	Red brass	1 hr., 1 min.	6	280	0.44	....
Rolling mill	Yellow brass	57 min.	6	262	....	0.9
Rolling mill	Yellow brass	51 min.	6	224	....	1.02
Rolling mill	Yellow brass	43 min.	6	206	1.0	....

It should be noted that in four cases out of five these metal loss figures are for yellow brass—containing, in the case of the three rolling mills, from 37½ to 40 per cent zinc—and that the losses actually experienced are approximately one-third lower than those claimed by Mr. Collins for his furnace. In the case of the foundry melting red brass, the *gross* loss is less than one-half of 1 per cent, more than one-third lower than the value claimed by Mr. Collins for similar alloys.

The author of the paper has accurately listed and summarized the general advantages of electric melting,

but in stating the elements of design which must be incorporated in the electric furnace in order to realize these advantages, he has apparently been influenced almost entirely by his own experience with the resistance-type of furnace. The writer of this letter wishes to take the following exceptions to the statements made.

1. While, in order to avoid excessive maintenance costs, it is necessary to employ a "mild, soaking heat" in all furnaces which heat their refractory linings and roof to a temperature considerably above the pouring temperature of the alloy, this gentle and inefficient method of heating is entirely unnecessary in the arc furnace, where the source of heat is much nearer to the metal than to the refractories.

2. Similarly, volatile alloys do require gentle heating if they are melted in a quiescent bath, no matter how shallow, but may safely be heated much more rapidly and efficiently if the metal is stirred vigorously by the rocking motion of the furnace, and lack of uniformity in heating thus eliminated.

3. Properly speaking, a resistance furnace cannot be forced, nor a high rate of melting attained while melting brass, without seriously shortening the life of the refractories and increasing the metal loss.

4. The author states: "If the source of heat is such that its temperature lies in the temperature zone safely below the destructive distillation point of the metal, then the bath can in no manner exceed it." True enough, but in melting yellow brass (65 per cent copper, 35 per cent zinc) which requires to be poured at 1075 deg. C. and boils at 1115 deg. C., a heat source which did not greatly exceed the latter figure would never succeed in bringing the metal up to the specified pouring temperature. Even with red brass, where the range between pouring temperature and boiling point is much greater, the same thing is practically true.

It has long been admitted that the electric-arc furnace inherently possesses qualities of simplicity, reliability, efficiency and melting speed which cannot possibly be equalled by the resistance furnace. For this reason, the arc furnace is used almost exclusively in melting steel. In the case of brass, the only valid objection to the arc furnace has been that rapid heating of a volatile alloy, coupled with lack of uniformity in the application of heat—a characteristic of all stationary furnaces, whether arc or resistance—resulted in an excessive metal loss. That this difficulty has been completely overcome by rocking the furnace during melting, and so stirring the metal as to keep it thoroughly mixed, can be testified to by every user of this type of furnace, as exemplified in the instances given in the table.

In the interests of perfect fairness, it should be added that Mr. Collins has not been entirely just to the fuel-fired crucible furnace. It must be admitted by every proponent of electric melting that the electric furnace is far more costly in its initial installation than an equivalent installation of combustion furnaces. This initial handicap is, of course, readily overcome by the far greater operating economy of the electric furnace, but any fair comparison between the two should include, as an operating charge, a reasonable sum for interest and depreciation on the investment. This often means an item of a dollar or more per ton of metal melted, in favor of the combustion furnace. To ignore this item, and at the same time include a charge of 10c. per ton against the crucible furnace as interest on the cost of crucibles held in stock, which the author has done in Table I, page 677, is an absurdity.

There are other points in the article, both technical and economic, to which exception might reasonably be taken, but the above discussion covers the more important ones. The principal point for emphasis is that the article states, by implication at least, that the arc furnace is entirely unsuited for melting brass and cannot properly be used for that purpose. The fact that considerably more than half of the electrically-melted brass in the United States, including both red and yellow alloys, is melted in the rocking arc furnace is perhaps a sufficient answer to the statement. It might be added, however, that no arc furnace of this type has ever been rejected by the user as unsatisfactory in its performance, which is more than can be said of any other type of electric brass furnace, with the probable exception of the induction furnace.

Dangers of Denatured Alcohol

To the Editor of Chemical & Metallurgical Engineering

Sir—Many of the daily newspapers and other publications have been filled recently with scare heads in which "wood alcohol" has been prominently featured as responsible for many deaths which have taken place among the more ignorant and debased (or at least thirsty) of our population at widely different locations.

Wood alcohol is now sold at about three times the cost of fully denatured alcohol and is not available in large quantities at drug stores, and its sale is not pushed.

On the other hand, denatured alcohol must contain by law 10 per cent of an especially poisonous wood alcohol containing, according to regulations, 10 per cent of acetone and other ketones and aldehydes which are much more poisonous than methyl alcohol. This denatured alcohol is for sale at all drug stores in convenient packages and is advertised at garages for use as an anti-freezing remedy.

Prof. Baskerville (Chem. & Met. Eng., Dec. 10-17, 1919, and elsewhere) has warned against wood alcohol and quoted the internal revenue regulations which emphasize the poisonous properties of fully denatured alcohol.

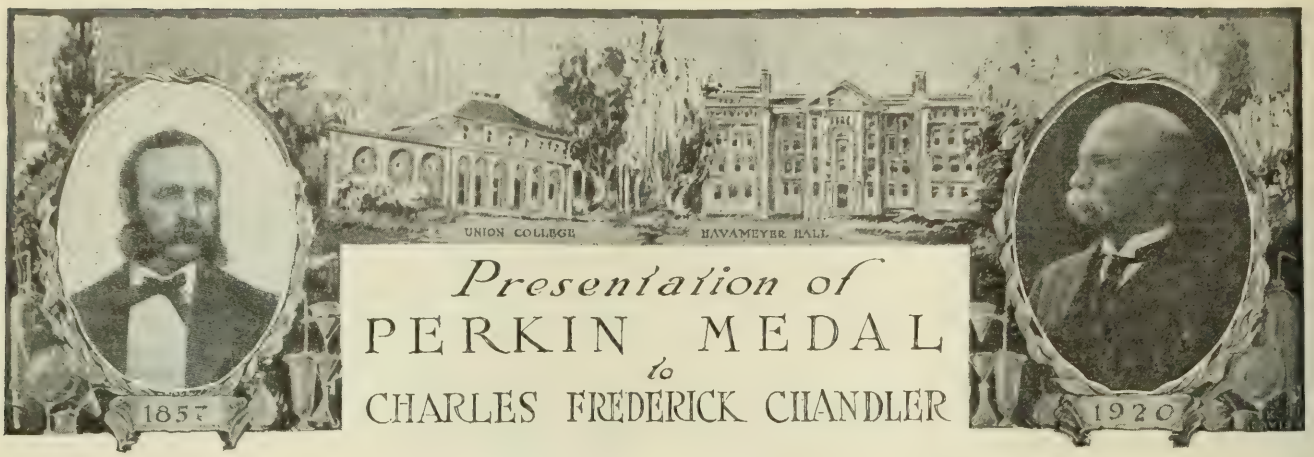
It is our professional duty to warn the public that drinks composed of *denatured alcohol* crudely doctored up will be the most likely poisonous drink to be offered surreptitiously and to caution against this danger.

H. O. Chute.
New York, N. Y.

Electrochemists Discuss Cyanide

The New York Section of the American Electrochemical Society devoted its meeting on Jan. 23 to a discussion of cheap processes for the production of cyanide. Herbert Philipp reviewed past and present methods of manufacture, pointing out the advantages and disadvantages, and also reviewed the uses of cyanide, which are mainly in the metallurgical industry for the treatment of gold and silver ores; for the fumigation of buildings, vessels, trees and food products; electroplating and case-hardening. There is apparently a market in the United States for 25,000,000 lb. per year.

W. S. Landis described a new cyanide product which has found extended use in the metallurgical industry for the treatment of gold and silver ores. Both papers will be published in full in early issues of this magazine.



Presentation of PERKIN MEDAL *to* CHARLES FREDERICK CHANDLER

AFTER introductory remarks by Charles E. Sholes, chairman of the New York section, at the fourteenth annual Perkin medal presentation meeting of the Society of Chemical Industry, Friday night, Jan. 16, and some humorous reminiscences by Dr. M. C. Whitaker, who has been intimately associated with Prof. Chandler for the past twenty years, the Perkin medal was graciously presented to Dr. Chandler by Prof. Marston T. Bogert of Columbia University. Abstracts of the addresses follow:

Personalities

By M. C. Whitaker

To attempt to tell you something new about the personal side of Dr. Chandler's career is a difficult undertaking, when speaking to people who have been his friends and associates for years. It seems on second thought, however, in view of my twenty-one years of intimate acquaintance with him, that I might be able to recall a few instances to illustrate prominent characteristics and record the impressions which these observations have left upon my mind.

Tact is one of Chandler's great achievements.

It used to be, and probably still is, a source of great amusement to the students in the upper laboratories of Columbia to drop paper bags filled with water on the heads of pedestrians. Now and then, when marksmanship is good, they hit a Fifth ave. bus.

On one occasion, the victims were two handsomely gowned, unusually dignified, middle-aged ladies of evident social position. They swung into the Havemeyer Building, almost immediately after the accident, fairly sputtering with indignation and rage, and were met at the door by the ever-ready Chandler. They were somewhat disarmed by his genial smile, glistening eye and ready wit, and accepted his invitation to his office to discuss ways and means of properly punishing wayward students. Tea was served with liberal proportions of a flavoring extract made in New England, but named after what is destined to be a famous West Indian island. Negotiations leading to the punishment of the students soon began to take a more hopeful trend, and in the course of half an hour the two ladies left the building, much improved in spirits, with their anger and rage replaced by smiling countenances and very audible laughter.

Chandler's Generosity

Chandler's earnings from his profession probably far exceed those of any other chemist in America. His generosity to others, however, keeps pace with his earnings. No one knows, not even Chandler himself, of the great financial assistance which he has given to many students. A few years ago an old Columbia graduate, unknown to most of us, died in the far West, and provided in his will that the money loaned him by Chandler from time to time should constitute the first claim upon his estate. It was with a great deal of difficulty, and without much assistance from Chandler, that we were able to determine how much money was involved. It turned out to be several thousand dollars, in loans scattered over many years.

There are doubtless many cases of this kind, because during the forty-six years that Chandler was dean of the School of Mines, he was the friend, confidant and father confessor of every one of that great army of students whose troubles are innumerable. It is out of the question for a man of Chandler's tender heart to refuse needed aid to a student. In proportion to his wealth, he gives away more than any American millionaire.

His money is not spent on automobiles, yachts, fine wines or lobster palaces, but is spent on others.

Chandler's Collection

A few months ago I was invited to attend the private exhibition of the household effects of a late citizen of New York, chiefly known for his diamonds. As I stood in the center of a special room, gazing at the wonderful collection of necklaces, bracelets, handbags, slippers, garters and stockings, I was suddenly struck with an idea. I thought of the Chandler Museum at Columbia, and recalled the innumerable times when Chandler would rush up to the University and disgorge from his pockets the most mysterious collection of teacups to illustrate some particular kind of porcelain, saucers typifying a style of decoration, vases of wedgwood, decanters showing particular design of cutting or etching, wine glasses with special features, napkin rings and even spoons. I wondered if there was anything in common between Chandler and "Diamond Jim," and then my thoughts turned to what a place must have looked like after a *joint raid* by these two collectors.

I have touched briefly upon Chandler's intuition, his ability to inspire others, his good fellowship, his tact, his good will toward others, and his hobbies. It seems to me that all of these qualities go to make up a great case for the human side of Chandler's character. I believe that we should write in large letters, and place high in the list of his distinguished achievements, and in words which I must leave to others to coin, something to express the human side of Chandler.

Presentation Address

By Marston Taylor Bogert

Dr. Chandler, Ladies and Gentlemen: The accomplishments of sixty years of tireless, skillfully-directed activity cannot be reviewed in the brief time at my disposal this evening in more than a hasty, imperfect and superficial way, and I know that my colleagues fully appreciate the magnitude of the task assigned me and the impossibility of telling Dr. Chandler in any one evening all that we would like to say in eulogy of his many notable contributions to civilization and in expression of our affection for him personally.

A day for toil,
An hour for sport,
But for a friend,
Life's all too short.

[After reviewing the ancestry, boyhood and educational training at Harvard, Göttingen and Berlin, where Dr. Chandler received the degrees of A.M. and Ph.D. in 1856 when but twenty years of age, Dr. Bogert gave an account of his teaching at Union and Columbia.]

As Educator

In January, 1857, Dr. Chandler was appointed assistant to Prof. Joy at Union College, Schenectady, N. Y., and in the spring of that year they opened the chemical laboratory there, enrolling six students in the first class. In those days, Union was one of the largest colleges in the United States, ranking even Harvard. The place was designated as an assistantship, but the budget item provided, namely, $400, was for a janitor, and, as a matter of fact, the new incumbent actually did janitorial service as well as teaching, making the fires, carrying the coal and ashes, and doing other tasks of like character. In April of the same year, Prof. Joy was called to Columbia College, and Dr. Chandler succeeded him at Union, lecturing to 150 seniors, most of them older than their teacher. The late United States Senator Warner Miller was a later pupil.

Little attention had been paid at Union to instruction in the sciences, so that permission was obtained without difficulty to introduce new courses from time to time, with the result that he was soon giving lectures in general, inorganic, organic, analytical, and agricultural chemistry, blowpipe analysis, mineralogy, and geology.

For more than seven years he remained at Union in charge of the laboratory and lecture work in chemistry and other subjects, rapidly building up a strong and influential branch of the college's work.

Columbia School of Mines

Union College possessed a wonderful collection of minerals which had been gathered together by Charles M. Wheatley of the Wheatley and Perkiomen mines of Pennsylvania, and had been purchased for the College by Mr. Delavan, owner of the Delavan House at Albany, N. Y., for $10,000.

It was the existence of this splendid collection of minerals that brought Dr. Egleston to Schenectady in 1864, and made him acquainted with Prof. Chandler. He was somewhat startled to see the latter conducting commercial assays of ores for gold and silver, and to learn that he gave lectures on the subject also, as he had been under the impression that only the graduates of foreign schools of mines were equipped to do work of that nature. This was one of the things that led Dr. Egleston to the conclusion that Chandler was the man needed to join General Vinton and himself in the project of establishing a school of mines in New York City as part of Columbia College. A formal invitation arrived not long afterward, and Dr. Chandler signified his acceptance. To the credit of his deep sense of patriotic duty be it recorded that he delayed his departure from Schenectady until after election day, 1864, in order that he might not lose his vote for Abraham Lincoln.

Few Technical Schools at That Time

There were at that time but few technical schools in the country, and no school of mines, and many people regarded this project of founding a school of mines in New York City as decidedly visionary and unpromising. Nevertheless, the three professors concerned were so enthusiastic on the subject and had such faith in its ultimate success that they agreed to undertake the work without any guaranteed salary whatever, other than the fees from such students as might register for the course.

George T. Strong, William E. Dodge, Jr., and several other good friends provided a total of about $5,000 to equip the laboratories. A fine cabinet of minerals was donated by Gouverneur Kemble, and President Barnard, Dr. Torrey and other Columbia trustees encouraged the enterprise in every way possible.

Some vacant rooms in the basement of the old college building on Madison Ave. and 49th St. were fitted up for the laboratories and accommodation there provided for twelve students. The new school opened its doors Nov. 15, 1864, and twenty-four students presented themselves for admission on that date. Chandler has often told, in his own inimitable way, how he used to open the laboratory at 7 a.m., start the fire to warm it up, sweep and clean the room, and do all in his power to make the place as attractive as possible and the lot of the students a pleasant one. It was inevitable that there was passed on to these students at the same time some of his own overflowing energy and enthusiasm.

Growth of the School

The school was a phenomenal success practically from the beginning. During the entire winter, carpenters and plumbers were kept busy installing new desks for new students, and the number of students for the first year finally rose to forty-seven. During the following vacation a large four-story factory building on the campus was placed at the disposal of the school, and sufficient funds were provided to equip it with suitable laboratories, lecture rooms, etc. Accommodations were arranged for seventy-two students. Eighty-nine registered for the second year and the school was thronged. The success of the venture being so great and so obvious, the trustees finally arranged to place it on a substantial basis as an integral part of the college work. Prof. J. S. Newberry was called to the chair of geology, relieving Chandler of this subject, and a complete faculty of professors and junior officers was established. A new building was erected especially for this new school, the plans of which were drawn up by Dr. Chandler himself. It was designed to accommodate 150 students, and was soon overflowing.

The school continued to prosper and its field to unfold and expand until what began as the School of Mines in a few basement rooms with twenty-four stu-

dents has now become a whole group of great technical schools (mines, engineering, chemistry, architecture and pure science) with many thousands of students and six splendid buildings and with a reputation which is not merely national, but international.

Thirty-three Years as Dean

Although at first appointed professor of geology, analytical and applied chemistry and assayer, Dr. Chandler soon was made dean of the school and became its leading figure, all-pervading geuius and chief driving force. For thirty-three years he served as dean, and of the many able and devoted men who have built their lives into this splendid institution, none have contributed so much as he. In 1897, when the university moved to its new site upon Morningside Heights, Prof. Chandler resigned his post as dean, but continued in charge of the department of chemistry as the "Mitchill professor of chemistry" until his retirement from active service, July 1, 1911. In the early days, he lectured upon all branches of chemistry, both theoretical and applied, but as the staff grew in numbers he transferred to his younger associates most of this, so that during the later years of his professorate his lectures were mainly upon general and industrial chemistry.

It was largely through Dr. Chandler's personal solicitation and influence that the Havemeyer family generously provided the funds for the erection of a splendid chemical building at the new site. Before drawing up the plans for this building, Dr. Chandler made a special trip to Europe for the purpose of examining the construction of the leading chemical laboratories there, with the result that Havemeyer Hall, when finally completed, embodied the best that was then known in regard to laboratory construction, and was universally regarded as the finest chemical laboratory in the United States.

Created Chemical Museum

The Chemical Museum of Columbia University is his own creation, begun and expanded through his indefatigable labors and personal generosity and, in recognition of this fact, the trustees have very appropriately named it the Chandler Chemical Museum. For many years it was unique, and is believed to be still the most complete of its kind in the world. There the visitor will get a very vivid impression of the extent to which our modern civilization is dependent upon the science of chemistry.

[Dr. Bogert here read the resignation of Prof. Chandler from the faculty in 1910 and several glowing tributes paid to him at that time. His work at the New York College of Pharmacy and the College of Physicians and Surgeons was briefly stated.]

As Author and Editor

As an author, Prof. Chandler has a long list of publications to his credit, embodying the results of research and invention, official reports, public addresses, sanitary regulations, analyses of waters, minerals, milk, etc., a survey of which shows at once the wide range of his interests and the versatility of his genius.

As an editor, he supplied for several years an American Supplement to the monthly edition of the *Chemical News* (of England); and, in July, 1870, in association with his brother, Prof. William H. Chandler, of Lehigh University, founded the *American Chemist*, and continued its publication until April, 1877, when it was given up, to make way for the *Journal of the American Chemical Society*. Another editorial task, and one which proved most laborious, was that of chemical editor for Johnson's Encyclopedia.

As Industrial Chemist

Chandler was one of America's first great industrial chemists, and aided and enriched almost every chemical industry which this country supported during the two decades following 1866.

His services have always been in demand by those great corporations whose manufacturing processes are based upon chemistry, for he has not only a thorough knowledge of that science, but also an alert mind stored with original and valuable ideas. He has been generally acknowledged to be the highest authority in this country in the field of industrial chemistry. While other able and eminent chemists have their single specialties, Chandler has been called a specialist in all branches, and is especially expert in sugar refining, petroleum refining, the manufacture of illuminating gas, photomechanical processes, and calico printing. He has served as chemist for the N. Y. Gas Co., and for the N. Y. Steam Sugar Refining Co., as consultant for the Standard Oil Co. and for various other great business interests.

He has no rival to the title of dean of the industrial chemists of the United States. Even now, at the ripe age of eighty-three, he is laboring daily in the offices of the Chemical Foundation, Inc., helping to prepare our country for the German chemical competition.

As Contributor to the Progress of Chemical Industry

One of his first and far-reaching contributions to the progress of chemical industry was the invention of the system of assay weights, as outlined in his article entitled "A New System of Assay Weights," which appeared in the American Supplement of the *Chemical News* of August, 1869. Although this system has been for years the one used by all assayers and metallurgists, it is safe to say that but few of them are aware of the fact that it was Chandler who introduced it, with the aid of Becker & Son, who manufactured the weights according to his specifications.

His observations and belief in the possibilities of the Castner process for the production of caustic soda by electrolyzing sodium chloride in a "tipping cell" with a flowing mercury cathode were communicated to the Matheson interests and they later, acting upon his advice, purchased the American patent rights and established in this country a great electrochemical industry at Niagara Falls, N. Y.

Water was one of the subjects to which he early turned his attention, and complete analyses were made of nearly all the famous Saratoga Springs waters. His first important commission was the investigation of boiler incrustations and feed waters for the New York Central R.R. Co., which investigation was begun in 1863 and completed in 1864 at the School of Mines.

It may be of interest also to note, in passing, a fact which is probably unfamiliar to many of this audience, namely, that it was due to Chandler's advice and urging that the firm of Eimer & Amend started their laboratory supply business in 1874. The founders of this firm were German apothecaries who were dissatisfied with the standard of purity of the American pharmaceutical products of that day and therefore began the

importation of alkaloids, etc. Chandler, who was personally acquainted with them through his connection with the College of Pharmacy, called at their office and urged them to extend this branch of their business and to include also the importation and manufacture of chemical apparatus. How great an assistance it has been to the cause of American chemistry to have had at hand the stores of fine chemicals and apparatus provided by this firm, it is difficult to over-estimate.

As Patent Litigation Expert

So much of his time was occupied in great patent suits that but little was left for investigation. I well recall his advice, when I asked him to give me some guiding principles in serving as chemical expert in such litigation. His answer was brief and to the point: "Know your lesson. Tell the truth. Don't be afraid to say 'I don't know.'"

The most famous suit in which he participated was that brought in the interest of the widow and assignees of the Rev. Hannibal Goodwin, an Episcopalian minister of Newark, N. J., and an amateur photographer, who was the first successful inventor of a flexible nitrocellulose film for the kodak camera and for moving picture negatives and positives. Goodwin's opponents kept him in the Patent Office ten years before he could get his patent, when he died. Thirteen years of most strenuous litigation was required to win against the infringer. Rather than have a court investigator examine the books to determine the proper award, the defendant settled with the plaintiffs by the payment of $5,000,000, which is believed to be the largest amount ever secured in a patent suit.

Other noteworthy suits were the first synthetic coal-tar color cases, of which there were five concerned with artificial alizarin, and others later which had to do with the Roussin patents, owned by Poirier & Co., of Paris, for the azo dyes obtained by diazotizing sulphanilic or naphthionic acid and coupling with suitable amines, amides or phenols; but to review even briefly the many notable suits in which he has been engaged would take an entire evening, as they include subjects in almost every branch of chemical industry.

As Builder of American Chemical Organizations

As a builder of American chemical organizations, Dr. Chandler has played a notable rôle.

He was president of the convention of chemists which gathered at the grave of Dr. Joseph Priestley, Northumberland, Pa., July 31 and Aug. 1, 1874, to celebrate the centennial of chemistry, and where the first seeds were sown of what was later to become the largest and most powerful national organization of chemists the world has ever known, and of which Chandler has been twice president and many times a director—the American Chemical Society.

The founding of this society is described in the issue of the *American Chemist* of May, 1876. After the centennial meeting in 1874, the project of establishing a chemical society was often discussed by many of the New York chemists, and it was finally decided to call a meeting for the purpose. As was to be expected, Chandler at once became the recognized leader in the movement and, under date of Jan. 22, 1876, a self-constituted committee, of which he was the guiding genius, sent out a circular letter to all chemists in New York and vicinity inviting co-operation in the formation of a local chemical society. Emboldened by the number of favorable replies received to this communication, the same committee, on March 22, 1878, distributed a second circular letter suggesting the desirability of organizing a national instead of a local chemical society, and submitting a tentative draft of a constitution and bylaws for an American Chemical Society. So many approved the proposal that a call for an organization meeting was issued on March 27, 1876, and on April 6, 1876, this meeting was held in the rooms of the New York College of Pharmacy, with thirty-five chemists in attendance and with Dr. Chandler as presiding officer, and the American Chemical Society was born.

There were, to be sure, some conservative and timid souls who feared for the success of the venture, but they were in the minority fortunately, and the progressives rallied in overwhelming numbers to Chandler's support. Among the latter was another of the great builders of American chemical industry, a former president of this society, Dr. William H. Nichols, who at that time uttered the following prophecy: "We do not come here expecting to find a society ready formed, with a library and a fine building; those will come in time. There is enough enthusiasm among the chemists to give us them by and by." Two of the men largely responsible for the fulfillment of that prophecy were Chandler and Nichols.

Chandler is thus the father of the American Chemical Society. The handful of members has grown to over 13,000, and this vast membership is drawn not only from our own land but from all quarters of the globe. The few hundred dollars income of those days has swelled to an annual budget of close to a quarter of a million. There are more local sections now than there were chemists at the organization meeting forty-four years ago. To take the place of the *American Chemist*, the society publishes three great journals, which circulate among all the civilized nations of the world.

It is also just to refer to Dr. Chandler as the father of the Chemists' Club, for, although he was not the originator of the movement which led finally to its establishment, he had always spoken in favor of such an affiliation of our New York chemists, and he was the unanimous choice for the club's first president. Without his wise and experienced guidance, his unquenchable optimism, and his financial assistance, the club would have had a hard struggle for existence. He has been its chief reliance through good and bad weather.

Other Honors Received

In addition to the honors already recorded, the University of Göttingen, upon the fiftieth anniversary of his Ph.D. degree, officially renewed this degree and sent him a parchment to that effect.

He received the M.D. from the University of New York in 1873, and the LL.D. from Union College the same year. In 1900, Oxford University conferred upon him its D.Sc. This was indeed a signal distinction, as the only previous recipient of this honorary degree from Oxford had been the Prince of Wales. Chandler was thus the first scientist upon whom it was conferred. In 1911, Columbia also awarded its LL.D.

He is a member of the National Academy of Sciences, of practically all the leading chemical societies both here and in Europe, and of many other scientific, learned, and philanthropic organizations.

On April 30, 1910, a huge banquet was given in his honor by the chemists of America and a bronze bust of life size was presented to Columbia University. It is

an excellent likeness, and now is housed in Havemeyer Hall where all may see it.

When the Society of Chemical Industry decided to recognize its large and influential American Section, and to draw closer the bonds uniting the two nations, it made inquiry as to whether there was any one American chemist who, by the common consent of his colleagues and in virtue of his achievements, might properly be regarded as first among our industrial chemists. There was no question that Chandler was, and had been for many years, the leading figure in this field, and he therefore received the unprecedented compliment of election to the presidency of this great international society, being its first American president, and thus joined the group of distinguished men who had held that high office previously.

The Medalist

Were Sir William Perkin himself alive, I am sure that nothing would have given him more pleasure than to have seen the Perkin medal presented to his dear friend Chandler, for when Sir William and his family last visited our shores, the Chandler home was their home.

Perkin's contribution to applied chemistry was the founding of a great industry, which has had a most marvellous development and by which civilization has been brilliantly advanced. Chandler's greatest contributions have been in the most important chemical industry of all—the making not merely of chemists, but of men, and in applying his chemical knowledge in the service of mankind to protect the health of the community and to save human life.

Thousands of lives and an immense amount of suffering are saved annually as the direct benefit of the sanitary reforms which he initiated. Other thousands of lives have been so profoundly impressed by his noble example and inspiring altruism that the world is a better and a happier place to live in. The bounds of such an influence are far-reaching indeed, and its duration outruns the lives of many generations.

No student ever attended his courses without being immediately struck with the fact that here was a man of lofty ideals and noble aims who was honestly and unwearyingly trying to be of service to his day and generation, and whose actuating impulse might not improbably have been expressed somewhat as follows:

> If men can say—if they but can—
> "He did his best; he played the man;
> His way was straight; his soul was clean;
> His failings not unkind, nor mean;
> He loved his fellow men and tried
> To help them"—I'll be satisfied.

I am sure that I speak not alone for myself, but also for this entire gathering and for all who know him, when I say that in our judgment he has consistently lived up to that standard throughout his long and useful life, and that he has achieved a wonderful measure of success in the sense of that work as defined by Dr. William H. Nichols, who regards it "not as the acquisition of property but the making the most of oneself."

The Presentation

The medal is awarded this year to Dr. Chandler because, in the opinion of the jury of award, in addition to his many valuable contributions to other branches of applied chemistry, he has made such notable advances in the great fields mentioned that he has placed the entire world in his debt and brought added prestige and dignity to the profession of which he is such a conspicuous ornament.

And now, my dear teacher, guide and friend, I cannot tell you how happy I am to be the agent selected to present this beautiful medal to you—I who have received so many favors at your hands, and who would not exchange for any amount of chemical knowledge the inspiration and encouragement derived from your example of a life worth while, and a character, like this medal, of pure gold.

May it be to you a token not only of our high appreciation of your brilliant scientific achievements, but also of our deep and abiding affection! May it bring to you and to those dear to you immeasurable happiness, and may you long be spared to continue your useful work and to be the friend and guide of those setting out on life's journey.

> For, after all, life is a highway,
> And its milestones are the years,
> And now and then there's a tollgate
> Where we buy our way with tears.
>
> It's a hard road and a rough road,
> And it stretches steep and far,
> But it leads at last to a haven of rest
> Where peace and happiness are.

Address of Acceptance

By Charles F. Chandler

Mr. Chairman, Ladies and Brother Chemists: I never was more surprised than when I was notified that the Medal Committee representing the different societies interested in the Perkin medal had awarded it to me. I had never really considered myself eligible, as I supposed the medal was intended particularly for discoverers and inventors of important processes in industrial chemistry. Nevertheless, I accept it with gratitude as an expression of appreciation and affection on the part of my brother chemists.

The selection of Milton C. Whitaker and Marston F. Bogert to speak for me this evening is most gratifying. There are no two men in the chemical profession for whose attainments I have a greater respect or for whose personal qualities I have a greater affection.

After having had the pleasure of presenting this most valued token of appreciation to eleven distinguished chemists, it seems odd to stand tonight in a position of the receiver instead of the giver. It is, however, eminently appropriate that Dr. Bogert should take my place on this occasion, as it falls to the lot of the senior available ex-president of the Society of Chemical Industry residing in the United States to make the presentation.

I happen to have been the first to receive this honor from the Society, there never before having been a foreign president. The experiment must have been satisfactory, as it was soon followed by the election of Dr. W. H. Nichols, then Prof. Ira Remsen and finally by Dr. Bogert. Dr. Nichols and Dr. Remsen are not available tonight, and so the duty falls upon Dr. Bogert as the representative of the Society of Chemical Industry.

I think that there was another reason for selecting Dr. Bogert to make the presentation address. He has had experience at the banquet of the chemists, April 30, 1910, and conspicuously demonstrated his ability to say the kindest and most flattering things about his "old professor."

Dr. Bogert has given you such a comprehensive account of my life and experiences, it is hardly necessary

for me to go very deeply into the subject. I will therefore select only a few incidents which may possibly interest you.

What Determined Dr. Chandler's Career

When I was about fourteen years of age and attending the New Bedford High School, the incident occurred which settled my career for life. There was a young instructor who had a class in chemistry which I attended. He made the subject so interesting that I decided that I must be a chemist. I had a little workshop which I promptly converted into a chemical laboratory, had the tinsmith make me a gas holder and amused my three or four intimate playmates by making oxygen, hydrogen, olefiant gas and various other experiments. The impression which this teacher made upon me has lasted ever since. Two or three years ago I had occasion to give a lecture in New Bedford and I opened it by recalling my school days and I enlarged upon the influence which this young teacher had exerted upon my life. I was subsequently informed that he died while still very young. It was in 1851-52 that I attended his courses. A few days after my lecture I received the most touching letter from his aged widow, who is still living and had been told what I had said of her husband. Her letter brought tears into my eyes.

In 1853 I entered the chemical laboratory of the Lawrence Scientific School and spent a year under the instruction of Prof. Eben N. Hosford, a most charming man. Here I pursued a well-arranged course of instruction in qualitative and quantitative analysis. Here another incident occurred which had a profound influence on my subsequent life. Two strangers visited the laboratory one day and we half dozen young chemists were introduced to them. One was Prof. Josiah D. Whitney, the eminent mining engineer and geologist who five or six years afterward became a very intimate friend of mine; the other was Dr. Charles A. Joy, who had just been appointed professor of chemistry to take charge of the new laboratory at Union College, Schenectady. Prof. Joy told us that he had just returned after a course of four years' study in Germany in the laboratories of Friedrich Wöhler and Heinrich Rose. I subsequently wrote him for further information on the subject of studying in Germany and received a full and enthusiastic account of the advantages not only of studying in Germany but of studying with these particularly distinguished chemists. It resulted in my spending my next year in the University of Göttingen. I was fortunate in being placed at once by Prof. Wöhler in the laboratory for advanced students, which was under his personal direction. I took several courses of lectures and practical instruction, not only in chemistry but in physics, botany and mineralogy.

Companionship With Celebrated Professors

We had a large colony of Americans in Göttingen during the year, most of whom were studying chemistry and some of whom have subsequently held most important positions in the United States. As I was the youngest of them all, it was a great privilege for me to enjoy the companionship which was quite intimate in that small town with such men. One of them, Prof. Goodwin, was a Harvard professor of Greek; another, Prof. Harkness, who was there with his wife, was professor of Greek in Brown University. At the end of the year Prof. Wöhler, who had been a father to me and had invited me frequently to his house, induced Prof. Heinrich Rose to take me into his private laboratory as an assistant, where I spent a year working in the same room with him. He, too, was a father to me, and invited me frequently to his house. His brother, Gustave, with whom I studied mineralogy, was equally friendly. I attended several courses of lectures in general chemistry by Heinrich Rose; industrial chemistry and physics by Prof. Magnus and physics by Prof. Dove. At the houses of the two Roses I used to meet some of the most distinguished scientists in Berlin, particularly Poggendorf and Ehrenberg, the father of microscopy. I also had the great pleasure while in Berlin of spending a couple of hours with Baron von Humboldt in the Royal Palace in Potsdam. Both Wöhler and Rose gave me the most interesting material to work upon in their laboratories either for the purpose of preparing a constituent in some quantity or for making accurate analyses of the minerals. For example, I worked upon the following materials; that is, minerals containing them when the mineral itself is not mentioned: Selenium; tellurium; lithia; thoria; yttria; molybdic acid; tungstic acid; cerite; columbite; tantalite; sarmaskite and yttrotantalite, and other more common materials.

At the end of my second year in Germany, I was asked to put the work that I had performed in the laboratories of Wöhler and Rose into the form of a dissertation, which I did. It was accepted and printed in Göttingen at the University Press in 1856 and I received without examination, in consequence, my degrees of A.M. and Ph.D., or, as they call it in Germany, Dr.Phil.

Begins Professional Life at Union College

On my return to America late in the summer of 1856, I found an invitation awaiting me from Prof. Joy inviting me to come to Union College and accept the position of assistant in the laboratory. This invitation I promptly accepted and on Jan. 9, 1857, I began my professional life. I felt under such obligations to Prof. Joy for having directed me to Europe that I did everything I could in the laboratory for his convenience and comfort. In four months he was called to Columbia College and left at once to take the position. Fortunately for me, the venerable president of Union College, the Rev. Eliphalet Nott, had so much confidence in my abilities that he offered, if I could lecture to the senior class, to put me in charge of the chemical department and give me the title of professor when I was old enough to merit it. I remained at Union College until the fall of 1864; was married, given a house which had formerly been occupied by President Nott and had established courses of lectures in the different branches of chemistry, including agricultural chemistry, and in mineralogy and geology.

Established Columbia School of Mines

Then by a happy accident I was invited by Prof. Eggleston to join him and General Francis Vinton in establishing the School of Mines at Columbia College, which has proved such a great success. The most fortunate circumstance in connection with this embryo school of mines was the fact that we had no salaries. My friends ridiculed and lamented what they considered my rashness in acccepting what seemed such an unpromising appointment. But it turned out a great success. The school not only grew rapidly into a large enterprise but it gave a most powerful impetus to the growth and development of Columbia College, which

although it had been in existence for more than 100 years had only 155 students, almost exclusively residents of New York City. This school of mines, which quickly became a school of every variety of engineering and chemistry, drew students from all over the United States, and spread the name and reputation of Columbia College everywhere, while the graduates, particularly the mining engineers, carried the name of Columbia to Australia, New Zealand, South Africa, South America and Mexico.

If I should continue in this vein to tell you all of my experiences during the sixty-four years that have elapsed since I received my degrees, I should be obliged to keep you here for hours.

Starting at Columbia with no salary at all, with only the expectation of receiving one-third of the fees that might be paid by any student who might attend, we were naturally permitted to take any outside work that was congenial which did not interfere with our duties in the School of Mines. I was soon enabled to take advantage of this privilege by giving afternoon lectures from 5 to 6 at the College of Physicians and Surgeons and evening lectures at the College of Pharmacy and also to accept invitations for professional work of different kinds.

Work for Excise Board

One of the most promising invitations I received came to me from the Metropolitan Board of Excise. The members of this board, not being chemists, were imbued with the idea that there was an enormous amount of adulterated alcoholic beverages in New York and as they had a very high license and a million dollars to their credit in the bank, they started out to put a stop to this adulteration and I was invited to act as their expert to analyze the samples and to appear in the courts as their representative. When they inquired of me how much I would demand for making these analyses and appearing in court, I told them it would depend upon the number they were likely to have. They told me that there were 8,000 liquor dealers and they would certainly average three samples each, so I agreed to a fee of $20 for each case, no matter how troublesome it might be. This they considered reasonable, and when I figured it up I saw a prospective $480,000. They promptly sent me forty samples, upon which I exhausted every possible chemical test. These samples came from Mulberry Bend and other localities where the poorest liquors are probably dispensed. They consisted of brandies, whiskeys, rums and gins. Some were of very good quality, some were not so good, but not a single one contained any objectionable constituent; not one was adulterated. I must confess that I was not much surprised, because I had had some previous experience in making such analyses, especially for the Vermont State Liquor Agency, and I knew that the newspaper stories of adulterated and poisonous liquors were without foundation. I received a check for $800 according to contract and never another sample for analysis, and I charged $479,200 to profit and loss.

Kerosene Industry

I have been told that some members of your committee were of the opinion that my work in putting an end to kerosene accidents and stabilizing the manufacture and the quality of kerosene was my most important work, and I will give you a little account of that and then bring my remarks to a close.

In the year ended Oct. 31, 1869, there were ninety-eight fires caused by kerosene accidents in New York City, and thirty-one in Brooklyn. There were fifty-two persons burned to death in New York City from the same cause, mostly women and children. It was generally supposed that these accidents were due to the fact that kerosene consisted of hydrocarbons, similar to those of camphene and burning fluid, which were known to be inherently dangerous and which could not be made safe. When this matter was called to my attention, I said at once, "Kerosene can be made safe," and took up the investigation of the subject at once.

Manufacturers of kerosene and chemists had decided that all that was necessary to make the oil safe was to separate the lighter oils benzine and gasoline. And I believe that they did so. A standard of quality had been adopted by them. The kerosene oil must not evolve combustible vapor at 100 deg. F., and must not take fire below a temperature of 110 deg. F. On purchasing seventy-eight samples in shops in the city, I found that one sample was pure naphtha, while every one of the seventy-eight others was adulterated with naphtha. Not one of them came up to the standard of the manufacturers. I had a sample of real kerosene for comparison which I obtained from the works of a friend of mine, Dawner of Boston, which had a flash point of 109 deg. F. and a burning point of 128 deg.

Report on Kerosene Spread Broadcast

Just as I finished my experiments there was a terrible accident in New York in which a mother and child were burned to death. I sat up all night and wrote my report. It was manifolded at the Board of Health and given to all the papers, in which it was printed in full, and later published all over the country. The Board of Health of New Orleans had it printed and left a copy at every door. It was quoted in Berlin and in Rome. On Jan. 21 a supplementary report was made showing the temperatures reached in twenty-three house lamps, of glass and of brass, of different sizes, after periods from 1 to 7 hr. After 1 hr. the highest was in a brass lamp, 100 deg. F., the lowest in a glass lamp, 77 deg. F. After 7 hr. the highest was in the same brass lamp, 91 deg. F., the lowest in a glass lamp, 78 deg. F.

The investigations were continued, and later in the year a third report was made containing the following additional results, with a new collection of samples from retail shops in New York City:

	Samples
1. Safe oils complying with requirements	21
2. Dangerous oils, flash point below 100°	280
3. Still more dangerous, flash point below 100°, burning point below 110°	306
4. Pure naphtha	29
Total number of samples	636

A fourth investigation was made and reported, March 18, 1891, of a much more elaborate character which covered 110 printed pages. This was published and Charles Pratt asked permission to print 10,000 copies, placing an advertisement on the cover of his famous extra safe oil, known as Pratt's Astral Oil, which flashed at 125 deg., and burned at 138 deg. F. Permission was cheerfully granted.

The board adopted a sanitary ordinance limiting the sale of oil having a flash point below 100 deg. or a burning point below 110 deg., and appointed inspectors and equipped a testing laboratory, and before long kerosene accidents became very rare, and when they did occur generally resulted from kindling the fire with kerosene

or some other kind of criminal carelessness. Not long after this I was engaged, in company with Prof. Silliman, to act as an expert witness in a suit brought by infringers by Downer & Co. of Boston. This company had worked on oils obtained from the destructive distillation of coal, and also on petroleum. By employing a special process they produced, among other products, two specially high test oils: Downer's Standard Kerosene, flash point 115 deg., burning point 128 deg.; and Downer's Mineral Sperm, flash point 262 deg., burning point 300 deg.

Combustion

I will quote here a few paragraphs from a lecture on "Combustion" which I gave before the American Institute Jan. 5, 1872, immediately after the great fire in Brooklyn which was so disastrous to life.

"Naphtha is not explosive; vapor of naphtha is not explosive; it is a mixture of naphtha vapor and air, in certain definite proportions, which is explosive. If, in experimenting, we do not hit the proper proportions, we fail to produce an explosion. Any oil that will emit an inflammable vapor at any temperature below 100 deg. F. is liable to form explosive mixtures of vapor and air, and is dangerous. I know of no process by which the lighter products of petroleum, gasoline, naphtha and benzine can be made non-explosive or safe, nor do I believe that there is any such process. If any oil takes fire at ordinary temperatures, or below 110 deg. F., it is proof positive that it is dangerous, and no argument or experiment can prove anything to the contrary.

"This coat on its iron frame is a good representation for our purposes of a victim to kerosene. I will drench him with good kerosene; you see now that though I hold a candle to him he is in no danger. I will now throw a little of Smith's 'Safety Oil' upon him; you see the moment the candle is brought near him he bursts into flames. I will save the poor wretch from a painful death by bringing the Babcock Fire Extinguisher to bear upon him. I have put him out; but were he human his days would be numbered, as a painful death would be sure to follow such frightful burns as those he has suffered from Mr. Smith's safety oil. It is said, and I believe with truth, that the burning of a square foot of the human body is sure to cause death.

"Before leaving this portion of the subject, I want to show you how safe it is possible to make petroleum oil. I have here a pail containing 3 gal. of Downer's 'Mineral Sperm Oil.' Into it I will plunge this mass of cotton waste till it becomes saturated with the oil; now as I raise it you see it is dripping with the oil. On holding the candle to the oily mass you see I have considerable difficulty in setting it on fire, but by heating it in one spot I shall finally heat a portion to a temperature above 300 deg. F., its burning point, when it will take fire. Now you see I have succeeded in starting combustion, and the burning oil quickly heats the rest of the mass till we have a flame 10 or 15 ft. high. You need not feel alarmed, for I have the flames entirely under my control. I will now plunge the burning mass into the pail of oil; you see it is at once extinguished. The 'Mineral Sperm' is actually a fire extinguisher.

"But this oil will stand a much more severe test. Here we have a large pan of oil on a water bath. These two large alcohol lamps have raised the water to boiling; you see the steam escaping from this vent; the oil is at 212 deg. F., 112 deg. above the standard flashing point and 102 deg. above the standard burning point of safe oil. Yet you now see that this mass of cotton waste which was saturated with the oil and was but a moment ago wrapped in flames, is now quietly extinguished. The 'Mineral Sperm' is a fire extinguisher even when heated to 212 deg. F. Am I wrong in saying it is practically as safe as whale oil?"

Work on Petroleum Oils

The Standard Oil Co., recently organized, manifested a great interest in my work on kerosene, and employed me as an expert in law suits, brought against them by persons who erroneously believed them using their patents, generally worthless, without their consent. Some years later when what was known as "Ohio oil" was obtained in Ohio, Indiana and Illinois in considerable quantities, the company received word from its German associates that the German Government had been informed by rivals that while the Standard Oil Co. was supplying the American market with the superfine Pennsylvania oil, it was sending to Germany the poor, offensive "Ohio oil." In consequence, the Imperial Government was about to permanently forbid the importation of this poor oil into Germany. A high officer of the Standard Oil Co. came to me and begged me to go at once to Germany and convince the German Government that the Ohio oil which his company exported was first purified by the process invented by Herman Frasch. This was one of the inventions for which your committee, a few years ago, awarded to Frasch the Perkin medal.

President Low granted me a leave of absence, and I immediately visited the great works erected at Whiting, Ind., for the special treatment of Ohio oil by the Frasch process. The impurities which had rendered the oil and all its products so offensive were certain compounds of sulphur, of which element the oil contained about 1 per cent. Frasch's process consisted in first dividing the crude oil by distillation into three fractions:

1. Lighter constituents, gasoline, naphtha and benzine.
2. Medium oil for lamps.
3. Heavy oil for lubricating and paraffine.

These three fractions were then entirely freed from the sulphur compounds by distillation in huge stills, while mixed with large quantities of oxide of copper, with constant stirring. The effect was magical. Not a trace of the offensive odor was retained by either of the products.

I met at the Whiting works the chemist in charge, Dr. William M. Burton, a Heidelberg graduate. He showed me everything and answered every question. When I told him that I was going to Berlin to explain the situation, a longing look overspread his face, and he remarked that he had not been in Germany since he graduated. I caught the look and asked him if he would like to go with me. He replied that he would give anything to go. I found no difficulty in persuading the company to give him a leave of absence, and so I had a most agreeable and useful companion.

Before I sailed I visited the works at Olean, N. Y., at Philadelphia, and at Brooklyn. So there was nothing in the treatment of petroleum that was not imparted to me. We went off together. It seemed wise, before we called upon the representatives of the government, to

visit and satisfy the men who would be most likely to be consulted by them. So after visiting the representatives of the Standard company in either Bremen or Hamburg, I have forgotten which, we went to Karlsruhe and explained the whole matter to Dr. Engler, the German expert on petroleum, giving him samples of the Ohio kerosene, and explaining how he could prove the absence of sulphur, if the entire freedom from offensive smell did not satisfy him.

Convinces German Government of Purity of Ohio Oil

Then we went to Zurich and explained the matter of Dr. Lunge, the distinguished industrial chemist. On arriving in Berlin, we adopted the same tactics with the Imperial Health Department, with the same success. With all these parties I had enjoyed an acquaintance for some years, so we were cordially received and our statements readily accepted. An hour spent with Count Posidowski, the Imperial Minister of the Interior, settled the business.

A few years later I was sent to Germany to again try and prevent the threatened establishment of an extra high standard for all imported oils, to be considerably above "100 deg. flash and 110 deg. burning." This time I did not have the company of Dr. Burton. As before, I first went to Karlsruhe to argue the matter with Dr. Engler, but to my discomfort I found that he was in the Austrian Tyrol, near the glaciers. There was nothing to be done but to follow him, so I crossed Lake Constance and took the train for Vienna, leaving it the next morning at Bludence. Here I hired a man to drive me to my destination, which was a day's journey. At noon we stopped at a cross-road village for lunch and to change horses. After eating my simple lunch of "Butterbrod" and "Schweitzerkäse" and drinking my "Bayerisch." I started out to see if there was anything interesting in the village. Strolling into the country store, I inquired of the proprietor in German if he sold petroleum. He replied, "Yes, indeed." I inquired what kind and he said "Amerikanisches." "Is it not much more expensive than that from the neighboring wells in Rumania and Galicia?" "It is, indeed," he replied, "but it is so much purer; it will burn in any lamp without smoking, while the other oils will burn only in a special lamp." He assured me that the peasants willingly paid the extra price. This interview gave me my trump card. Engler saw the point at once, and so did the Imperial Board of Health at Berlin, and so did Count Posidowski. I made it clear to them all that if they raised unnecessarily the standard of oil to be permitted to enter Germany, the only result would be that the Standard Oil Co. would get 50 gal. of such oil out of 100 crude, while they were getting 60 at that time. It would have no real advantage, while the German people would pay as much for the 50 gal. as they were paying for the 60 gal. He saw the point and that was the end of it.

Some years later a bill was introduced in Parliament to accomplish the same result in order to help the Scotch manufacturers, who made a comparatively small amount of kerosene from the Bog Head mineral. I was in Paris at the time and in response to a telegram from the Standard company I went before a parliamentary committee and made the same argument. A member from the Bog Head district, who was working for the bill, had a copy of my last report of 1871 before him, identified me as the author, and then asked me if I had not intimated therein that "the higher the flash point, the safer the oil." I replied that I had, but at that time we had not had as much experience as at present. Time had shown that "100 deg. flash" was sufficient to insure safety, and that that grade of oil was generally used in the United States and exported all over the world, and that lamp accidents were very rare.

Further I reminded him of an English nobleman who lost his life by the explosion of an extra high test oil, because the oil evolved just enough vapor to make an explosive mixture with the air in the lamp, while the 100 deg. flash evolved enough vapor to render the air in the lamp non-explosive.

Several distinguished English chemists, Sir Henry Roscoe, Sir Boverton Redwood and others gave similar testimony, and the bill never passed the committee.

I should like to add here that my friend Dr. Burton invented a most successful process for breaking up heavy oils into gasoline substitute for motors. He distills and condenses under a pressure of 90 lb., the heat required being sufficient to break up the molecules of the heavier oils into smaller molecules which constitute the lighter and more volatile gasoline, benzine and naphtha. There are now in use 1,000 sets of his stills and condensers, 240 of them at Whiting.

The Metropolitan Health Department of New York

In 1867 Dr. Elias Harris of the New York Health Department came to see me and told me that the Commissioners were not chemists and did not realize how much chemistry had to do with the public health and did not care to devote any portion of their income to this subject. He asked me if I would be willing to do some work for the department without charge. I promptly accepted his invitation and interested myself at once in a great variety of subjects, most of which I shall have to omit discussing.

Water

There are two or three matters, however, which interested me very much; one of these was water. I began analyzing the Croton and Ridgewood waters every week during the three or four summer months, and I continued for several years, either myself or when I became president of the Health Department through Prof. Waller, to keep informed with regard to the water supply of these two cities. I found that these waters were then and have been ever since among the purest waters supplied to any cities in the world. I do not believe that a case of sickness was ever caused by either one of them. General Green, who was at one time the engineer of the Croton aqueduct, was so interested in my work that he had me appointed consulting chemist for the department, and took me all over the Croton watershed that I might become familiar with the sources of the water. It is a source of constant regret to me that ill-informed persons, even physicians, are so ignorant on this subject that they advise families not to drink the Croton water unless it has been filtered or boiled or both, and the result is that millions of dollars are spent in New York every year for bottled waters, not only in families who can ill afford the expense, but in downtown business offices. During the fifty-six years that I have lived in New York, I have used the Croton water in my family without filtering or boiling, and never has anything occurred to lead me to suppose that the water was not

perfectly satisfactory and wholesome in every respect. Another phase of the water question occupied my attention for a year when at the request of the New York Central R. R. Co. I studied the subject of boiler corrosion in locomotives, boiler incrustations and feed water. I began this work at Union College and completed it in the School of Mines, publishing my results. I analyzed numerous specimens of incrustations, finding that some of them consisted of carbonate of lime; others of a mixture of carbonates of lime and magnesia; others of sulphate of lime. I also investigated the different brands of boiler medicines, most of which were frauds and the one which seemed to be an excellent one was sold to the railroads for five times what it cost to make, and the engineers couldn't bring their trains in on time unless this particular medicine was supplied by a particular firm. In the end, I analyzed all the feed waters employed on the road between Albany, Buffalo and Niagara Falls, classified them as to quality, indicating those that were too bad ever to be used and causing the water stations to be abandoned, and directing the best choice to be made among the others.

Hudson River Water

I was called upon by the Water Commissioner of Albany to investigate the waters of the Hudson River, to ascertain whether it would be safe to take the water above Albany and below Troy to supply the city, as they had found it almost impossible to procure an adequate source of supply within reasonable distance and at such cost as the city could afford to pay. I took up this investigation with great doubts of the fitness of this water for the city supply. I made the most careful investigations and analyses and was surprised to find that there was no reason why this water could not be used in the city of Albany. I sent in my report in 1872, stating my conclusions, with a special discussion of the destruction of the sewage contamination of large rivers caused by dissolved oxygen. I had obtained a great deal of information on this subject from the annual reports of the British Water Commissioner. The report was published and indignation meetings were held in Albany and no end of abuse was poured upon my head. The Water Commissioners were very sensible men, however. They said there was no sense in abusing Chandler; disprove his facts, meet his arguments or keep quiet. My facts could not be disproved and my arguments could not be met and consequently the Water Commissioners put up the pumping station, supplied the water to Albany, and in a short time the Health Officer of Albany informed me that the water was entirely wholesome and satisfactory.

In 1885 it became necessary to increase considerably the pumping facilities above Albany, and the Water Commissioners wrote me, calling attention to the fact that since I made my first investigation and report in 1872 bacteria had become fashionable and were now supposed to be terrible creatures capable of producing all kinds of diseases, and whether I cared to revise the opinion which I gave them thirteen years before. It happened that I was quite familiar with what had been published with regard to bacteria, having quite a library on the subject and having had occasion to make myself specially familiar with them in order to prepare an article on fermentation for Johnson's encyclopedia about 1874, so I wrote the second report on the waters of the Hudson River, which was published in Albany in 1885, containing a discussion of possible bacterial contamination of water.

Fourteen years ago while in Europe I was cabled to look up the ozone treatment of city waters. Accordingly, I visited Berlin, Paderborn and Paris, where experiments had been carried on. At Paderborn the process was in full operation, although the water supply was entirely above suspicion. The water descended slowly through a wide circular cylinder, while the ozonized air bubbled up through it. The effect was marvelous. The ozone seemed to destroy the organic matter, which though minute, was sufficient to conceal the true color of the water, for when the treated water was poured into a large snow white vat, it was very distinctly blue.

Saratoga Waters

In the early years of my residence at Union College, I became interested in the Saratoga waters. I found a great diversity of opinion as to the nature of these waters, some local physicians telling their patients that there was such a great difference in the waters that it was not safe for them to drink them except after the physician had carefully diagnosed their cases; had directed them as to which waters they should imbibe, what quantities of each, and at what times of day. The owners of the Star Spring employed me to make a careful analysis of their water and soon it became the fashion to have the waters analyzed by me, as the waters contain a great variety of constituents, including small quantities of iodine, bromine, baryta and lithia, etc. I had to charge a good round figure, which those who could afford it cheerfully paid, and as I was extremely anxious to analyze all the waters for those who could not afford to pay my fee, I made the analyses gratuitously, including springs and artesian wells. I analyzed about a dozen different springs in Saratoga and three at Balston. Instead of the waters differing from one another, I found that they all contained the same constituents, counting out one or two sulphur waters in out of the way places which I never took the trouble to analyze. The total amount of solids varied from a minimum of 302 grains in one United States gallon to 1,184 grains, the latter being the amount in the Balston artesian lithia well, which was bored over 600 ft. There is an interesting story about the High Rock Spring at Saratoga. It is the oldest known spring there and it consists of a volcano-shaped rock about 4 ft. above the level of the surrounding ground with a hole or crater in the center supposed at that time to be of almost unknown depth. This hole had a diameter at the top or mouth of 8 or 10 in. and the water rose to within about a foot of the top. Saratoga was first visited by a white man when Sir William Johnson went there in 1767. He was told by the Indians that according to their traditions the water formerly rose and overflowed regularly, continuously, but not within their recollection. This must evidently have been the case, for the High Rock is composed of tufa, carbonate of lime and contains the impressions of leaves and the shells of snails here and there. It had evidently been formed gradually by a deposition of carbonate of lime from the water, which is a common occurrence with this class of waters. After a time during my association with Saratoga, this spring changed hands and the enterprising purchaser decided to make the water resume its old habit of overflowing

the rock. In order to do this, he had oblique holes drilled on different sides around the edges of the rock toward the center. He then introduced wedges and succeeded in detaching the rock from its base. He then put chains underneath and hoisted it off one side. Then they enlarged the hole up through which the water came and went down expecting to find some leak which had prevented the water from rising any higher, and which they intended to close. They found beneath the High Rock a layer of tufa 7 ft. thick, including some muck, below that they found 2 ft. of tufa clean, below that 1 ft. of muck and below that again 3 ft. of tufa. Just below the rock itself they found four well preserved logs put crosswise at right angles to make a curb for the spring, which must have been placed there before the High Rock was formed, and, finally, at a depth of 17 ft. they found a considerable quantity of half-burned embers and charcoal, showing that at some previous time visitors had made fires before that 17 ft. of material had been deposited.

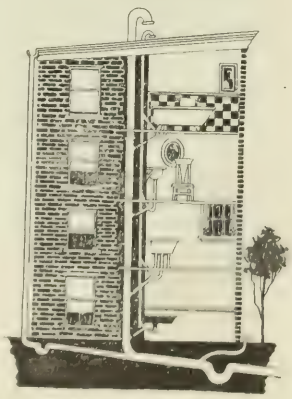
An enterprising citizen of Saratoga was very anxious to ascertain when those fires had been made, and remembering that the botanist ascertained the age of a tree by making a cross-section of the stem and counting the lines or rings from the center of the circumference ascertained the number of years it had been growing. He took a piece of the High Rock, smoothed it against a grindstone and found it showed 81 lines to the inch, so he said it must have taken 3,840 yr. to form. The following table shows his figuring:

THE HIGH ROCK

	Yr.
The High Rock 4 ft.—81 lines to in.	3,840
Muck and tufa 7 ft.	400
Tufa 2 ft.—25 lines to in.	600
Muck	130
Tufa 3 ft.	900
Total	5,870

According to his education, the world had only existed 4,004 years before the Christian era, and 1,870 years after the Christian era, or 5,874 years in all. As the fire was made 5,870 yr. in the past, it was made 4 yr. after the creation. Consequently, there was no one living on the face of the earth excepting Adam, and he was four years old. I hope you will pardon my frivolity in presenting this ridiculous proposition to you, but it went the rounds in Saratoga.

There is one other interesting matter connected with the Saratoga Springs. Some years ago a sanitarium near the Hathorn Spring set up a pump, and drew large quantities of water from a tube of some depth, with the result that the Hathorn well was very seriously affected. A law suit resulted in which my testimony and that of others was taken in favor of Hathorn, with the result that the sanitarium was enjoined. At or about the same time, a company began to bore numerous wells some little distance from the springs, introduce steam pumps, commercialize the carbonic acid gas, and permit the water to run to waste. In a short time the springs began to show the disastrous effects. The waters no longer spouted from the spouting springs, the others no longer came to the surface, and pumping had to be resorted to. In addition to this the diminished pressure of water in the springs permitted fresh water to permeate and dilute them.



CHANDLER PLUMBING SYSTEM

Again I was called as an expert, and testified to the ruinous effect of this pumping. The company produced experts who declared that it was absolutely impossible for this pumping to have any effect whatever on the springs, and that the falling off of the springs must be due to natural causes. The judge, however, was a second Solomon. He directed the defendants to stop pumping for 48 hr. to decide the question, and ordered the sheriff to see that the order was obeyed. Within 24 hr. the whole town gathered around the Hathorn Spring to see the water again rising, brilliant in the sun with gas bubbles, and overflowing the large glass cylinder placed over the spring. In the end the state bought all the springs and established a State Reservation.

Lead Poisoning

The lead question in drinking water came to my attention at an early day. Physicians reported cases of lead poisoning. I will mention a single example. An elderly gentleman's case was diagnosed as lead poisoning. No probable source of the lead could be suggested till the doctor interviewed the cook, and learned that her first duty in the morning was to place the old gentleman's "wheaten grits" cereal in a bowl, draw water upon it and after a while boil it. This fact suggested lead in the water. My attention was called to the subject and I found that water which had stood all night in the pipe of my own house contained a little lead, which might, as lead is a cumulative poison, ultimately produce serious results, if such water were often used. Looking further into the matter, I found that owing to the low pressure in the water pipes a great many houses were provided with pumps, and tanks to supply the upper stories. Examination of the tanks developed the fact that they were usually lined with lead, and the water thus became contaminated.

Examinations were also made of Croton water which had been in contact with lead for different lengths of time, under usually occurring circumstances, of which the following are the results:

1. A gallon of Croton water from a lead-lined cistern, in which it had stood several weeks, was found to contain 0.06 grain of metallic lead.

2. A gallon of water which had remained 6 hr. in the lead pipes of my residence yielded 0.11 grain metallic lead, a considerable portion of which was visible to the eye, in the form of minute white spangles of the hydrated oxycarbonate.

3. Water drawn from one of the hydrants of the School of Mines laboratory, in the middle of the day, when the water was in constant motion, yielded traces of lead. This water reaches the school through 100 to 150 ft. of lead pipe.

These results indicated the source of many hitherto unaccountable cases of lead poisoning, and are of a character to alarm the residents of New York, and lead them to adopt precautionary measures for protection against this insidious cause of disease.

A celebrated case occurred in the royal family of France, at Claremont, where one-third of the persons who drank of the water were affected. This water contained only $\frac{1}{10}$ grain of lead in a gallon. As little as $\frac{1}{100}$ grain of lead to the gallon has been known to

produce palsy in persons who habitually drank it. It is a great pity that the peculiar advantage of lead as a material for the manufacture of water pipes is more than counterbalanced by the danger of lead poisoning. These last paragraphs are quoted from a letter delivered before the American Institute in the Academy of Music, Jan. 20, 1871.

This subject attracted a great deal of attention at that time. The Board of Health put an end to the use of lead-lined tanks and the public was warned against drinking water that had stood long in the pipes. About this time tin-lined lead pipe was invented. It was made by casting lead around a hollow cylinder of tin, and then drawing the mass down to a pipe of the desired size. I found that the heat of the melted lead was liable to soften the tin lining to such a degree as to alloy it with the tin even clear to the inner surface of the tube. A suggestion of mine overcame this difficulty. A separate hollow cylinder of tin was placed in a surrounding cylinder of lead of such size as to leave nearly $\frac{1}{4}$ in. space between the two. Then melted solder was poured between the two cylinders; they were perfectly united without melting the tin perceptibly, and a perfect tin-lined pipe was produced. I used this pipe throughout my country house at West Hampton, and one of the spring companies at Saratoga employed it for a deep spring, using a very large-sized pipe. A test of the proper condition of the pipe was easily made by cutting off a section about 1 in. long, holding it in forceps and carefully heating it over a bunsen burner. If it was in good shape, the solder would first melt, as could be seen by the eye, and the tin tube could be shaken out in a sound condition. If, on the contrary, the lead had alloyed the tin, the entire lining sloughed off on heating. Special joints were devised and the invention was a complete success. But the cost of plumbing was considerably increased, both for material and labor, and the invention never came into general use.

Poisonous Cosmetics

Before I leave the subject of lead poisoning I must say a word with regard to the poisonous cosmetics which I examined in 1869. Hair tonics, washes and restoratives were much advertised and sold. The following are the results of my examinations of those sold in New York City. Only one was free from lead, that was Hoyt's Hiawatha Hair Restorer, which was an ammoniated solution of nitrate of silver, and harmless. Here are the others:

TABLE SHOWING GRAINS OF LEAD IN ONE FLUID OZ.

Clark's Distilled Restorative for the Hair	0.11
Chevalier's Life for the Hair	1.02
Circassian Hair Rejuvenator	2.71
Ayer's Hair Vigor	2.89
Prof. Wood's Hair Restorative	3.08
O'Brien's Hair Restorer America	3.28
Gray's Celebrated Hair Restorative	3.39
Phalon's Vitalia	4.69
Ring's Vegetable Ambrosia	5.00
Mrs. S. A. Allen's World's Hair Restorer	5.57
L. Knittel's Indian Hair Tonique	6.29
Hall's Vegetable Sicilian Hair Renewer	7.13
Dr. Tebbett's Physiological Hair Regenerator	7.44
Martha Washington Hair Restorative	9.80
Singer's Hair Restorative	16.39

These fluids consist of an aqueous solution of acetate of lead, generally containing a sediment of flowers of sulphur. They are to be well shaken before use and when applied at intervals to the hair are said to "gradually restore the originally youthful beauty and color." Six lotions or washes for the complexion were examined, and one contained corrosive sublimate and sulphate of zinc. Seven enamels for the skin were examined; three contained oxide of zinc, three others contained carbonate of lead and only one of the enamels submitted was free of lead.

The Plumbing System

I should be very glad to have had time to explain the improved system of plumbing which resulted from the experimental set of plumbing arrangements which I erected at the Board of Health building, where with a kitchen sink, butler's pantry sink above it, a wash bowl above that, and a bath tub above that, all with glass traps for ready observation, it was easy to demonstrate the absolutely unsafe condition of the plumbing not only in New York but everywhere else in this country.

The result of this was an improvement resulting in carrying the soil pipe through the roof, of undiminished caliber; the back airing of all traps by means of a separate pipe running through the roof; the running trap between the house and the street sewer; and the inlet for fresh air between the house and this trap. This system was approved by the plumbers and fixed by law, and was placed under the control of the Board of Health. It was generally adopted throughout the country, and there was no more talk about sewer gas as a cause of disease. Microbes took its place. Patent traps were not accepted as substitutes for good old-fashioned "S" traps. By the way, I have just learned from A. E. Hansen, hydraulic and sanitary engineer, who is adviser to the Master Plumbers' Association, that an effort is now being made to force the plumbers to adopt a "patent trap." To adopt this would be a crime.

Brief Mention of Other Activities

There are many other topics to which I would delight to call your attention, such as:

My connection with the first production of oleomargarine, that cheap, wholesome article of food which has been so handicapped by the government.

Introduction of cheap water gas here and in Boston, and sustaining the Lowe process for its manufacture.

My study of sugar refining in Europe in 1869, and the Hunters Point nuisance.

I should also enjoy telling you of the splendid work of Miss Louisa Lee Schuyler in rescuing 2,500 pauper insane from the state poorhouses and placing them in state insane asylums, where they had some chance of recovery. And of Mrs. Kinnicutt's very successful campaign to secure an efficient street cleaning department.

In both of these enterprises I was honored with the responsibilities of president of the associations which the ladies organized, but the credit of these great reforms belongs entirely to them.

I must also call attention to the lion's share of the work in my report on the air of the subway, published when that public utility was first opened and certain individuals erroneously pronounced the air therein so unwholesome. Dr. Floyd J. Metzger performed the laborious portion of the investigation.

I wish I could take the time to tell you how much certain members of this Chemists' Club have contributed to the success of the City and State Health Departments: Elwyn Waller, Samuel A. Goldsmith, Edward G. Love, Arthur H. Elliott, Charles E. Munsell and others whose names I do not just now recall.

In conclusion, let me express my appreciation and warmest thanks to the members of your committee, who have considered me deserving of this medal.

Teaching Chemical Engineering in Columbia University

Outline of the Chemical Engineering Curriculum at Columbia University as Instituted in 1915—Theory and Practice Combined in a Manner Considered to Meet the Demands of Industry

By ELLWOOD HENDRICK

COLUMBIA UNIVERSITY, founded in 1754 as King's College by royal grant of that second scion of the house of Hanover who called himself "Shorsh," is now the most largely attended university on the continent. Indeed we believe that it holds the world's record for attendance, the registration for this year being about 25,000. The fact, however, is of less importance to us than that Columbia addresses itself more particularly to post-graduate studies than most other American institutions of learning. With this in view, and bearing in mind its development as a university, the authorities decided that the engineering professions were of a learned nature, and that the same measure of preparation—but not the same preparation—is necessary for any of its seven engineering courses as is required for law, divinity, or medicine. The question whether, for instance, a chemical engineer should be an astute pipe-fitter or a cultured professional man with all the consciousness of professional obligation and with training in pure science to understand the philosophy of his work as well as its details was answered very clearly by the Columbia authorities. And its present engineering schools which require a minimum of six years from college entrance are founded upon the theory that engineering is a professional institution. This must not be taken to mean that years of drilling in Latin and Greek are called for. These studies remain optional with the student. What the School of Chemical Engineering demands is at least three years' special preparation in pure science in college, to meet its requirements. A Bachelor's degree in arts without this preparation is inadequate. These requirements involve a working familiarity with calculus and modern languages, and a good grounding in general and inorganic chemistry, as well as in qualitative analysis and in physics. They call for sufficient preparation to enter an advanced physical laboratory course. High school physics and chemistry courses are inadequate.

Pre-Engineering Course in the College

The College gives a pre-engineering course of three years which leads to the entrance of any of its engineering schools, but a Bachelor's degree in science is obtainable only after one year of additional study. The pre-engineering studies cover a course in general chemistry and qualitative analysis, drafting, descriptive geometry, English, history, and economics, mathematics and modern languages, philosophy, physical education, physics and mechanics, with surveying as an elective.

In the Chemical Engineering School there follow three sessions per year instead of the ordinary winter and spring sessions. That is, it is held that the students are men, and that two to four weeks constitute enough of a vacation during hot weather, so that they are required to work during the summer as well as in terms. The same measure of work is demanded for a diploma that was heretofore required for a Doctor's degree; and a Chemical Engineer's degree from Columbia at present indicates that its possessor has completed as much study as is required anywhere else for a Ph.D. degree.

Of course it stands to reason that the degree of Ch.E. indicates a different design in training from that of Ph.D. The Chemical Engineer is prepared to be first a plant foreman, then superintendent, and then manager. The Ph.D. course, on the other hand, is one in which the research idea dominates, and in the industrial field it points toward work in the development of new methods and new articles for chemical manufacturing.

The three-year graduate curriculum for the Ch.E. degree is a full one, as has already been intimated, and it includes three courses in physics, three courses in electrical engineering, four courses in mechanical engineering, three courses in civil engineering, two courses in metallurgy, etc., also courses on chemical factory equipment, factory design, factory management, applied colloid chemistry, and treatment of water and sewage. Not the least important are the two summer requirements and the theses. In the first summer the student spends two weeks in factory inspection, and follows this by eight as a workman in some factory. In the second summer the student works in the Chemical Engineering Laboratory for six weeks, using large-scale apparatus.

From the foregoing we do not learn of a number of features that are included under more general headings. Thus the introduction of biological chemistry in the industrial organic and colloid courses is made an important part of these. It is the opinion of many organic chemists that the use of micro-organisms in organic synthesis is capable of remarkable development, and that it will soon play a far more important part in the economics of chemical industry than at present. This and other subjects are presented to the students in such a

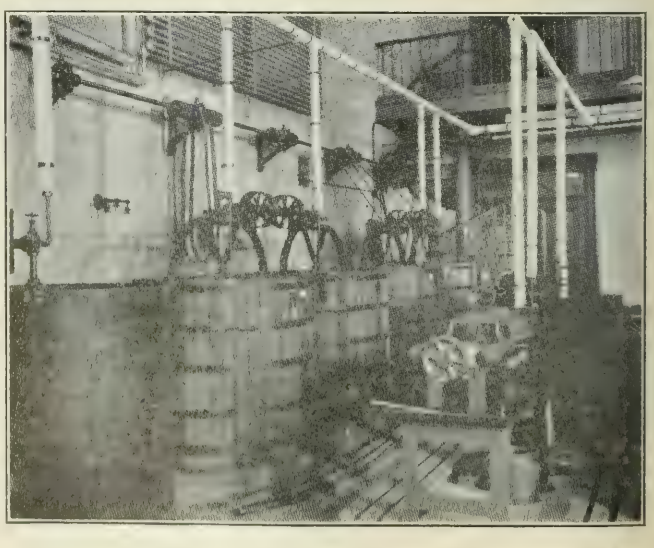


FIG. 1. FILTER PRESSES, PUMPS, SIPHONS, TANKS, AGITATORS, ETC.

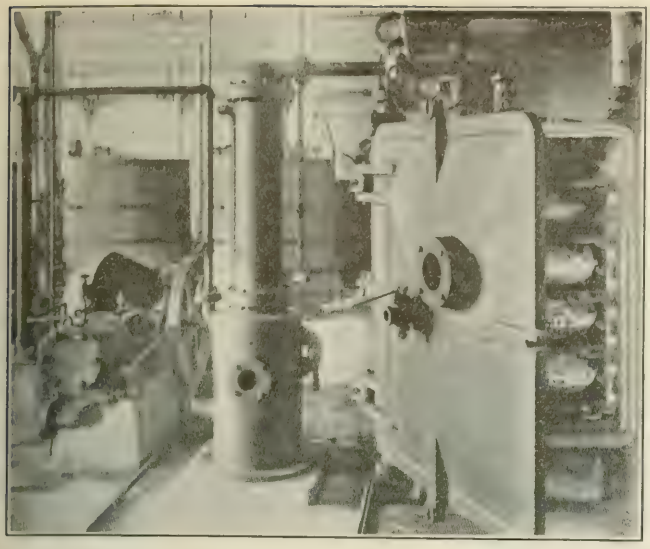

FIG. 2. VACUUM SHELF DRIER, CONDENSER AND PUMP, 42-IN. SHELVES

manner as to enable them to carry on their studies along these lines whenever it may seem profitable to do so. The laboratory has all facilities for biological work. Again, in electrochemistry a great deal of the time devoted to its study is within the organic field. Here also the student gets a medium of research which proves itself constantly in the solution of organic problems.

Enthusiasm of the Students

During the six weeks' summer work in the chemical engineering laboratory at the end of the second year, it is required of each student that he make ten preparations in quantity. This year the students asked for an extra week to complete their work—and they were not availing themselves of labor union hours either. They were working all day and every day. The fact that the course is known to be advanced and severe has caused a group of "selects" to undertake it, and, according to one of the professors, "they fairly eat up work." The Chemical Engineering Laboratory has a great deal of small-factory-scale apparatus. We noted, in passing through, a Kelly, an Oliver, and an Industrial Filtration press, all three gifts this year; of which the same may be said of a Badger drying oven, and a new de Laval separator. We saw a pot still, an autoclave tested to 1,000 lb., a Dopp kettle, a double effect vacuum evaporator, a Pfaudler kettle, and one from Elyria; a Devine drier, a Lummus still, a continuous still, and a Lummus extraction apparatus, a Duriron pump, a small paper beater and drier, a 600-gal. and several 300-gal. tanks and still more. The presence of these apparatuses makes the student familiar with them and their uses, and enables the advanced classes to attack new research problems on an industrial scale under the guidance of the faculty. Through donations of manufacturers who are anxious that students become familiar with the uses of their apparatus the Chemical Engineering Laboratory is becoming almost a Chemical Engineering Exposition!

Carvacrol From Crude Spruce Turpentine

A good example of students' work in the Chemical Engineering Laboratory in which several were engaged was the production of carvacrol from crude spruce turpentine, from a sulphite digester, containing about 85 per cent cymene. This involved roughly ten technical steps as follows: (1) It was steam distilled in a pot still, (2) sulphonated by stirring with 66 deg. Bé. sulphuric acid in a Dopp sulphonator, (3) diluted with water and neutralized with milk of lime, (4) filtered in a Sperry filter press, (5) filtrate treated with soda ash and (6) filtered in a Shriver filter press—to use both types—(7) evaporated to dryness, (8) fused in a Stuart & Peterson fusion kettle with NaOH, the fused mass dissolved in water, (9) acidified with sulphuric acid, and after separation (10) distilled.

Now the recorded yield of the original process was about 60 per cent, but these students, by their care and watchfulness, achieved a yield of over 75 per cent, based on the crude cymene used. Carvacrol is an isomer of thymol, and possesses similar properties. By a new analysis developed during the work it was found that about 8 per cent of their carvacrol *was* thymol. Therefore it is the thesis of another student to develop thymol in the place of carvacrol, from the cymene. That, if it succeeds, will be a noteworthy industrial achievement, for very large quantities of thymol are used.

In the third year, "Chemical Engineering Thesis" takes up six hours per week during the spring session. A satisfactory thesis is required of each graduate, but the research problems in hand are always of an industrial type, and many of them of a major nature.

In addition to students' theses there are several industrial fellowships, and students may be assigned to assist on these whenever feasible. Of such is one on the utilization of sulphite waste liquors which is extremely promising. It is worth while to remember that in the United States and Canada there are daily thrown into rivers, killing fish, and generally polluting their waters, 4,000 tons of material that should be employed in organic chemical industry.

Some Typical Problems

Some of the typical thesis problems on which young men are laboring this year are:

1. Silica gel and its adsorbing qualities.
2. Commercial production of benzoic acid starting from benzene and not toluene.
3. Prevention of rancidity of artificial butters.
4. Clarification of oils from the colloidal side.
5. Theory of sulphonation: a study of conditions which determine sulphonation.
6. Effort to devise an electrode that will stand between graphite and platinum; an electrode that may be used in an acid oxidizing solution.
7. Production of acetic acid from acetylene without passing through the aldehyde stage.

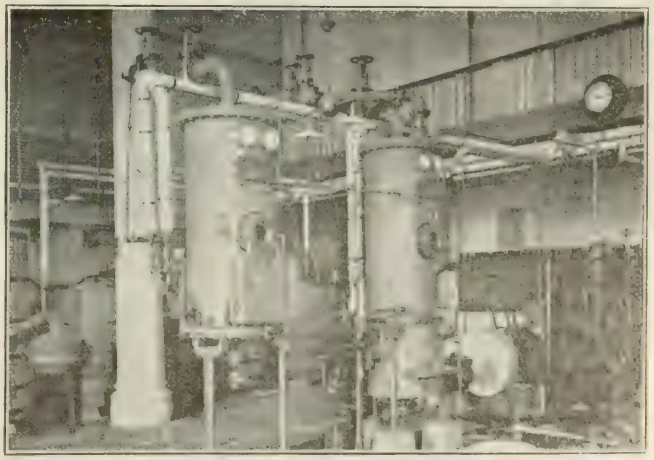

FIG. 3. DOUBLE EFFECT VACUUM PANS (24-IN.) WITH COMPLETE EQUIPMENT—CONDENSER, VACUUM PUMP, CIRCULATING PUMP, SALTING-OUT CHAMBER, ETC.

8. Study of the physical constants of phenol condensation products.

9. Determination of the physical constants of oil shale and its oil on which apparatus may be designed, including heat conductivity, and specific heat of shale, and the specific and latent heat of shale oil.

A typical group of problems given to students of the Engineering course is shown in the following:

(Show Calculations)

1. In the steam distillation which is made from the reducer after the completion of the reduction of nitrobenzene to aniline, how many pounds of 3-lb. steam will be needed to remove in seven hours 900 lb. of crude aniline to the condenser and receiver? (Use 50 per cent over the theoretic amount to care for radiation losses and the slowness with which the last traces distill over.) (Vapor pressure at 98.5 deg. C. is for aniline 45 mm., and for water 715 mm. The latent heat of aniline is 104 calories.)

2. How many gallons of cooling water entering at 70 deg. F. and leaving at 190 deg. F. will be needed for use in the condenser in connection with the above operation?

3. If a copper coil condenser of thin pipe, 1½ in. diameter were used, how long should the coil be built?

4. Show a heat flow sheet, including calculations, giving the heat changes involved in the reactions where, starting with 800 lb. of benzene, there is obtained successively 1,200 lb. of crude nitrobenzene and 900 lb. of crude aniline?

It will be seen from the above that the course is for thinking students rather than for memorizing ones. Teaching is done as much as possible through the eye. Long lectures are discouraged, and all lectures are made as informal as possible. Machines and pictures of machines are shown, and many lantern slides are used. The Chandler Museum, to which the old Dean of American Chemistry gave so liberally of his time and substance, is a mine of wealth to the faculty.

The school as now constituted has been in operation since 1915. The first class of 6-yr. men graduated in 1918, and there were but three of them. In 1919 there were seven. The class of 1920 has twenty; 1921, twenty-one, and 1922 has twenty-four. It is now up to the same numerical basis as when it was a 4-yr. course. It would be inconvenient with the present facilities to care for larger classes than 30 for each of the six years. The present students come from all over the world: South Africa, China, Japan, East India, France, Spain, England, Chile, and all parts of the United States. All admit that the course is not too long, and some students are returning for an extra year and the Ph.D. degree.

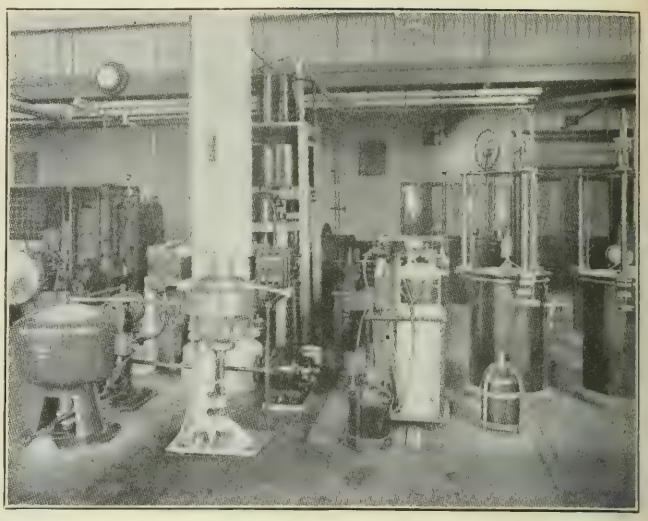

FIG. 5. GENERAL VIEW SHOWING WHIZZER CLARIFIER AND FILTER, WELDING OUTFIT AND GAS HOLDERS

The Faculty of Applied Science of Columbia is headed by the dean, Prof. George B. Pegram, who is also head of the Department of Physics of the college. In the School of Chemical Engineering Dr. Leo H. Baekeland is honorary professor, and gives occasional lectures. He is also a power in council. The executive officer of the department is Prof. D. D. Jackson, and with him is Dr. Ralph H. McKee, also a full professor. In this department are also Dr. A. W. Hixson, Associate Professor and Dr. J. J. Morgan, and Associate Assistant Professor H. B. Faber, with a number of lecturers and assistants having to do specifically with chemical engineering. For all other subjects the school draws upon the great faculty of the university.

New Elmore Process for Zinc-Lead Ores

The new Elmore process for the extraction and separation of lead sulphide from mixed ores, which has been tried out in connection with the ores from the Burma Mines, Ltd., and other ores, is in its main features substantially as follows, according to a note in the *Bulletin* of the Canadian Mining Institute:

"When a mixture of lead and zinc sulphides is treated with concentrated sulphuric acid at 100 deg. C., under proper conditions as regards fineness, proportion, time of contact, etc., the lead sulphide is converted into sulphate, while the zinc sulphide remains practically unaffected If the product is then washed in hot strong brine, the lead sulphate is dissolved, and can then be separated from the undissolved zinc sulphide by filtration, etc. By cooling the hot brine, the lead sulphate is precipitated—except for the amount that cold brine will keep in solution—and the brine can then be reheated and used again. The details, of course, vary for different ores and there are alternative methods for handling the sulphur dioxide, sulphuretted hydrogen or free sulphur liberated during the treatment."

Problems in Electric-Furnace Smelting*

A Description of Investigations to Determine the Best Arrangement of Electrodes, Leads, Etc., of the Ultimate Relation Between Electrical and Metallurgical Phenomena Within the Furnace and of How to Operate a Furnace to Obtain the Highest Output

By F. HOLMGREN

Introduction by Translator

IT IS well known that the earliest blast furnaces were built in Sweden, and so also Sweden first successfully solved the problem of the use of electric furnaces for the production of pig iron directly from the ore. The reason for this is naturally to be found in the facts that Sweden has an abundant supply of very high-grade iron ore and cheap water power, which are essential for the commercial success of the process. Coal is very expensive in Sweden and with a small exception the entire consumption has to be imported. It is for that reason that it has been more profitable in the past to export millions of tons of ore annually; but it is hoped that with the successful solution of the electric furnace and its more general adoption, a large part of this ore may be reduced at home and used in expanding the steel mill industry of the country.

Besides iron ore and limestone, charcoal has in the past been the other necessary raw material, but it is stated that recent improvements in the construction of these furnaces make them equally suitable for the use of coke in place of charcoal. The scarcity of charcoal in the United States is undoubtedly one of the reasons why this type of furnace has not been more extensively tried out in this country, and if it is true that coke is a satisfactory reducing agent, we shall undoubtedly soon find many of these furnaces installed here.

There are at present thirteen of these furnaces in operation in Sweden, and four under construction of capacities up to 6,000 kw. each. There are also seven under construction in other countries, several of which are said to be for using coke as a reducing agent. The productive capacity varies from three to four tons of pig iron per kw.-yr., depending on the quality of the iron produced.

The following article is of considerable interest in that it deals with a number of investigations which were made on existing furnaces in order to determine the best arrangement of electrodes, leads, etc. In one case, for instance, the power consumption was reduced from 474 kw. to 282.5 kw., or 40 per cent, simply by changing the connections from transformer leads to electrodes; moreover, the power factor was raised from 0.7 to 0.91. It also explains the intimate relation between the electrical and metallurgical phenomena within the furnace, and how the operation of the furnace can be controlled for the highest output by a close observation of the electrical measuring instruments.

Investigations of Furnace Operation

The Helfenstein Furnace.—The investigations were begun with furnace 3 at Domnarfvet Steel Works. This furnace was built by Helfenstein and showed the poorest results, both as far as operation and power consumption per ton pig iron were concerned. The heat had a tendency to rise higher and higher in the stack and the heat losses were considerable. The electrode potential could not be brought up to the desired value, and it was thought that this was due to too short a path of the current. To overcome this, water-cooled bridges were provided between the electrodes in the furnace dome in order to force the current to pass through the bath. The energy losses in the leads between the transformers and the electrodes were measured by the three-voltmeter method and found to be not less than 17.5 per cent of the total capacity.

The above changes and numerous other tests and trials failed to improve the results, and similar investigations were started at the Soderfors Steel Works.

The Soderfors Furnace.—This furnace, which is of the "electrometal" type, had shown much better operating results than the Helfenstein furnace at Domnarfvet, but on the other hand the power factor was lower than for furnace 2 at Domnarfvet, which also was of the electrometal type. Electrically, the principal difference in the arrangement was that with the former the transformers were installed in a separate room about six meters from the center of the furnace, while for the latter they were placed immediately near the furnace wall. The frequency in the former case was 50 and in the latter 60.

In these tests complete voltage diagrams were drawn by means of the three-voltmeter method, whereby the losses and the inductive voltage drop in the different leads could be determined. All the measuring instruments had before always been connected to the transformer terminals or near these, whereby the effect of the leads from the transformers to the electrodes was included. This, of course, was not the correct method, as what is most valuable for a study of the furnace operation is a knowledge of the current and voltage at the electrodes proper.

In the first test of the Soderfors furnace a relatively symmetrical voltage diagram, Fig. 1, was obtained, and the losses amounted to 474 kw., or to about 16 per cent of the total capacity. In the diagram the losses F are shown as the projection of the voltage drop on the current I. Points T represent the transformer terminals and E the electrodes. The diagram shows, however, that the furnace was not symmetrically connected, so that the six electrodes will not follow one another in the same sequence in the voltage diagram as in reality.

With currents up to 20,000 amp. or more, which are common with these furnaces, the magnetic fields set up about the conductors become very strong if not compensated for. In this installation, which is three-phase at 50 cycles, the direction of current will change 100 times for each second and the three currents will be

*Abstracted and translated from the *Transactions* of the Swedish Iron Institute by E. A. Lof.

displaced with respect to each other one-third period. If now the same current is carried forth and back through two adjacent conductors (one going and one return conductor), then the electromagnetic fields set up by the two conductors will be equal but opposite. The conductors will therefore compensate each other, and there will, practically speaking, be no electromagnetic field. If, however, a conductor is placed adjacent to

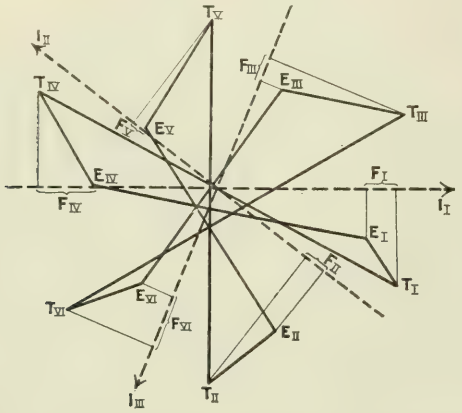

FIG. 1. CURRENT AND VOLTAGE RELATIONS IN SODERFORS FURNACE

another, and one carries a different current, or current of a different phase than the other, then the electromagnetic field will be greater or less, depending on how the fields set up by the two currents will combine vectorially.

In the diagram, Fig. 2, are shown the results from the first test of the Soderfors furnace. The strength and phase-displacements of the currents are drawn to scale, and represent also the electromagnetic fields set up. Besides this, there is shown in the smaller diagram the leads around the furnace and the direction of the currents therein. The directions of the arrows thus correspond to one another in the two diagrams. We see therefore in the smaller diagram how the arrows of the conductors between electrodes *I* and *II* have the same direction, while between the other electrodes this is not the case. The resultant of the two currents, therefore, gives a field proportional to $R_{1,2}$. The two others will, on the other hand, be respectively $R_{5,6}$ and $R_{3,4}$. The electromagnetic fields which thus surround the conductors will be increased by adjacent iron structures which will lower the magnetic reluctance. Such structures are the furnace casing, iron pillars, etc. In these iron parts eddy currents are now in turn set up, which are converted into heat. The less compensated the leads, the greater will be the iron losses thus created. The fields will besides set up electromotive forces in the conductors themselves, which may cause a drop and even a rise in the voltage.

Losses Reduced by Interchange Electrode Leads

The terminals of the transformers for electrodes *III* and *IV* were then changed so that the direction of the current in the circuit was reversed. The result was measured and is shown in Fig. 3. At a first glance it would seem as if the first connection would have been the correct one on account of the symmetrical and otherwise clear vector relations. The unsymmetrical diagram depends, however, on inherent conditions in the furnace which will be dealt with later.

From the diagram it follows that certain losses ($F_{2,\ 4,\ 6}$) have become negative, that is, that a power increase has taken place instead of a loss. This is readily explained. On account of the above-mentioned mutual induction a certain amount of power has been transformed from one lead to the other, in that the former has acted as the primary winding in a transformer and the latter conductor as the secondary. The adjacent iron structure has served as the necessary "transformer" core. If we consider the fields which could have been formed around the conductors, we find (Fig. 4) that in the latter case these have become much smaller, which must result in lower additional losses. This proved to be the case, as the losses went down to about 375 kw.

The low power factor caused by the relatively large inductive voltage drops (represented in Fig. 1 by the lines at right angles to the currents) could not, as expected, be improved by this reconnection, and it was then suggested that the transformers should be connected to adjacent electrodes instead of to opposite ones as had been done before. Investigations involving the inherent electrical conditions of the furnace were made and it was found that this suggestion was practicable.

If we assume that an electrode of circular cross-section with radius r cm. is lowered to a depth of h cm. in a conducting homogeneous mass with a specific conductivity c, then the resistance which the current has

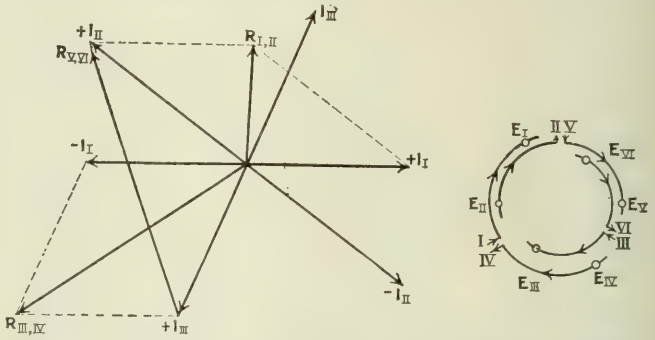

FIG. 2. MAGNETIC FIELDS AND ELECTRODE CONNECTIONS FOR FIRST TEST

to overcome in its travel from the electrode to a concentric cylinder area with the radius R cm.:

$$M = r\int \frac{Rdx}{x} \cdot \frac{c}{2\pi h} = \frac{c}{2\pi h} \log_e \frac{R}{r} \text{ ohms.}$$

From this we get the voltage

$$E = \frac{Ic}{2\pi h} \log_e \frac{R}{r}.$$

The energy production per unit volume will therefore be

$$\frac{dU}{dx} = \frac{1}{x^2} \cdot I^2 \frac{c}{2\pi h} - \text{const.} \frac{I^2}{x^2}$$

and will therefore drop rapidly the farther the distance from the electrode.

The zone nearest the electrodes may be considered as consisting of a number of parallel arcs, where the resistance and the voltage drop presumably follow other laws. Oscillograph tests of the applied current and voltage have shown that these have a practically sinusoidal wave shape. Whether this was due to impossibility of connecting the oscillograph sufficiently near the arc itself, to the heat capacity of the arcs, or to other causes, could not be determined. This resistance may depend, however, upon the current density, the

temperature, the composition of the charge, and the distance between the electrode and the bath. Besides this, the gas currents and finally the electromagnetic field may have their influence.

Distinction Between Working Resistance and Conductor Resistance

It is in this zone presumably the principal direct energy generation takes place. Outside of the zone the above laws may hold, excepting that the resistance will increase with a falling temperature. The energy generation drops therefore less rapidly than the formula would indicate. In the former zone we thus have the real "working resistance" and in the latter the "conductor resistance" to the next working zone.

There is no doubt that the "working resistance" preponderates, but it is not quite clear what rôle the "conductor resistance" to the next working zone plays.

This electrical condition with two such zones is known by the term "free" electrodes, and represents a normal operating condition. If no arc zone exists, we say that the electrodes are "frozen." This occurs when the potential required for maintaining the arc cannot for

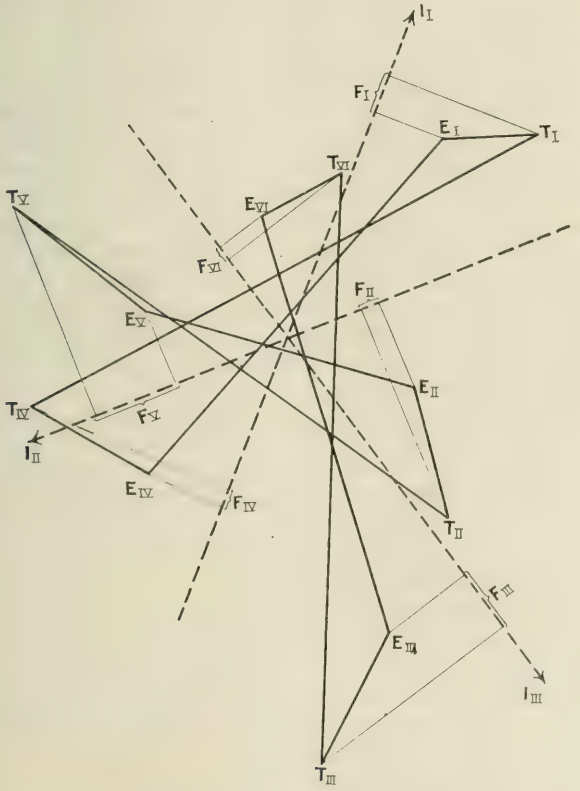

FIG. 3. DIAGRAM WITH LEADS TO III AND IV (FIG. 2) REVERSED

some reason or other be produced. The condition appears as a lowered "working resistance" (consequently increasing current), rising temperature in this part of the hearth and reduced production.

Regarding the effect which the "conductor resistance" in the mass itself may have and its effect on the heat development in the furnace, it may be of interest to determine how the different currents proceed through the crucible.

Fig. 5 represents the progress of the currents within the furnace when complete symmetry exists, that is, when the currents in the three phases are equal, the furnace connections symmetrical and non-inductive and when the currents enter and leave the crucible through opposite electrodes. We find that the currents entering will divide according to the parallelogram law into components such that the current between either of the electrodes will be equal to the current entering.

In connection with the first investigations of the

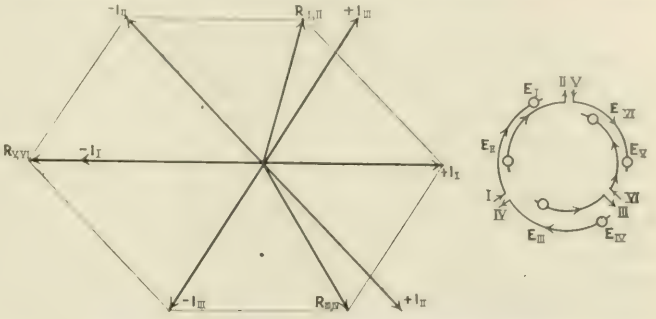

FIG. 4. REDUCED MAGNETIC FIELDS WITH LEADS TO III AND IV REVERSED

Soderfors furnace it was found after the shut-down that the lining was more corroded between certain electrodes than others and it may be assumed that the greatest effect in the mass took place there. It is, however, difficult to say whether this really had anything to do with the two conditions referred to or was just a circumstance.

It has not been possible to determine the effects of the unsymmetrical condition and the different currents passing through the charge, but from the voltage diagrams it is fairly evident that even the "conductor resistance" of the mass is a factor which must not be lost sight of in considering the heat distribution in the furnace. The diagrams thus show that there is far from a common neutral point, for which reason it must be assumed that work has also been done by the currents in the mass. Cold spots between certain electrodes were thus found in the Soderfors furnace. There is some uncertainty as to the magnitude of the work done in the mass itself between the electrodes and its effect on the thermal procedure within the furnace.

Best Results by Connecting Transformer Leads to Adjacent Electrodes

Regardless of how the effects are distributed on the arc zones and in the mass itself, we see therefore that the current paths will not be any longer if the transformer terminals are connected to two opposite electrodes than if they are connected to two adjacent electrodes. It was therefore decided to change the connections so that each phase was connected to two adjacent electrodes. The result was, as expected, a considerable reduction of the losses in the conductors, which went down from 375 to 282.5 kw. with the same operating condition of the furnace. The power factor, furthermore, was improved to such an extent that from a power consumption of 4,420 kva. now only 3,395 were required, or a saving of not less than 23 per cent in kva., resulting only from the rearrangement of the leads. The power factor improved from 0.7 to an average of 0.91.

Electrometal Furnace 4 at Domnarfvet.—This furnace showed, to begin with, the same trouble as the Soderfors furnace before the leads were rearranged. Furnace 4 has eight electrodes arranged with a double "Scott" connection, and is therefore equivalent to a doubling of the set at Trollhattan.

The power factor was found to be low, hangings occurred and the operation was for this reason uneven at the different electrodes. The leads were arranged as for the Soderfors furnace, that is, the terminals of the respective transformers were connected to diametrically opposite electrodes. Very thorough investigations were made on the furnace.

In Fig. 6 is shown a complete vector diagram of the connections in which the magnitude and direction of the currents and voltages are marked. As there is no real neutral within the furnace, that shown in the diagram will be regarded as fictitious. The great difference, both in magnitude and direction, between the voltages at the transformer terminals and at the electrodes, is at once apparent. For electrode 6, for example, the voltage between the corresponding transformer terminal and neutral is about 41 v., while between the electrode itself and the neutral it was found to be only about 15 v. The phase-displacement with reference to the fictitious neutral was in the former case only about 0.16 and in the latter about 0.8. It is therefore apparent what little help we have from instruments connected to the transformer terminals, as a guide for operating the furnace.

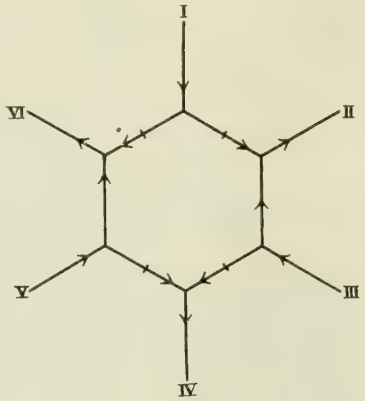

FIG. 5. CURRENTS IN THE FURNACE FOR BALANCED CONDITION

Analysis of Losses

From this diagram it was now possible to approximately determine the distribution of the losses in the different parts of the conductors, and the values so obtained have been combined in Fig. 7. This shows still more clearly the faulty interpretation one may get from the instruments as regards the load on the different electrodes. So, for example, the wattmeter indicated a load of 1,020 kw. for electrodes 4 and 8, while in reality the electrodes received only 637 kw. Still more peculiar is the result at electrodes 2-6, where the meter indicated 744 kw., while in reality the electrodes received not less than 1,019 kw. This big difference can be explained by an insufficient interlacing of the conductors and the fields thus set up, besides the transformation of work from one conductor to the other.

At the test in question a total of 3,942 kw. was applied, of which only 3,392 kw. were useful in the furnace, leaving a 603-kw. loss in the 80 m. leads between the transformers and the furnace. These were segregated as follows:

Losses in the contact terminals:	kw.
At the electrodes	122.2
In the leads themselves	164.2
In surrounding iron structures	316.6
Total	603.0

From one set of conductors to another there was transformed no less than 544.4 kw. With a rearrangement of the leads to correspond to that at Soderfors, it was estimated that the losses could be cut in two. Regarding the furnace leads, the following rules can therefore be laid down:

The low tension conductors should be so arranged that adjacent electrodes are connected to two opposite transformer terminals, and that these + and — circuits are carried the shortest distance and in such an interleaved manner that the magnetic fields will be neutralized.

The measurements give a clear picture of the electrical properties up to the electrodes and teach us the best method in which to arrange the leads. Inside the furnace we know that the resistance can be divided in a "working resistance" in which the principal energy is developed, and a "conductor resistance" between the electrodes. It has been shown how the currents pass through this conductor resistance, but it has not as yet been possible to determine the relative magnitude of the two resistances, which undoubtedly has an intimate relation to the operation and the furnace temperature.

It can safely be assumed that unequal heat supply also was the cause of the irregular operation which was noticed both in furnace 4 at Domnarfvet as well as in the Soderfors furnace before the connections were changed, while the performance of furnace 2 at Domnerfvet was decidedly better from the beginning. As seen from Fig. 8, the leads did not here cause the same disturbing effect on the instrument readings. Regardless of how the furnace leads are arranged, the instruments must always be connected as close to the electrodes as the heat radiation from the furnace will permit. With a perfect arrangement of the leads, then, this is of course not so important, as confirmed by Fig. 9, which represents a voltage diagram of the Soderfors furnace after the leads had been changed. This diagram should therefore be compared with diagrams Figs. 1 and 3, but above all with Fig. 6.

From the preceding there is good reason to believe that there exists a certain reciprocal action between the electrical and metallurgical phenomena of utmost importance inside the furnace.

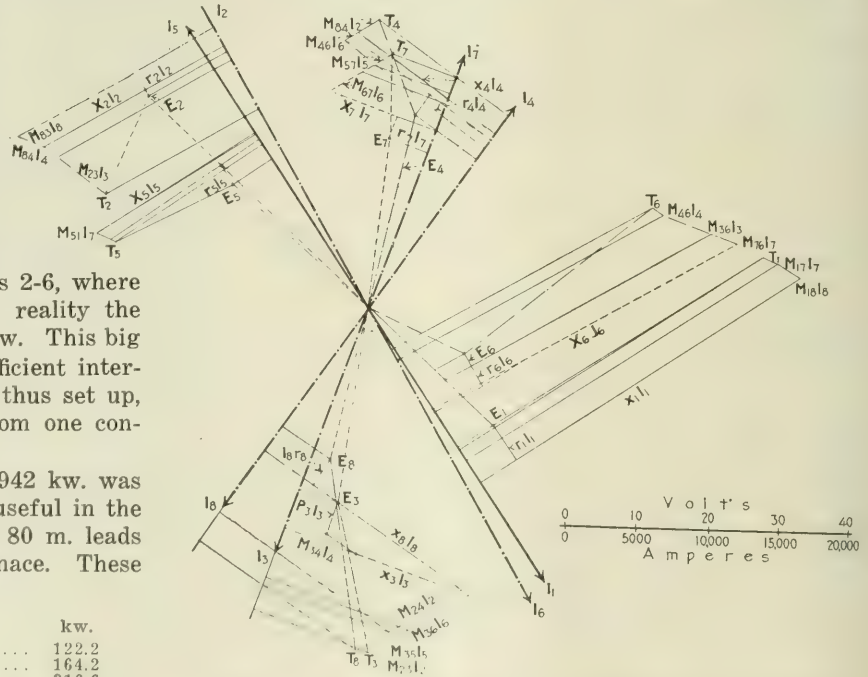

FIG. 6. COMPLETE VECTOR DIAGRAM FOR FURNACE 4 AT DOMNARFVET

Earlier investigators have already dealt with the equilibrium of electric-furnace operation in that with a surplus of coal the operation will readily become "hot," meaning that the furnace temperature would be above normal, while with a surplus of ore it will become "cold," meaning that the furnace temperature would be below normal. The former condition is characterized by a tendency of the current to rise, that is, the resistance in the furnace drops and the temperature rises with reduced operation. Referring back to the previously mentioned division of the resistance inside the furnace, we find in the first place that the "working resistance" drops, which undoubtedly depends on the reduced operation.

It may be possible that this takes place in the following manner in that in the active arc zone the reduced iron drops down into the bath below the electrodes, and the carbon monoxide escapes the easiest way along the electrodes up to the stack, whereby the section nearest these will be exposed to an unusually severe heat.

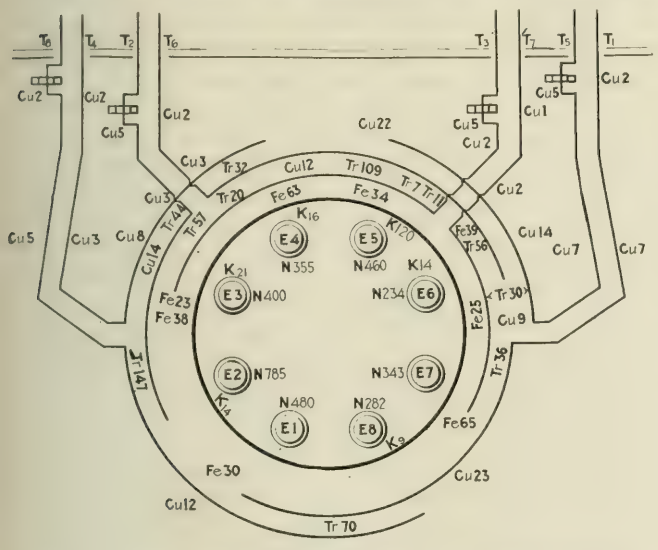

FIG. 7. LOAD DISTRIBUTION TEST OF DOMNARFVET FURNACE 4

The gas blast will cool the mass and the arch between the electrodes, whereby at least the upper part of the mass between the electrodes will have a relatively low temperature and a correspondingly higher resistance.

If now there is a reduction in the operation on account of a surplus of carbon, then the real smelting zone, which therefore practically contains iron drops and rising carbon monoxide, will be thinner and thinner, and the working resistance will drop. The surrounding zone, which practically consists of conducting carbon, will be forced more and more toward the electrode, until if finally sticks to the same, and the "working resistance" ceases more or less to exist. The resistance between the electrode and the mass is thus exceedingly small and the current rises considerably. As the reaction $FeO + C = Fe + CO$ is strongly endothermic, and as any cold charge is prevented from descending into the bath, the reduced operation will always mean an increased heat supply to the mass surrounding the electrode, which also in turn lowers the resistance in the mass between the electrodes. If in the charge, when it enters the hearth, there is a certain surplus of carbon in proportion to the available oxygen for formation of CO, then there is, of course, no possibility for this to oxidize, as, contrary to ordinary blast furnaces, the mass is not passed through by any gas with an oxygen surplus. An accumulation of carbon will then take place which will more and more prevent the charge from descending and a reduced operation will result. Such carbon accumulations are especially apt to take place when coke is used on account of its compact nature and its tendency to graphitize.

The "cold" operation, on the other hand, is characterized by the fact that with a rich easy reducible ore there will be a too large arc zone around the electrode with accompanying high "working resistance." On account of the increased operating condition, the surrounding mass will not be sufficiently supplied with heat, but will solidify. The arcs between the electrode and the mass will finally go out and the operation will stop.

Unbalanced Operation Between Electrodes

As has been pointed out above, the heat supply has often proved to be very irregular at the different electrodes. On the other hand, it seems to be true that the arc zone, which is desirable for a successful and regular operation of the furnace, has a certain relation to the operating conditions of the electrode in question. As soon as the charge around the electrode reaches an unsuitable composition (surplus of coal or ore) it has been found that the operating condition becomes bad, either due to electrical heat supply with accompanying disturbance of the electrical phenomena (during "hot" operation) or because the electrical phenomena have been disturbed with an accompanying checking of the electrical heat supply (during "cold" operation). In the former case an increased ore supply is resorted to and in the latter a reduced supply.

That the heat in electric furnaces is very unevenly distributed cannot be disputed, and that an uneven energy supply through the electrodes will still further increase this condition is self-evident. The result of this has also often shown itself during tappings, in that the iron then often shows a changing temperature.

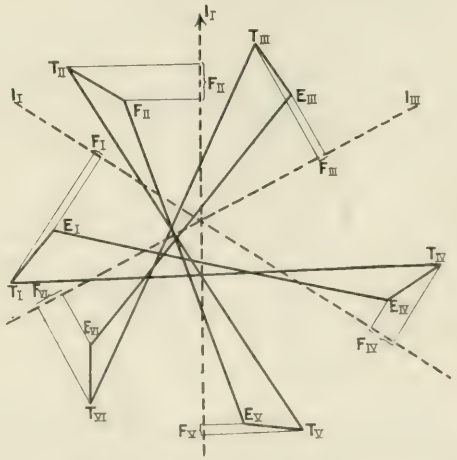

FIG. 8. TEST OF FURNACE 2 AT DOMNARFVET

It even sometimes happens that at tappings iron and slag will be poured in alternating successions.

It shows therefore that there has been an irregular metallurgical condition at the different electrodes, depending partly on the uneven energy supply and partly on a different composition of the charge at the different electrodes. At one electrode the furnace may thus show typically "hot" operation with a low effect, while the operation at the other electrode may be entirely

normal. The uneven successive tapping of iron and slag can naturally also be due to the fact that under each electrode there has been formed an individual iron bath with accompanying slag cover, which confirms the unequal heat distribution within the furnace.

Electrodes Should Be Controlled Individually

It seems therefore that the crucible of an electric furnace can be considered as consisting of a number of furnaces equal to the number of electrodes. When the operation of an electrode tends to get "hot" it should therefore be possible to prevent this by cutting off the current from this electrode for such a length of time that the surplus of carbon may be removed in some manner. As an increased ore supply through the stack affects all the electrodes, it would seem that in order to obtain a steady operation of the furnace the electrodes should be controlled individually. With "hot" operation, ore should therefore be supplied through special holes in the dome to the respective electrodes if such holes will not unduly weaken the furnace construction.

The uneven distribution of coal and ore in the charge, which is liable to cause a "hot" operation, should therefore be avoided by a careful mixing before the charging. If ore and coal are supplied to the furnace in the ordinary way in form of alternate layers, it is possible that the profile of the stack may influence the charge at the electrodes. If we follow the layers down through the stack, we find that the sinking will be more rapid in the center of the stack on account of the friction against the walls, Fig. 10. It is therefore possible that the occasional surplus of coal is due to the fact that a layer of coal, or a part thereof, during its progress through the bosh, will take up a position parallel to the

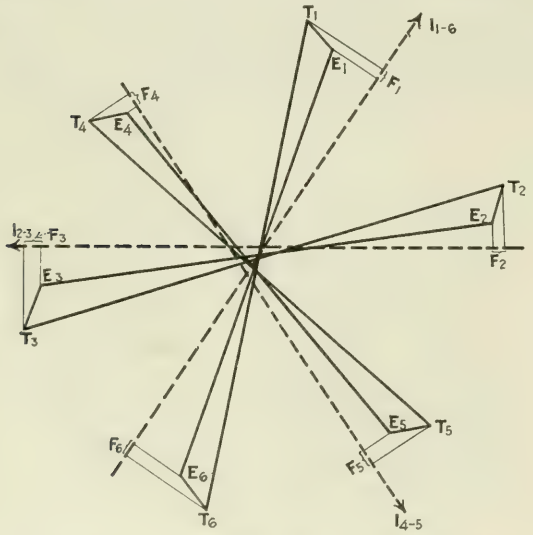

FIG. 9. VOLTAGE DIAGRAM FOR FURNACE WITH CORRECT ARRANGEMENT OF LEADS

electrodes, and finally surround the same in the form of a mantle and thus prevent the operation with a resulting over-heating.

Another kind of "hot" run is also possible, namely, when the electrode is unable to burn itself free and form an arc, regardless of the fact that the charge does not contain any local or general surplus of carbon. This may depend on the special nature of the electric-furnace process, in that the furnace can be supplied with only a sufficient quantity of electrical energy required by the process on the supposition that this is produced in arcs. By simply conducting the circuit through the charge it is not possible to produce the required energy and heat for the furnace, on account of the limited low value of the resistances. Why a reaction corresponding to this energy does not take place in the mass so heated and thus cause reduced operation, is difficult to explain. Instead we obtain a surplus of heat in the furnace. It may possibly be caused by the fact that the smelting process ceases and that therefore the reduced material is not removed as rapidly as necessary.

Causes of Operation With "Frozen" Electrodes

This corresponds to what was found with the Helfenstein furnace. A low electrode voltage could not be used on account of the inside resistance of the furnace. The operating capacity was very small and the operation very "hot," the heat rising further and further in the bosh and stack. As soon as a higher voltage could occasionally be noticed at any of the electrodes an increased capacity was also observed. The electrode has then very likely burnt itself free, while the Helfenstein furnace thus "normally" ran with frozen electrodes. The reason for this might have been that the contact surface between the electrode and the mass, due to the furnace construction, was too great, so that the energy required for burning the electrode free was greater than could be produced with the arrangements of the leads, etc.

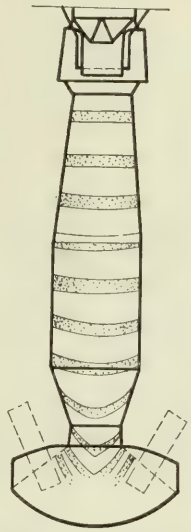

FIG. 10. PROGRESS OF CHARGE THROUGH THE FURNACE

"Hot" operation due to the same cause was also noticed in the Soderfors furnace before its reconstruction. The great distance to the bottom of the furnace made it often necessary, especially with hangings, to push the electrode far down in order to get any current to pass. When then the charge fell, the reaction surface became too great and the electrode was unable to burn itself free. On account of the great free length of the electrodes within the crucible and their slope with respect to the "falling-down" angle of the mass, they were often broken. The remaining stump was then quickly pushed down to prevent burning of the roof, and contact with the broken-off part was established, with the result that the reaction surface became still greater and a burning-free was impossible. Since the height of the crucible has been considerably reduced, any "hot" runs from this cause have not been observed.

Reducing Losses by Rebuilding the Crucible

As a result of the rebuilding of the crucible, it may be noted that with a suitable electrode surface in the mass, the current became relatively low, which, of course, was of greatest importance as far as the secondary transformer windings and the low-tension leads were concerned. It was furthermore possible to keep the voltage high without unduly overheating and damage to the furnace lining. The low current had an especially favorable effect on the losses in the conductors, as these were reduced to only about 180 kw. from 282.5. The inside resistance of the furnace was increased from 1,250 microhns per electrode to not less than 2,700 michrons, and it is, of course, desirable to keep this

resistance as high as possible. The upper limitation is the risk of "cold" operation with a rich charge and irregular operation on the whole due to the tendency of the arcs to go out, besides the silica reduction.

From the above it is apparent that it is very important to use electrical measuring instruments for obtaining a knowledge of the metallurgical progress inside the furnace. The operation is closely related to the load for the same charge, and it is necessary to gain a knowledge of the resistance which is obtained in the furnace for different compositions of the charge, in order to determine on the best operating method therefor. With a charge rich in ore and thus low resistance, for example, it is not permissible to wait with the lowering of the electrode until the same voltage is reached as with a poorer charge with a relatively high resistance.

Points of Consideration in Planning New Electric Furnaces

Frequency. Some of the furnaces with the original arrangement of the connections, that is, with the transformers connected to opposite electrodes, operate with 25 cycle power and a good power factor. There are also several furnaces with the new arrangement of connecting the transformer to adjacent electrodes in operation on 50 cycle power, with good power factor results and low losses in the conductors. If the leads, therefore, are correctly arranged it may be stated that electrical furnaces can be satisfactorily operated with any of the standard frequencies now in use.

Electrodes. There are two ways in which the capacity and thus the production of a furnace may be increased. One is by increasing the electrode diameter with the number of electrodes remaining the same, and the other by increasing the number of electrodes, keeping the diameter the same. Both these arrangements necessitate an increase of the current supply. An increase of the voltage is, however, not permissible on account of the irregular operations which would result therefrom and the effect which the voltage has on the furnace process in reducing the silica. Of the two first named arrangements, an increase in the size of the electrode will surely result in an increased operation on account of the larger smelting zone which is thus obtained, but the difficulties with the current supply will also grow in that the "useful" area of the electrodes, due to the skin-effect, will not increase in the same proportion to the actual area. Besides this there will be increased difficulties in connection with the leads for carrying the large currents. It seems, therefore, as if more can be gained by the second alternative, that is, by increasing the number of the electrodes. At present there are furnaces with 4, 6 and 8 electrodes, and from the electrical point of view there is no reason why the number cannot be increased to 9. The "neutral" column of the charge is, however, likely to be larger and larger, and it may be questioned whether it would not be advisable from an operating standpoint to raise the bottom of the crucible in the center when the diameter has reached a certain dimension, provided that this would not cause an increased pressure of the charge against the electrodes.

Electrode Terminals. This is generally one of the weak points in electric-furnace installations, and every effort should be made to improve the same. A good contact is essential, as about 30 to 40 per cent of the losses from the transformers to the electrodes are to be found here. Arrangements should also be made to facilitate a quick change of electrodes and an easy raising or lowering.

Leads. As has already been explained, the tests and investigations have shown conclusively that the leads must be arranged in a manner which will reduce the resultant electromagnetic fields to a minimum. Conductors which carry the same current but in opposite direction should be placed together as close as possible. This led to the suggestion of connecting adjacent electrodes to the same transformer phase, whereby a much better power factor is obtained and also shorter connections and lower losses therein. The form of the conductors is also of great importance with alternating currents when large currents have to be handled, on account of the influence which the electromagnetic field around the conductor has on the current distribution within the conductor, reducing the useful area. It has also been proved that with uncompensated conductors very little is gained regarding the current distribution therein whether these consist of multiple or solid bars. Better radiation is, of course, obtained and therefore a lower direct current resistance, but the current within the conductors will nevertheless be distributed as if the conductor had been solid. Where the conductor run is uncompensated, that is, where it is impossible to interleave + and — bars, it is advisable to arrange the conductor in the form of a pipe, two half pipes or eventually as four bars arranged to form a square. At 50 cycles it will be possible in this manner to bring down the losses to less than one-half of that with parallel bars. In other words, only one-half the amount of copper need be used in these portions of the leads.

As far as the compensated part of the leads is concerned, much has been done to reduce the surrounding electromagnetic fields by interleaving the + and — bars. For the same area the resistance will also be lower if the thickness of the two outside bars is made only one-half of the inside ones. Where the individual bars are of different lengths the longest ones should be placed outside so as to obtain as low field as possible around the same. Each bar should preferably be connected to an individual transformer winding, and in such case the forward and the return conductors should be bunched and interleaved. They should also be arranged so that the voltage drop in the conductors to the individual transformer windings will be as nearly alike as possible, in order to assure an equal distribution of the load among the different windings. When pipes are used for the leads the amount of copper can be reduced by water cooling. The losses will, however, be higher. Such water-cooled pipe conductors are often used in the leads nearest the electrodes where the heat from the furnace is excessive.

Electrical Arrangement. From what has been said in the above it is evident that the shorter the leads the better will the operation be from the electrical point of view. This was fully demonstrated in furnace 2 at Domnarfvet, where the transformers were placed immediately adjacent to the furnace, and where the operation was the best from the beginning. From the general operating standpoint, however, this arrangement has many disadvantages, in that it takes away much of the space nearest the furnace which is essential for the operation otherwise, and besides this the transformers are directly exposed to the heat from the furnace. This

arrangement has therefore not been followed in the later installations, where the transformers have been placed in a common room separated from the rest of the installation. This transformer room has in different installations been located at different elevations with respect to the control platform, but the leads have generally been carried along the ceiling above this platform and from there down to the electrodes. It would seem advisable, however, to install the transformers at such a height that their terminals would be at the same elevation as the electrode terminals; in other words, the leads should, if possible, be installed in a single horizontal plane.

Furnace Operation From the Electrical Point of View

In the preceding it has often been pointed out that in the electric-furnace process the metallurgical and electrical phenomena have an intimate relation to one another, and from this it follows that the operation must be with this in view.

The problem is to produce the greatest quantity which the limitations of the installation will permit, and this with due consideration of the quality of the product. When such a furnace can produce up to 10,000 tons of pig iron per year and possibly more, the importance of keeping the operation uniform and at near maximum is obvious. All interruptions, etc., should be localized to include as small a part of the installation as possible.

On account of the connections to the transformers, there has so far always been a mutual electrical relation between two electrodes. But inasmuch as the operation has been found to be somewhat independent at the different electrodes, the question arises whether it would not be advisable to make an arrangement whereby each electrode could really be independent of the other. This could most easily be done by means of a bottom electrode connected to the transformer neutral. Whether this would meet with any practical difficulties, however, must first be investigated. Another advantage of this would be that in case of repairs or when changing electrodes, only one electrode need be disconnected. With a surplus of coal at one electrode the current could be shut off temporarily from this electrode to prevent "hot" operation. A closer and more frequent regulation of the electrodes would then also be possible, thus permitting the highest voltage to be maintained more uniformly.

Electrical Instruments as Guides to the Operator

The electrical instruments serve as a good guide to the operator provided they are connected so that the leads to the furnace have no disturbing influence. Individual measurements at the different electrodes are preferable, and for this reason the instruments should be connected either to the bottom electrode if there is one, or otherwise to some suitable conducting point in the bottom of the furnace. Besides a voltmeter which should be able to be connected between the neutral and the respective electrodes, there should always be a wattmeter for each pair of electrodes, the potential coil of which can be interchanged to different electrodes. By thus carefully following the size of the "working resistance," it would at least be possible to discover in time when there is a tendency for "hot" or "cold" operation and thus make it possible to take the necessary precautions against it. A knowledge of the load on each individual electrode should also give an indication of the limitations as far as the furnace lining is concerned, and it would be highly desirable to have pyrometers installed in the roof near the electrodes if this could be done from a practical point of view. It would then be easy to determine when the electrode should be lowered.

Conclusion

1. The low-voltage leads are of utmost importance as far as the losses and power factor are concerned, and their arrangement should be carefully planned in new installations.

2. The electrical measuring instruments should be arranged so that they will really indicate the electrical conditions at the electrodes.

3. There is an intimate connection between the electrical and metallurgical phenomena at the different electrodes, and an individual control of the electrodes is desirable. It seems that the electrical measurements should be a good guide in determining the metallurgical progress, and for this reason we should endeavor to obtain a deeper knowledge of the relation between the electrical measurements and the metallurgical phenomena. An intimate collaboration between the metallurgist and the electrical engineer is essential in this study of the same, as in the study of the physical character of the arc zone.

Crucible or Electric Steel for High-Speed Tool Steel?

According to the writer of an article in *The Edgar Allen News*, entitled "Crucible or Electric Steel?" electric steel, owing to its purity and comparative cheapness, is admirably suited for many purposes such as constructional parts of motor cars and aëroplanes, miners' drills, blacksmiths' tools, etc., but when it is used solely for producing steel of the highest quality, such as high-speed tool steel, the final word has yet to be said which would place electrical steel in the same class with that of the tried and proved product of the crucible.

Many plausible reasons are given by electric steelmakers for the alleged superiority of high-speed steel made by their process. They claim, for instance, that, as each cast of electric steel is a large one, greater uniformity can be guaranteed than with the crucible process, in which twenty-four crucibles full of steel may be required to make the same weight of steel. But the crucible steelmaker may justly reply that high-speed steel is a very complex alloy; that each constituent, carbon, tungsten, vanadium, chrome, manganese, etc., must be present in exactly the right proportion, or the steel will not be up to the mark; and that in this respect the crucible process is vastly more under control than the electric. Each ingredient being carefully weighed and the crucible sealed, only an accident could alter the composition, and should an ingot be altered in this way it would be readily detected.

Moreover, while one wrong ingot out of twenty-four would not worry the crucible steelmaker, a whole cast of electric steel which went wrong would be a serious business for the electrical maker. If it were only slightly wrong, there would be a great temptation to finish the steel and risk the errors being discovered by the user.

Exaggerated claims of advantages for electric steel should, therefore, according to the writer, not be taken too seriously.

Cooling Liquids in Spray Systems and Cooling Towers

A Description of the Principles Involved in Cooling Liquids—Factors Governing the Capacity of the Cooling System Employed—Data Obtained in Testing the Ceco Spray System—Possible Application of Spray Cooling for Crystallizing Work in Chemical Industries

BY EDWIN M. BAKER

IN MANY industries it is frequently necessary to cool hot liquids, either clear solutions or solutions containing suspended solids. Also where a large supply of cooling water for condensers and similar usage is not available, it has become practice to cool the condenser water by some form of spray system or cooling tower, so as to permit using the cooling water over and over again.

The various spray systems and cooling towers all work on the same principle: i.e., they aim to bring the water to be cooled in contact with air, and to effect a cooling of the water (1) by exchange of sensible heat, the water being cooled and the air heated, and (2) by saturating the air with water vapor to cause evaporation of part of the water, thus removing some heat as latent heat. In general, it may be said that the bulk of the cooling is due to the latter effect, but the exact distribution of the cooling may be found only if the entering and exit temperatures of the air and water, and the relative humidity or saturation of the entering and exit air, are known. In any system, if there be no radiation of heat, or if this is so small that it may be neglected, it is evident that the total heat entering in the air and water must equal the total heat leaving in the air and water.

In the following discussion let

t_1 = temperature in deg. F. of entering air.
t_2 = temperature in deg. F. of exit air.
t_3 = temperature in deg. F. of entering water.
t_4 = temperature in deg. F. of exit water.
L_1 = latent heat of steam at the temperature t_1.
L_2 = latent heat of steam at the temperature t_2.
a = lb. of water vapor per lb. dry air carried by entering air, as obtained from wet and dry bulb readings.
b = lb. of water vapor per lb. dry air carried by exit air, as obtained from wet and dry bulb readings.
c = mean specific heat of dry air at constant pressure, in B.t.u. per lb. air per deg. F., taken as 0.2373.
W = lb. dry air entering per minute.
Q = lb. hot water entering per minute.
V = lb. cooled water leaving per minute.

The total heat entering will be the sum of the heat in the water and in the air. The heat above 0 deg. F. carried by the air will be composed of three parts: first, the sensible heat of the dry air, equal to Wt_1c; second, the sensible heat in the water vapor carried by W lb. dry air $= Wat_1$, and third, the latent heat in the water vapor carried by W lb. of dry air $= WaL_1$. The heat carried by the entering water will be sensible heat only, and will equal Qt_3. Therefore the total heat in B.t.u. above 0 deg. F. entering equals $Qt_3 + Wt_1c + Wat_1 + WaL_1$. The heat leaving is likewise, first, sensible heat in dry air $= Wct_2$, second, sensible heat in the water vapor carried by W lb. of dry air $= Wbt_2$, and third, latent heat in water vapor carried by W lb. of dry air $= WbL_2$. The heat leaving by the exit water is Vt_4. Therefore the total heat leaving is $Wct_2 + Wbt_2 + WbL_2 + Vt_4$. Equating these two, we get $Qt_3 + Wt_1c + Wat_1 + WaL_1 = Vt_4 + Wct_2 + Wbt_2 + WbL_2$.

The amount of water entering as liquid equals the amount leaving as liquid plus the amount evaporated, or $Q = V + (b - a)W$. Substituting this value for Q and collecting terms, we get

$$W = \frac{V(t_4 - t_3)}{C(t_2 - t_1) - (b - a)t_2 - aL_1 + bL_2} \quad (1)$$

The amount of cooling due to the sensible heat of the air with the water vapor it carries is $Wc(t_2 - t_1) + Wa(t_2 - t_1 + L_2 - L_1) = W[a(L_2 - L_1) + (t_2 - t_1)(c + a)]$; and the amount due to evaporation and carrying away of sensible heat in this water vapor is $W(b - a)L_2 + W(b - a)(t_3 - t_2) = W(b - a)(L_2 + t_3 - t_2)$.

Therefore the per cent of cooling due to evaporation in terms of the total cooling is

$$W(b - a)(L_2 + t_3 - t_2) \div \{W(b - a)(L_2 + t_3 - t_2) + W[a(L_2 - L_1) + (t_2 - t_1)(c + a)]\}$$

or per cent cooling due to evaporation $=$

$$\frac{(b - a)(L_2 + t_3 - t_2)}{(b - a)(L_2 + t_3 - t_2) + a(L_2 - L_1) + (t_2 - t_1)(c + a)} \quad (2)$$

Substitution in equation (2) the values found in practice will show in general over 90 per cent of the cooling obtained is due to evaporation of part of the water. Since this is so, it is at once evident that the amount of cooling is practically determined by the evaporation.

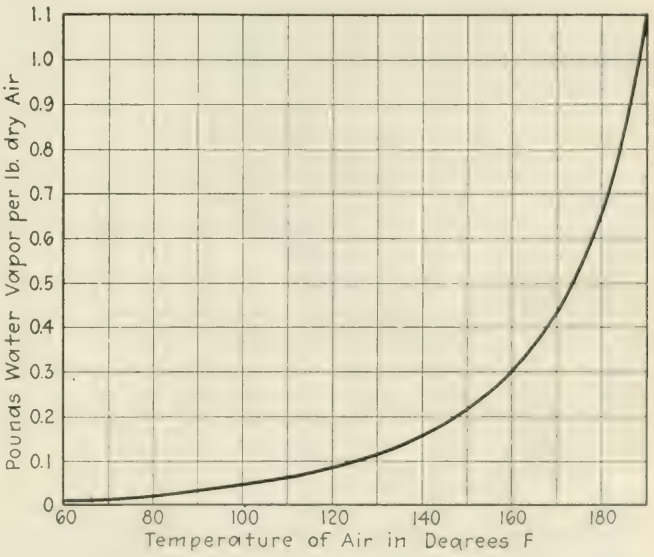

FIG. 1. WATER VAPOR IN SATURATED AIR AT 30 INCHES BAROMETRIC PRESSURE

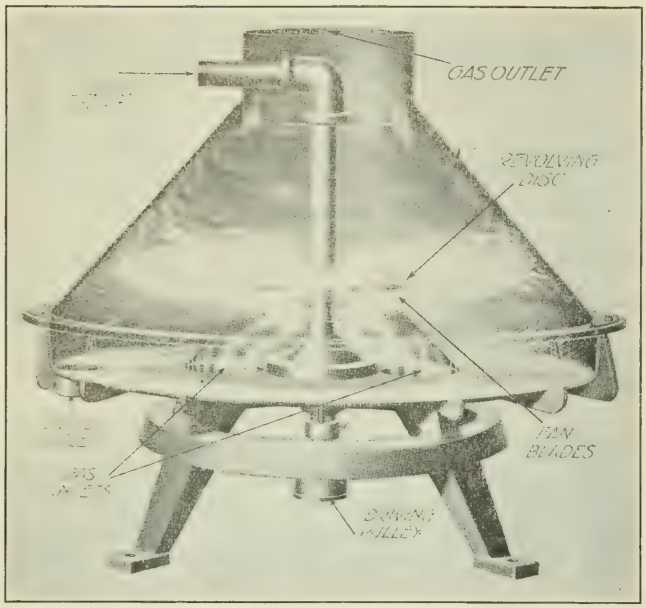
The term "loss by evaporation," as frequently used in referring to cooling systems, is, to say the least, misleading. The amount of liquid actually vaporized is properly a measure of the cooling capacity of the system. In reality the only way that water can be actually lost in a spray system or cooling tower is by being carried away mechanically as entrainment or spray.



PHANTOM VIEW OF CECO SPRAY SYSTEM IN OPERATION

If the amount of water passing through the system per unit of time is known in addition to the above data, the volume of air handled may be readily computed. The above formula (1) gives the weight in lb. of dry air, and this may be converted to cubic feet at the temperature t_1 and particular barometric pressure existing. This air will carry with it Wa lb. of water vapor. From steam tables the specific volume of water vapor (steam) at the same temperature and pressure may be found. The product of Wa times this specific volume will give the corresponding cubic feet of water vapor. The sum of the volumes of dry air and water vapor so obtained will give the volume of atmospheric air entering the system. Or, if the air is saturated, the specific volume of the mixture may be obtained from published tables, and the product of $W + Wa$ times this specific volume will give the cubic feet of air.

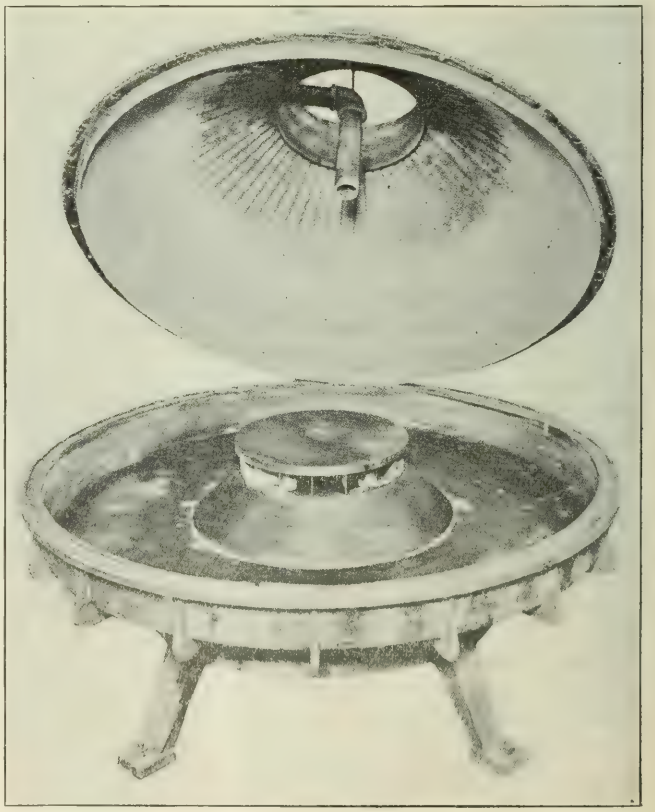
Factors Governing Capacity

The capacity of any cooling system working on air of given temperature and humidity will be dependent on the design of apparatus, the temperature of the exit air, and the amount of air handled.

The design of the apparatus should aim to give complete saturation of the exit air, and to discharge this air at as high a temperature as possible. That is, the counter current principle should be employed, and the intimacy and time of contact between the water and air should be sufficient to cause the maximum possible evaporation.

The temperature of the exit air is of prime importance, as this determines the amount of evaporation that can take place per unit of air handled. Fig. 1 shows the pounds of water vapor carried by 1 lb. of dry air when saturated at different temperatures. The amount of water vapor which can be held by the air at a given temperature is such that the partial pressure of the water vapor in the air just equals the vapor pressure of the water. If less water vapor than this is carried by the air, it is present in it as superheated steam, since it is present at a higher temperature than saturated steam would be at that particular pressure, i.e., the partial pressure of the water vapor. Ordinarily we think of this as merely unsaturated air, or air of a certain per cent humidity. It is not possible for the air to carry more water vapor than that indicated. That is, the exit air cannot be supersaturated unless the temperature is high enough so that the water would boil freely at the absolute pressure existing in the apparatus. For complete saturation of the exit air the amount of evaporation, and hence the cooling effect, will depend on the temperature of the exit air, and will increase very rapidly with increase in temperature. If the exit air is only partially saturated, then it is equally true that the higher the exit temperature of the air, the greater will be the cooling effect.

The cooling effect will always be increased by increasing the amount of air handled, but the increase will be directly proportional to the increased amount of air handled if, and only if, the degree of saturation and temperature of the exit air are maintained constant. However, for a given installation, doubling the volume of air handled will not double the cooling effect, for increasing the amount of air will increase the cooling, and hence the exit air will leave at a lower temperature. So that even if saturated, the air at the lower temperature will carry less water vapor per unit of air, and hence will have caused less evaporation or cooling effect per unit of air handled. It will not be unusual to find that doubling the volume of air will cause an increase in the cooling effect of only 50 per cent instead of the 100 per cent that might have been expected. This may be offset by increasing the flow of water so as to maintain the same high temperature of exit air. In general, the cooling capacity of any system may be increased (as measured by B.t.u. extracted and not by the temperature of the exit water) by increasing the flow of water so as to raise the temperature of the exit air. So, while it would appear contradictory, it is true that



TWELVE-INCH CECO SPRAY WITH COVER RAISED

greater cooling capacity will be obtained with higher temperature of exit water.

Tests on the Ceco Spray System

The writer has had occasion to run some tests on a new type of spray system manufactured by the Chemical Equipment Co. The accompanying cuts show the construction quite well. This spray system tested consists essentially of a revolving disk, carrying radial fan blades on its under side, and housed in a metal cone. The disk is rotated at approximately 1,800 r.p.m., from 2 to 3 hp. being required according to volume of water handled.

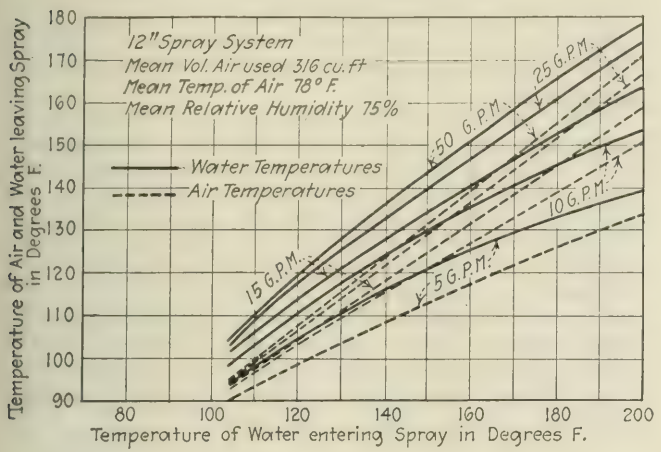


FIG. 2. RELATION BETWEEN TEMPERATURE OF ENTERING WATER AND TEMPERATURES OF EXIT WATER AND AIR

Water, or other liquid to be cooled, is brought upon the center of the disk through a fluid inlet pipe. The liquid is distributed evenly over the surface of the disk, but cannot travel at quite the rate of speed of the disk itself and consequently the liquid is broken up into small drops, each one of which is set spinning about its own axis. These drops, when leaving the disk, also tend to travel about the disk axle, and the combination of the two motions combines to give a planetary motion to each drop. A drop, as it proceeds outward from the disk, will subdivide into finer drops, to each of which is likewise imparted the planetary motion. The finer drops again subdivide, and so on. Thus a liquid curtain is built up in the spray system, thin, but dense near the edge of the disk, and becoming thicker and less dense at the cone wall.

Air is drawn in through the bottom of the spray system and discharged from the fan blades at a velocity slightly less than that of the liquid. The air is so directioned that it and the liquid curtain meet at a small angle, and due to the greater velocity and density of the liquid curtain, the direction of the air is changed without the possibility of its tearing holes in the liquid curtain, and it thoroughly intermingles with the liquid until the cone wall is reached. At this point the liquid is deflected downward, and the air upward. Due to the rotation of all particles about the disk axis, the air in its travel upward takes the path of a long spiral, and because of the centrifugal action, all entrainment is thrown out by the time the air exit is reached. The air is thus discharged from the top of the cone, whose function is to separate out any drops of liquid and so prevent entrainment; while the cooled liquid is discharged from a large connection below the cone.

The spray system was set up in the laboratory so as to permit measuring the volume of water used, the temperature of entering and exit water, and wet and dry bulb temperatures of the entering and exit air. Calibrated thermometers were used. Several sets of cooling tests were made, using a constant flow of water for each set, and varying the initial temperature of the water. Each test lasted about 11 min., ten readings of all thermometers being taken at even time intervals. These readings were averaged, and the proper thermometer corrections applied to get the true readings. From these data and the gallons of water cooled per minute, the volume of air handled and the cooling effect in B.t.u. or deg. F. could be obtained.

Temperature Changes With Varying Flow of Solution

Fig. 2 is interesting in that it shows the actual capacity of a commercial machine with a given volume of air, and as an illustration of the fundamental principles involved. If it were desired to cool large amounts of water for condenser or other work, the most economical operation would be to use a high rate of water flow and several machines in series, each discharging its saturated air separately into the atmosphere. But if it were desired, as in some chemical industries, to cool a small amount of liquid very quickly, a small flow of liquid should be used to give the desired effect, at the sacrifice of capacity. These statements in a qualitative way are general, and applicable to any type of spray or tower system.

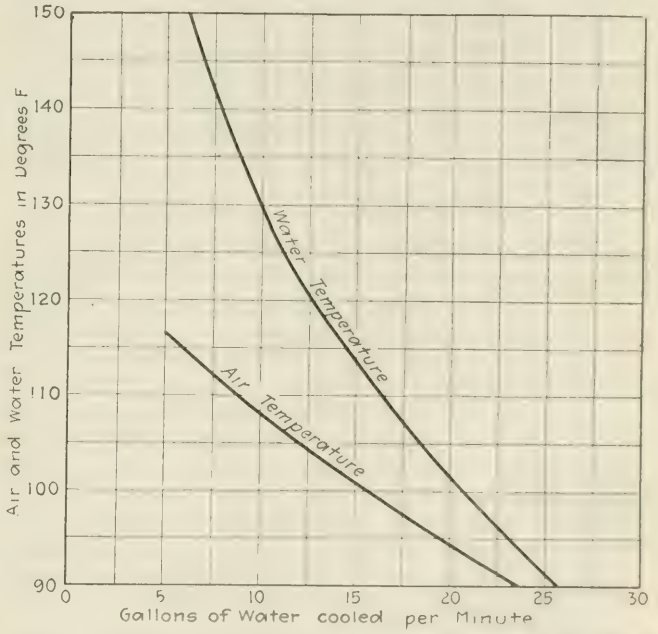

FIG. 3. MINIMUM INITIAL TEMPERATURE AND VOLUME OF WATER REQUIRED TO GIVE COMPLETE SATURATION OF EXIT AIR

Fig. 3 shows the minimum initial temperature and volume of entering water that give complete saturation of exit air. The corresponding temperatures of exit air are also plotted on this curve. For smaller volumes or lower initial temperature of entering water, the air will escape without causing maximum possible evaporation or cooling per unit of air used. To obtain maximum capacity of the machine it should be operated so as to give a saturated exit air, that is, if the initial temperature of the entering water is plotted against the water flow, the point should fall in the area to the right of the curve as drawn. There may be cases, however,

where the maximum capacity is not the main objective, and where for special reasons it would be desirable to operate to the left of the curve, that is, with the exit air not completely saturated.

Effect of Variation of Volume of Air

Fig. 4 shows the effect of increasing the volume of air handled. This was done in these experiments with the aid of a booster fan. The effect is exactly what could be predicted from fundamental considerations.

Another interesting feature brought out by the tests was the resistance of the liquid curtain to passage of the air. It was expected that just as increasing the liquid flow in a tower system increases the resistance to the passage of air, so increasing the water flow would have the same effect with the system under test. The reverse was found true. Increasing the flow from zero up to 60 gal. of water per min. caused a Pitot tube in the air inlet duct to show a marked increase in the volume of air handled. The water undoubtedly exerts a pumping or fan effect on the air—a very interesting characteristic. The tests also showed that there was no liquid entrainment in the exit air for any rates of flow of water and air used.

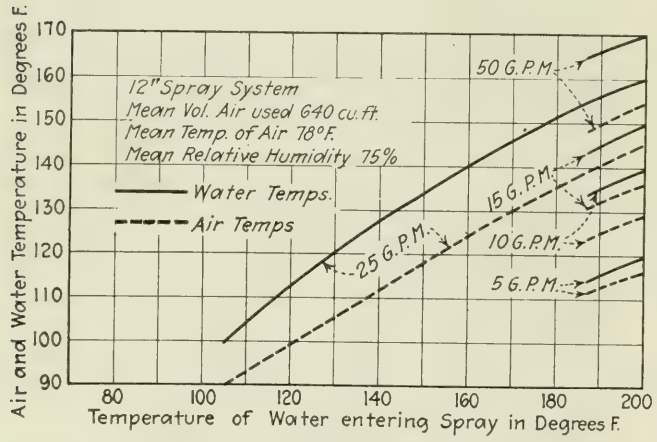

FIG. 4. RELATION BETWEEN TEMPERATURE OF ENTERING WATER AND TEMPERATURES OF EXIT WATER AND AIR, WITH INCREASED AIR VOLUME

The writer is particularly interested in the possible applications of the spray system in the chemical industries for crystallizing work. In many cases, hot solutions are run out into vats to cool slowly, the object being to form large uniform crystals. Large vats are required, and crystals of uniform size are difficult to obtain. Now, if such a solution could be run through a spray system (of a non-clogging type such as the one under test) and rapidly cooled to just the temperature of initial crystallization, and if this were accompanied by violent agitation (as obtained in this case), a large number of very small seed crystals could be started. If this liquid just starting to crystallize and containing many fine seed crystals were run to a vat to stand, the seed crystal should grow with reasonable uniformity, giving a well-graded product of large crystals. The saving in vat capacity, due to the much lessened time required for cooling the liquid with such a system, would be enormous. Moreover, concentration in the particular evaporators used would not have to be carried quite so far, as the evaporation in the spray system would remove a certain amount of water.

Chemical Engineering Laboratories,
University of Michigan.

Some Metallurgical Features of the Liberty Engine

By R. S. Archer

THE development and manufacture of the Liberty engine has afforded a most unusual opportunity for the study and correlation of knowledge concerning the materials of engineering construction as applied to gas engines. The design and materials specifications of the Liberty engine were based to a large extent upon the best modern practice, and the building of the engine was undertaken by some of the best manufacturers of this country. This applies not only to the principal contractors who turned out the finished engines, but also to the many manufacturers of parts and accessories.

While most of the metallurgical work connected with the Liberty engine was concerned with parts made of steel, the experience gained with these parts and the general principles regarding the suitability of various materials for definite uses should be of value to those engaged in the production of any material for the building of gas engines. Time is too short to cover any great proportion of the many interesting metallurgical questions that arose during the Liberty program. I shall try to point out what seem to me to be outstanding principles of a general nature, and to cite examples in illustration of these principles.

Specifications and Difficulties in Their Fulfillment

The design and materials specifications of the engine were drawn up with a sort of slogan that the best was not good enough. This was due quite largely to the insistence by many people, both in Europe and in this country, that American manufacturers were not capable of building quality engines. The high standards set up were also influenced by the strictness of the foreign specifications and inspection.

It was not long until experience showed that this rule would have to have exceptions if any quantity of engines was to be produced. One of the first difficulties encountered was the machining of the cylinders. It was necessary to remove about ½ in. of metal from the cylinder wall and the Brinell hardness limits specified were 350 to 400. This made the cylinders almost non-machinable. A similar difficulty was encountered in the case of the connecting rods, the hardness of which was about 300 Brinell, and was even worse than in the case of the cylinders, because this was milling machine work instead of a lathe job.

Lowering of Specified Brinell Hardness

One of the first concessions to the necessities of manufacturing was in the case of the cylinders. A little consideration showed that in the operation of welding the intake and exhaust elbows onto the cylinders, which was done after the cylinders had been finish heat-treated, the top of the cylinders would probably be heated up sufficiently to draw the hardness below the specified minimum of 350. A casual inspection of the welding room was enough to show that at least some of the cylinders were being heated to a temperature which would certainly reduce the hardness in places below 350. In order to test the mechanical strength of the finished cylinders, some of them were fitted with a piston in a tensile testing machine and filled with

soft soap. The bursting load found by this means gave ample assurance that the hardness could safely be reduced. The hardness limits finally established were 217-255. The chief factor governing the hardness was machinability rather than strength.

The next step of importance was the lowering of the hardness of the connecting rods. This change encountered considerably more opposition than the change in the cylinders, both because the manufacturing necessity was not so great and also because the connecting rod was considered a more highly stressed part. The situation as regards machining was rather acute, however, because the number of milling machines required for milling the channels in the connecting rods was rather larger than was easy to obtain at the time.

Some tests were run on soft connecting rods by equipping Liberty engines entirely with soft rods. One set of the usual rods was used which had not received final heat treatment and had a Brinell hardness of only 187. No failures occurred. Another engine was equipped with a set of straight carbon steel rods having a hardness of 250. This engine was also run successfully without any failures. As a result of these tests and of the obvious advantage from the standpoint of production the specified Brinell hardness was lowered from 286-321 to 241-277. This meant a change in the minimum elastic limit from 130,000 to 105,000 lb. per sq.in. No subsequent trouble was experienced as a result of this change.

Changes in Originally Specified Screw Machine Parts

Another change of the same nature, but by far the most difficult of all changes to get past the conservatism at Washington, was the substitution of screw stock for the high grade low-carbon steel which had been specified for screw machine parts. It should be explained that the term "screw stock" usually signifies a low-carbon steel of rather high phosphorus and sulphur content. This high sulphur and phosphorus confer upon the steel the property of cutting freely, although the Brinell hardness is actually higher, and steel of this type is almost universally used for screw machine products. The designers of the Liberty engine did not consider that this material was sufficiently reliable for their purposes and consequently specified a first-class open-hearth low-carbon steel with the phosphorus and sulphur limited to 0.045 per cent. At the same time the limits specified on threads were extremely close. It was found practically impossible to produce large quantities of screw machine parts with the required accuracy of thread from the low-sulphur low-phosphorus steel. Such threads could be produced from this steel if new dies were always available, but the die-producing capacity of the country was limited and very hard pressed, so that it became practically necessary to secure a free-cutting steel. In the face of much opposition the specification was finally changed on a large number of lightly stressed screw machine parts to permit the use of low-carbon steel having a sulphur content of 0.06 to 0.09 per cent, and the situation was greatly relieved.

The changes just noted were probably the most important made and were typical of a number of other changes of a similar nature. These changes were all an expression of the general tendency to specify a material which could be manufactured into the necessary parts, rather than one which would be ideal if it could be manufactured.

As time went on and the cry for increased production of engines became more insistent, further changes in material were made to facilitate manufacture, although they were not of so urgent a nature as the above changes. The time had been reached when such changes could be safely made, because the engine was much better understood, and the original factors of safety which had been employed, which were largely factors of ignorance, could be reduced. Two changes in materials of this type were the substitution of chrome-vanadium steel for chrome-nickel steel for connecting rods, and the substitution of a steel of reduced nickel and chromium contents for the crankshaft. The high chrome-nickel steel originally used for the connecting rods is particularly difficult to handle, especially in the forging and heat-treating operations. This is due to a large extent to the fact that nickel decreases the welding power of steel, thereby causing cracks once formed to remain open, and to the semi-air hardening properties of the steel which cause it to stiffen up severely if allowed to cool to too low a temperature during the forging operation. The connecting rod problem became so serious that in May, 1918, connecting rods had become the proverbial "neck of the bottle." At least this was said to be the case, and at a conference of the American Drop Forgers' Association it was decided to substitute a chrome-vanadium steel. This was done by most of the manufacturers. The result of this change was a faling off within six weeks of the average forging scrap on connecting rods from about 55 per cent to less than 10 per cent.

A change of the same nature was the substitution of S. A. E. steel 3240 for X3335 for crankshafts, because of the greater ease in forging and heat treating and the greater freedom from defects arising from the original steel ingot.

Tendency of Specification Changes

The tendency exemplified by these changes in material and lowering of the physical properties required seems to be characteristic of modern engineering thought and may be summed up in this way:

First, there is no use in specifying a material for production work which cannot be produced with the manufacturing facilities available.

Second, and rather more important because less obvious, is the tendency to prefer uniformity and reliability of product to a less uniform and less reliable product, which may have superior properties when it is at its best.

Significance of Manufacturing "Scrap"

There has been a rather inadequate appreciation of the engineering significance of manufacturing "scrap." It has pretty generally been considered that a high percentage of scrap simply means high cost and occasionally insufficient production. The evils of scrap material go much further. Scrap is material containing defects which have been found. A high percentage of scrap means a high percentage of detectable defects, and *implies* a high percentage of defects which are not detected. This may be illustrated by a consideration of the Liberty connecting rod. Most connecting rods were first made of S. A. E. steel, X3335 or X3340. These are steels containing approximately 3 per cent nickel, 0.80 per cent chromium with 0.35 and 0.40 per cent carbon. As mentioned before, this steel is difficult to handle in every step of its manufacture.

This includes the melting, casting, rolling, forging and heat treating. The defects arising from the difficulties encountered in the steel mill are typified by the snowflakes and hairline seams found in the finished stock. In forging, the steel is very sensitive to burning if it is slightly overheated. It also cracks quite easily and has the property of not welding shut on further application of work. These properties result in the production of a high percentage of scrap forgings, meaning forgings in which the defects are visible. The same causes which produce these visible defects also produce a correspondingly high percentage of invisible defects which are difficult to detect. In order to detect overheating it was required that small lugs be forged on the side and end of each connecting rod and that these be broken off after the final heat treatment in order to test for the coarse grain characteristic of overheated steel. These lugs could not, however, vouch for the quality of the entire rod, especially of the thin section in the channel, which was very apt to be overheated in the operation of heating up the big end of the rod. Similarly, the minute cracks formed occasionally in forging were sometimes completely hidden and there was no way of finding them in the finished connecting rod. When the change was made to chrome-vanadium steel, in spite of the fact that chrome-vanadium steel at its best is inferior to chrome-nickel steel at its best, it is very probable that the percentage of inferior rods which passed the final inspection and went into engines was less than when the chrome-nickel steel was used.

This is merely one example of a principle which applies to any manufactured article; that is, the greater the percentage of apparently perfect material that can be produced, the greater will be the percentage of truly perfect material and the less will be the probability of hidden defects.

Uses and Abuses of Alloy Steels in the Art of Producing Engineering Materials

This principle is not as yet widely accepted by the engineering profession, but that its acceptance is growing is shown by an increasing tendency to specify straight carbon steels where alloy steels were formerly used, not in order to cheapen the product, but to improve its quality. It is still true that alloy steels, some of them of a very fancy composition and with very extravagant claims made for their properties, constitute a strong selling point for the steel salesman, but I believe the tendency is against these products in favor of a product which can be made with greater uniformity and certainty. This does not mean that it is advisable to avoid alloy steels or other materials of a superior quality simply because the methods of fabricating them have not been fully developed. Such an idea would of course stifle advances in the art of producing engineering materials, nevertheless there are some materials which are inherently more difficult to produce satisfactorily than others. For example, I do not see how any advance in the art of manufacturing alloy steels can overcome the fact that nickel steel is difficult to weld and that cracks once formed in a forging will remain open; or, to go even farther back than this, that cracks formed in the ingot will also remain open and be found in the finished product as snowflakes or other defects. The alloy steels must by all means be used where material of the very highest properties is necessary. There are also cases where economy requires the use of alloy steels because of the wider range of heat-treating temperatures, and the greater ease of machining.

Strength of Materials

Let us consider briefly the steps in engineering design, as applied to the strength of materials. First, the maximum working stresses of the part in question are calculated; a factor of safety is assigned and a material chosen whose properties are expected to give the required factor of safety when the part is made of the proper dimensions. This method, which is followed so largely in structural engineering, does not hold to such an extent in automotive design. In building automobile engines and especially airplane engines, the practice has been to start with a part of sufficient size and made of a material of sufficient strength to give considerable assurance of safety, then to gradually reduce the dimensions of the part or the physical properties of the material to the lowest point which experience shows to be safe. I have been told that one of our foremost designers of airplane engines determined the limiting sizes of his important parts by running destruction tests on engines containing parts of successively smaller dimensions. When the dimensions had been reduced to such an extent that the part in question failed in service, it was known that the dimensions had to be increased or a better material used. In other words, the engineering of automobile and airplane engines has been largely a cut-and-try proposition.

Factors of Safety

The factor of safety which is used in engineering design is largely a factor of ignorance; ignorance as to the actual stresses developed in service, and ignorance concerning the true physical properties that will be obtained in the fabricated part. The nature and extent of the working stresses developed are investigated by the process of cut and try to which I have referred. By this process there is obtained a fairly exact idea of the limiting dimensions of the part, assuming definite physical properties in the material to be used. These minimum dimensions must then be increased in proportion to the uncertainty regarding the physical properties which actually will be obtained. This uncertainty, and consequently the dimensions and weight of the part in question, can be reduced by using a material which is more certain to yield uniform properties and less likely to develop flaws which are hard to detect in inspection. It is not the average physical properties of the material of a given piece of mechanism that determine the quality of the machine, so much as it is the maximum deviation from the average. For example, it may be better engineering practice from the standpoint of quality alone to use a straight carbon steel with an average elastic limit of 90,000 lb. per sq.in., in preference to a chrome-nickel steel having an average elastic limit of 125,000 lb. per sq.in., if the conditions of manufacture are such that the percentage of parts made of the straight carbon steel which fall dangerously low is less than the percentage of the chrome-nickel steel parts which fall dangerously low.

Conclusion

To sum up the foregoing observations, the effect of the Liberty engine program upon the selection of engineering materials has been to emphasize the importance of uniformity of product and ease of manufacture.

Loss Due to Carbon in Furnace Refuse*

By C. H. Berry

IT IS common to treat as pure carbon the combustible which passes through the grates or over the dump plates together with the ash. The losses resulting from the failure to burn this lost coke depend upon two factors—the percentage of ash in the original coal and the percentage of carbon in the furnace refuse. Both of these quantities are determined by laboratory analysis of samples of the coal and refuse respectively. Knowing these values, the heat loss may be computed from the following equations:

$$\textit{Per cent ash in refuse} = 100 - \textit{per cent carbon in refuse.}$$

$$\textit{Lb. refuse per lb. coal} = \frac{\textit{per cent ash in coal}}{\textit{per cent ash in refuse}}$$

The weight of carbon lost is then

$$\textit{lb. refuse per lb. coal} \times \frac{\textit{per cent carbon in refuse}}{100}$$

$$= \frac{\textit{per cent ash in coal}}{\textit{per cent ash in refuse}} \times \frac{\textit{per cent carbon in refuse}}{100}$$

This may be written:

$$\textit{Lb. carbon lost per lb. coal fired} = \frac{\textit{per cent ash in coal}}{100} \times \frac{\textit{per cent carbon in refuse}}{100 - \textit{per cent carbon in refuse}}$$

Since 1 lb. carbon has a heating value of 14,600 B.t.u.,

$$\textit{Lb. carbon lost per lb. coal fired} \times 14{,}600 = \textit{B.t.u. lost per lb. coal fired.}$$

The percentage heat lost will be

$$\frac{\textit{B.t.u. lost per lb. coal fired}}{\textit{Heating value of coal as fired}} \times 100.$$

These formulas have been combined in the accompanying alignment chart, in which the left half gives the pounds of carbon lost per pound of coal and the B.t.u. lost per pound of coal, for given values of the percentage of ash in the coal and the percentage of carbon in the refuse. The right half of the chart gives the per cent of heat loss from the known result found from the left half of the chart together with the known heating value of the coal.

An examination of the chart will indicate that the extent of this heat loss may be considerable. For example, if we fire a coal containing 12.5 per cent of ash, and if the resulting furnace refuse contains 38.7 per cent of carbon, the weight of carbon thus lost will be 0.079 lb. of carbon per pound of coal fired. This results in a loss of 1160 B.t.u. per pound of coal fired. If the heat value of the coal is 12,700 B.t.u. per lb. this heat loss will be 9.2 per cent of the heat value of the coal, which is the basis used for figuring all the heat losses in the furnace, boiler and setting. It can readily be seen that for higher percentages of carbon in the refuse this loss may be an even larger proportion of the heating value of the coal. It should also be noted that a higher ash content of the coal, with the same percentage of carbon in the refuse, will also give a larger heat loss. This is one reason, though a minor one, why high-ash coals do not permit as high boiler efficiencies as obtainable with higher grades of fuel.

The extent to which this loss may be reduced depends upon many things, but it seems that under fair operating condtions it is reasonable to expect not more than 20 per cent. of carbon in the refuse, and under good conditions not exceeding 10 per cent. The corresponding heat losses will then be less than 5 per cent and may be as low as 1 per cent under favorable conditions. A series of 77 tests conducted at the St. Louis plant of the United States Geological Survey showed an average heat loss a little under 5 per cent, and these tests were made under oprating conditions, using coals of a wide range of quality.

Practical suggestions for reducing this loss include: Avoidance of unnecessary barring and raking of fires, an ample (but not too vigorous) supply of air at the dump plate, and the use of clinker grinders.

Unfair Competition by Use of Trade Mark—Extent of the Use of Trade Mark

THE rights of one to adopt and use names in the prosecution of one's business is very broad, but must be limited when such use injures the business of others. Especially when the use of a word offers unfair competition with another who has a prior right to its use the courts will interfere to protect the latter's interests. But the right to exclusive use of a trade mark is not unlimited. In a recent case at special term the Supreme Court of New York County enunciated several rules affecting these principles. (177 N. Y. S., 713.)

The plaintiff in the case is a trading corporation organized in 1907, at that time succeeding to the business of a partnership formed in 1900. It is chiefly engaged in trade with foreign countries, dealing in a great variety of merchandise, paper products appearing to be its chief lines. It seems to be rapidly extending its lines and business and is the owner of a trade mark, consisting of the word "Caravel" with the picture of a sailing vessel of the ancient type. This word was originally used only on paper, but as the business was expanded the trade mark was more widely used, so that it has been affixed to inks, ink-making materials, and various other goods. Other goods have been shipped and to them the word has been applied as a designation of a brand in the invoices. Goods of many other descriptions have been shipped, and many other shipments of similar goods have been made without the use of either the name or the mark.

Name Complained Of Chosen Innocently

Now, in 1916 the defendants in this case formed a partnership and began doing business under the trade name "Caravel Company." The firm name was chosen innocently. At first the firm business was confined to dyestuffs, but later it dealt also in drugs and chemicals. Its business also was largely done with foreign countries. In 1918 the defendant corporation was formed and the firm name was adopted as the corporate name. The business of the firm was transferred to the corporation and the firm dissolved. The partners became officers of the corporation, which continued the business in dyestuffs, drugs, and chemicals. It also extended its dealings to general merchandise. It has used a label upon which its corporate name is printed, together with a representation of a sailing vessel of the caravel type. The catalogs, advertising matter, and stationery bear the same name and drawing. Its label has been affixed to certain classes of goods which plaintiff has been accustomed to ship without its trade mark. It was shown to have attempted to do business in paper and in other classes of merchandise which plaintiff had dealt in previously under its trade mark. Prior to the organization of the corporation, but after the formation had been decided on, plaintiff notified the firm that it was the owner of the Caravel trade mark and requested the firm to discontinue the use of the word "Caravel," both in its firm name and otherwise, in connection with the sale of its goods. At this the firm had a search made of the records of the Patent Office. This search showed the particular classes of merchandise for which plaintiff's trade mark had been registered, and also that trade marks consisting of the word "Caravel," both with and without the representation of a sailing vessel, had been registered by other persons for goods of various descriptions. The defendants refused to abandon the use of the name "Caravel Company" or the use of their labels, and plaintiff asked for an injunction against them.

The essence of the wrong complained of is unfair competition, said the court. The general principles applicable were stated as follows: "A trade mark is acquired by adoption and use as such. It must be affixed to the goods. The right of user is in its very nature an exclusive right. Unauthorized use or imitation by a competitor may be restrained. The right to exclusive use of the trade mark is not unlimited. Its use upon one or more commodities does not give the right to use it upon all. But neither is the right confined to the precise species of goods to which the mark has been affixed. It extends to other goods of the same class; and where the general uses or characteristics of the articles are similar or analogous they are within the same class. A trade mark used by a manufacturer of picks and hoes may not be used by a competitor upon shovels; . . . nor may a manufacturer of tooth brushes appropriate the mark used by another on hairbrushes.

Test of Legal Trade Mark

"Prior appropriation to the species prevents a subsequent competitive use upon a class in which the species is included. The test is whether an intending purchaser would be likely to mistake the origin of the goods. The purpose is to prevent the palming off of the products of one trader as that of another; and where the danger of confusion and deception is manifest, it is unnecessary to prove that either has in fact occurred. The principles thus stated as applicable to trade marks apply equally to marks which are not technical trade marks and to trade names. So the use of a corporate name may be enjoined, if confusion or deception is likely to result from its use by a dealer in competitive goods."

Applying these principles the court concluded:

First—The plaintiff has acquired the exclusive right to use the Caravel trade mark on the various classes of goods upon which it or its predecessor was the first to affix and use that mark.

Second—The plaintiff did not acquire any exclusive right to the use of the name or mark by the mere use of the name "Caravel" in its invoices.

Third—The use of the trade mark upon certain classes of goods cannot upon any theory of extension of user give to plaintiff the exclusive right to use it upon all the varied classes of general merchandise in which it has dealt, or in which it may hereafter choose to deal.

Fourth—Though the use of a corporate name may be restricted and enjoined in a proper case, there is no ground upon which the defendant company can properly be required to discontinue the use of its corporate name.

Whether the defendant corporation should be allowed to do business in its corporate name in those classes of goods upon which plaintiff has the exclusive right to use the Caravel trade mark was an important question in the case. The court said that if

the business of the defendant corporation was confined solely to such goods, it would be restrained from doing business under the name "Caravel Company." But the defendant corporation deals in goods of a very diversified character. Hence the court held that defendants should be restrained from dealing in or advertising, under the name "Caravel Company" or any other similar name, those goods as to which plaintiff has established the exclusive right to use the Caravel trade mark. So judgment was given accordingly.

Injuries to Workmen From Noxious Dust and Gases —Employer's Duties Set Forth

Compensation acts are disposing of much of the negligence cases formerly arising under the common law. However, exceptions and conditions still permit of many cases. In Indiana, which has such an act, comes a case wherein an employee brings an action against his former employer to recover damages for injuries to his eyes and health through the employer's negligence in permitting the escape of noxious dust and gases from its mixing room into the room where the employee was working. (Brunson vs. Macbeth-Evans Glass Co., 122 N. E., 438.)

From the facts it appears that the employment extended over several years and the injuries were a general resulting condition some time after the employment. In this complaint the plaintiff charged that he first worked for defendant as a gatherer of molten glass and later as a glass blower, working in the blowing room; that adjacent to the blowing room defendant maintained a room known as a mixing room, where it mixed products used in the manufacture of glass in large troughs; that among the poisonous substances thus mixed were suboxide of copper, oxide of tin, white sand, pearl ash, saltpeter, arsenic, magnesia, soda ash, lime, carbonate of soda, niter, charcoal, and lead, which said substances were at all times mixed dry; that all of these substances were injurious to human beings who came in contact with them, and were especially injurious to the eyes of such persons. The plaintiff further charged that from the mixing of these poisonous substances in a dry and powdery state, there arose a cloud of dust, which, if not confined and prevented from blowing from the mixing room into the other rooms of the factory, would permeate the air of these parts and injure the eyes and eyesight of the workers there; that during the time of his working in the blowing room his eyes and eyesight became affected and injured from this dust, though at the time he did not know that they were, or would become, injured from it.

The defendant was charged with knowledge, or by the exercise of proper care should have known, of the injurious and deleterious effect of this dust upon the eyes of human beings. It was charged with negligence in that there were doors in the mixing room for the purpose of keeping it closed, but defendant permitted the doors to be open and the dust to escape through these doors into the blowing room, where plaintiff worked; that defendant negligently suffered the partition shutting off the mixing room to be loose and insecure and allowed large cracks and openings to remain in the same so that dust and gases from the mixing troughs and poisonous chemicals escaped into the blowing room and into the plaintiff's eyes and face. All of which injured plaintiff's general health and his eyes and caused cataracts to form over them, permanently impairing his eyesight.

In another count of the complaint negligence was charged in that the employer did not instruct the employee as to the danger to his eyes when they were, as during the course of the employment, exposed to intense radiated heat.

Another count was the alleged negligence of defendant in causing plaintiff to work exposed to great heat, when run down physically.

Plaintiff obtained a verdict and judgment for damages upon the trial. On appeal the higher court held the complaint stated a good cause of action, but granted defendant a new trial on an erroneous instruction regarding defendant's allowing plaintiff to work where his eyes were being subjected to radiated heat while in a run-down physical condition.

It should be valuable to employers to know what the court said regarding the first cause of the complaint. The duty of the employer in protecting his workmen is put into a statute that is more than declaratory of the common law. This statute provides as follows:

Statute Defines Employer's Duties

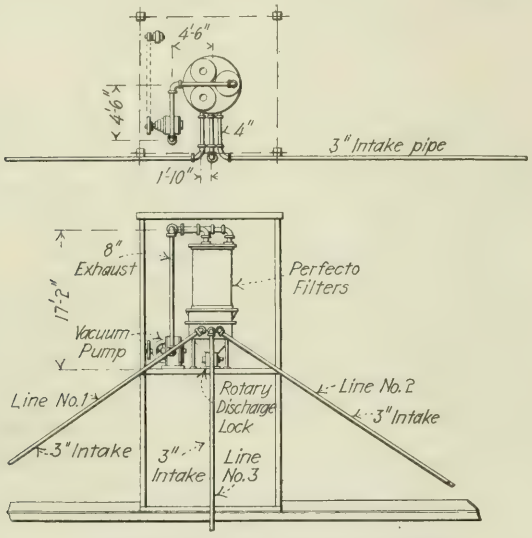
"It is hereby made the duty of all owners, . . . corporations, agents or persons whatsoever, engaged in the care, operation, management, . . . of any shop, factory or business of whatsoever kind, . . . and generally it shall be the duty of all owners, managers, operators, contractors, . . . and all other persons having charge of, or responsible for, any work, mechanism, machinery, appliance, building, factory, plants, means, employment, or business of whatsoever nature, involving risk or danger to employees, . . . to use every device, care and precaution which it is practicable and possible to use for the protection and safety of life, limb and health, limited only by the necessity for preserving the reasonable efficiency of such structure, ways, work, plant, building, factory, . . . appliances, apparatus, or other devices or materials, without regard to additional cost of suitable materials or safety appliances, or safe conditions or operations, the first concern being safety to life, limb and health."

In view of this statute the court asked: Did the defendant "know that the continued breathing of the dust and fumes as complained of was injurious to the workmen? If it did not so know, could it, by the exercise of reasonable care and caution in the premises, have so known? If it did know of the poisonous nature and deleterious effect of these gases and dust on workmen, and permitted their continued exposure thereto, it was negligent, as a matter of law. . . . If it did not have actual knowledge of the foregoing facts, but by the exercise of reasonable care in the premises could have so known, and yet permitted the continuation of such dangerous condition, as to which condition the jury were told in said instruction that they must find as a fact 'that said partition was allowed by defendant to become in disrepair, and was not properly constructed, and that doors and windows were left open so that dust was allowed to arise and blow through said crevices and cracks and said doors and windows in said partition, into and upon the workmen and the plaintiff, at work in said blowing room,' then, this fact being found against defendant, it was guilty of negligence in not so ascertaining that fact, and in permitting further unnecessary exposure of its employees thereto."

Dracco System at Armour Fertilizer Co.

The accompanying illustration shows the operation of a Dracco nozzle directed by a single workman in removing dry blood, tankage, and other materials used in the manufacture of fertilizers at the Jacksonville plant of the Armour Fertilizer Co. Formerly cars were unloaded by hand and material lifted by bucket elevators, a process most tedious and unsanitary and at the same time expensive.

Three ascending intake pipes terminate at the lower end in flexible steel hose, and intake nozzles make it possible to unload three cars without switching. These steel pipes lead upward to and are connected with a receiver where all the coarse particles are settled, this



OPERATION OF A DRACCO NOZZLE

settlement being accomplished by a reduction in the air velocity.

The extremely fine dust passes upward into filter units of the Perfecto type, placed directly on top of the receiver. This settling and filtration collects all the material and it is carefully discharged through an especially designed rotary lock as fast as unloaded. The air which has been entirely cleaned by its passage through the filters is sucked through a high-efficiency vacuum pump. Operation depends upon a high vacuum, which may be anywhere from 5 in. to 25 in. of mercury according to distances, material, capacity, and other local conditions.

Scoop Conveyors for Coal Storage

A portable conveyor developed by the Portable Machinery Co., Passaic, N. J., shown in Fig. 1, has become quite popular as a means of handling bulk materials from car to wagon or stock pile, or vice versa.

A great advantage of using the scoop conveyor to

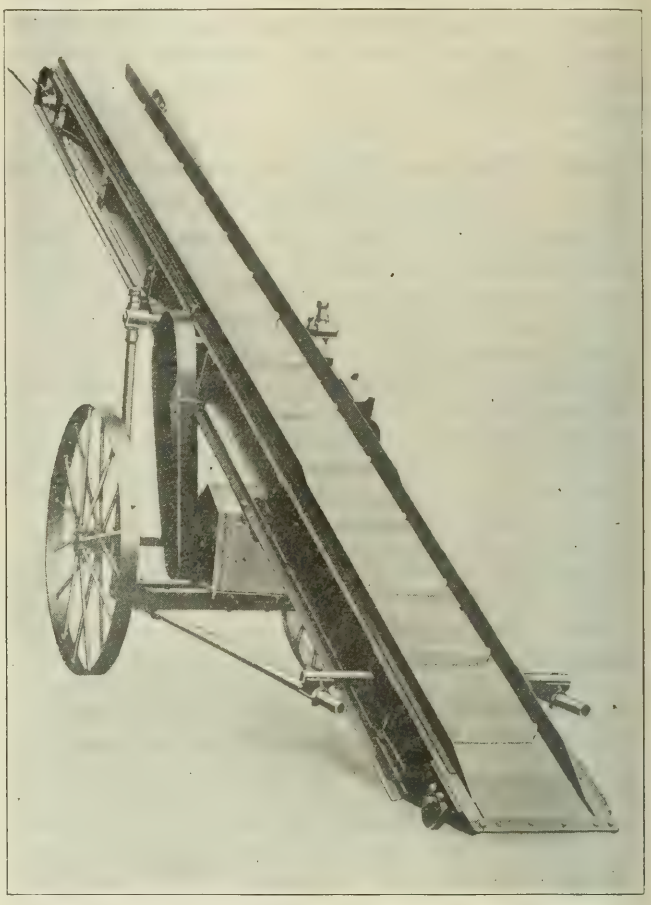


FIG. 1. SCOOP CONVEYOR FITTED WITH HIGH-FLIGHT BELT

unload hopper-bottom cars is the fact that no track hopper or pit is necessary. This makes it possible to unload cars at any point along the track. To unload a car, the feed end of the machine is placed near or under the car hopper, which is then released and the belt on the conveyor carries the material away as fast as it flows through the hopper opening.

FIG. 2. UNLOADING COAL A DISTANCE OF 150 FT. WITH FIVE SCOOP CONVEYORS

An interesting application for storing coal is shown in Fig. 2, illustrating five individual machines electrically driven being used to unload coal from hopper-bottom cars direct to storage pile. This provides a convenient, efficient and flexible arrangement. The first

FIG. 3. LOADING COAL HOPPER ON A HUNT ELECTRIC STORAGE BATTERY TRUCK WITH A SCOOP CONVEYOR

machine is practically self-feeding from the hopper doors of the car, and the four others may be swung around at any angle to cover a wide storage area, and can be operated by one or two men. They can also be used to reverse the operation and convey the coal direct from storage pile into boiler room, or singly to load as shown in Fig. 3.

Synopsis of Recent Chemical and Metallurgical Literature

The Solubility of Gold in Cyanide Solutions.—A paper on this subject, by A. H. WHITE, was published in the *Journal* of the Chemical, Metallurgical and Mining Society of South Africa for July, 1919, of which the following is an abstract:

The relative rate of solubility of gold and zinc by cyanide solution is proportional to their equivalent weights; thus

$$2Au : Zn = 394.4 : 65.37 = 6.03$$

Maclaurin has also found the relative rate of solubility of Au and Ag is proportional to their atomic weights.

The speed of the reaction depends entirely upon the rate of diffusion of the cyanide and oxygen in the solution in practice, of which the latter is the more important. The final effect of the reaction is given by the equation

$$2Au + 4KCN + O + H_2O = 2KAu(CN)_2 + 2KOH$$

394.4	260.44	16.0
1.000	0.6603	0.04057
1.5145	1.000	0.06144
24.648	16.276	1.000

Therefore 10 mg. oxygen per liter is equivalent to 0.0163 per cent KCN, 7 mg. to 0.0114 per cent KCN and 6 mg. equivalent to 0.0098 per cent KCN in solution. Since the average concentration in this district is 6 mg. of oxygen per liter, other things being equal, there is no advantage in maintaining the cyanide strength of the working solution in excess of 0.01 per cent KCN. It was found by experiment, however, that with about 6 mg. of oxygen per liter, the greatest speed of the reaction was with solutions containing between 0.02 and 0.03 per cent of KCN; sodium cyanide of equivalent strength being used, and the gold being free from electrolytic contact. Maclaurin found the maximum speed to take place at 0.25 per cent KCN; these results are only one-tenth this strength, but are confirmed by the fact that a similar degree of concentration, namely, 0.02 to 0.03 per cent, was found to give maximum speed of reaction for zinc, pure gold and for battery bullion in a solution made up with sodium zinc cyanide, the "total" cyanide strength being taken. There seems, therefore, to be no adequate reason for maintaining higher strengths of solution in contact with sand under treatment where the last portions to yield a profit have chiefly to be considered, and these may well be assumed to be in contact with quartz only. Adequate oxygen concentration is always of an advantage, especially in case of working solutions where side reactions are effective competitors for this oxygen.

The paper contains details of the experiments from which these deductions are drawn, together with tables and curves showing results.

Powdered Coal in the Chemical and Allied Industries.—The *Catalyst* of December contains the following abstract of an address delivered by W. H. FITCH before the Delaware Section, American Chemical Society.[1]

The steel and cement industries are the greatest users of powdered coal as a fuel. Altogether about 2,000,000 tons of powdered coal are used annually. In the steel industry open-hearth furnaces are the greatest users of coal, and there are about eighty-five furnaces thus equipped. About 75 to 80 per cent of the cement produced in the United States is made in the Lehigh Valley, and in this valley nearly all of the kilns are equipped to burn powdered coal. Most of these powdered coal plants have been put in during the last four years. Any kind of coal may be used, from lignites to anthracites. Even anthracites containing as high as 40 per cent non-combustible matter can be thus burned. Lignites must be dried to a water content of 4 or 5 per cent, bituminous coals and anthracites to less than 1 per cent. This drying is necessary to get economical grinding.

When powdered coal was first introduced everybody was afraid that great explosion risks would result therefrom. This has been demonstrated not to be the case, and the bugbear of those unfamiliar with powdered coal is now the ash problem. In regenerative furnaces this really constitutes a problem because the ash deposits in the brick checker-work. With a properly designed furnace, however, this is not serious. In a steam plant burning powdered coal about 10 per cent of the ash known to be in the coal deposits in a molten condition in the bottom of the combustion chamber. Beyond the bridge-wall a further small deposit is found, and in the rest of the setting no more than would be the case when firing coal with a mechanical stoker. The remainder, about 90 per cent, goes up the stack in a finely divided condition.

This is not surprising considering that the coal is ground so fine that 95 or 96 per cent goes through a 100-mesh sieve, 85 per cent through a 200-mesh sieve, and 72 to 75 per cent through a 300-mesh sieve. Powdered coal delivers from 25 to 30 per cent more of the heat value of the coal than gas producers and the installation and operating cost are about half as great as for gas producers. At the present time the total cost of delivering one ton of coal from the railroad

[1]The *Catalyst*, vol. 4, No. 10, p. 4, December, 1919.

siding, grinding it, and preparing it for burning in the pulverized form is about 60c.

Effect of Inclusions on Stress Distribution.—Considerable study has been given to stress distribution in non-uniform sections, notably to the effects of circular holes in tension members. Such variations were experimentally determined by Wilson and Gore using perforated rubber sheets, by Andrew McCance (*Trans.*, Inst. of Eng. and Shipbuilders in Scotland, vol. 62), plotting lines of equal hardness in permanently deformed metal, by E. G. Coker, *Trans.*, Inst. of Naval Architects, 1911; *Proc. Phys. Soc.*, London, vol. 25; *Proc.*, Inst. of Automobile Engineers, November, 1917, and *Trans.*, Inst. of Eng. and Shipbuilders in Scotland (December, 1919), studying interference figures by polarized light on transparent nitrocellulose sheets. McCance also suggests that since a piece is cooled when tension is applied, modern pyrometry, capable of measuring accurately within 0.001 deg., could be used to map lines of equal stress. C. E. Inglis has worked out a purely mathematical solution for both circular and elliptical holes in plates of infinite width (*Trans.*, Inst. of Naval Architects, 1913).

These researches show the surprising result that the dimunition of the section of a bar by a center hole is accompanied by a dimunition of stress at the outer edge of the perforated bar, owing to the great concentration of stress at the boundary of the hole. Stress at the latter point varies widely, from a value practically equal to 3 times the average on the transverse diameter, diminishing to zero at 60 deg. and to a maximum compression at the axial diameter. Intensity of these stresses at the inner edge of the hole is independent of the size of the hole, and the area surrounding subjected to higher stresses than the average is shaped like a two-bladed propeller, with a greatest width extending at right angles to the direction of stress of about 4 times the diameter of the hole.

McCance, in discussing Coker's latest paper in the *Transactions* of the Institution of Engineers and Shipbuilders in Scotland, December, 1919, points out the metallurgical applications of these results. Steel, no matter how well made, always containes non-metallic inclusions, and it has been found by experience that when fracture takes place its path nearly always favors segregated areas. But so long as the impurities are small and uniformly distributed, they do not seem to affect the steel, but when they are large or in clusters or segregates, they are dangerous, causing test pieces to break with low contraction and elongation. Apparently, if the particles are separated from one another by more than four times their diameter, the zones of overstrain caused by their presence (internal notching) do not overlap, and are consequently not so objectionable as when closer together, when their stress effects are mutually superimposed. If close enough, the stress in metal separating them may approach six times the average, and easily pass its elastic limit or ultimate strength. The larger the size of each particle, the greater the chance that another will be found enclosed within the overstressed boundary. Such ideas explain well the fact often encountered that when examining steel, cracks appear between two very small inclusions close together, but nearby single ones much larger have no cracks in their vicinity.

Recent Chemical and Metallurgical Patents

Complete specifications of any United States patents may be obtained by remitting 10c. each to the Commissioner of Patents, Washington, D. C.

Process of Treating Copper Ores by Lixiviation With SO_2 Solution.—Niels C. Christensen of Salt Lake City improves the process for the extraction of copper from ores by lixiviation with a sulphur dioxide solution. The leaching solution is kept free from sulphates by the exclusion of air and the formation of copper sulphates is prevented during the leaching and subsequent operations by the addition of metallic copper. Copper is recovered from solution by boiling off SO_2, this latter being used again. The accumulation of iron in the mill solution is prevented by the addition of lime or limestone. (1,316,351; Sept. 16, 1919; assigned to the Metallurgic Improvement Corp.)

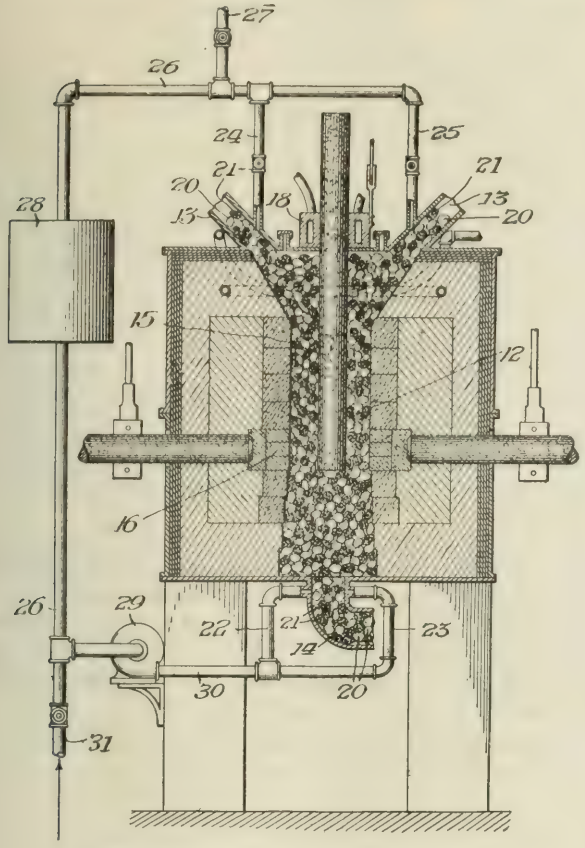
Tungsten Crucible.—Frederick G. Keyes of Hoboken, N. J., produces a tungsten crucible as follows: A form in the shape of a crucible is made by molding pure tungsten powder (sometimes mixed with ½ per cent NiO or with 20 per cent MoO). This form is filled with W_2O_5 or WO_2 and heated in a resistor furnace. This furnace is provided with a means of introducing carbon monoxide. As the tungsten oxides melt they are absorbed by the tungsten powder crucible form and then are reduced by the CO to metal. A homogeneous vessel of pure tungsten results. (1,318,452; Oct. 14, 1919; assigned to the Cooper Hewitt Electric Co.)

Ferro-Alloys.—Two patents have been issued to the estate of the late J. E. Johnson, Jr., on methods of producing ferro-alloys. In the first it is proposed to charge a high-temperature furnace with the usual ingredients for making ferrosilicon, with the exception that a feldspathic mineral is used as the source of silicon. At the high temperature needed to reduce the silica, the feldspar is decomposed and volatile alkaline metals driven off as oxides or carbonates, practically free from mineral acids and easily purified into salts of much value chemically. The fuel on heat consumption of the furnace is not materially greater than when using quartzite in the mix. In the second it is noted that low-carbon alloys can be made in ordinary furnaces (preferably a small blast furnace with enriched oxygen blast) if sufficient temperature is produced to reduce a considerable quantity of silicon from the charge. It appears that silicon has the important quality of excluding carbon from the alloys to a progressive extent as its quantity is increased. This undesirable silicon is then removed on tapping the alloy from the furnace by mixing with a molten reagent, made of iron oxide, lime and a little fluorspar. Silicon then replaces the iron in the reagent, and is fluxed as a lime silicate. (1,318,763 and 1,318,764; Oct. 14, 1919.)

Polyphase Electric Furnace.—Mark Shoeld of Chicago, Ill., provides for the uniform distribution of current flow in polyphase electric furnaces and therefore obtains uniform distribution of heat throughout the material to be treated. This is accomplished by mixing the material in the form of briquets with infusible heat-conducting resistor-elements of a

greater specific conductivity than the briquets. The current tends to flow through the resistor-elements, the material thereby being heated by conduction preventing the fusion of this material. The spacing of the electrodes and their distance from the furnace are important. (1,317,328; Sept. 30, 1919.)

This principle is applied in furnace shown in the illustration. In case aluminum nitride is to be produced the briquets 20 are composed of comminuted carbon, alumina and a suitable binder. The resistor-elements 21 may be composed of carbon. These are fed through chute 13, pass through furnace chamber 12 and are discharged at 14. The furnace has a central electrode 15 and a ring electrode 16. Nitrogen gas is caused to flow up through the furnace charge entering through pipes 22 and 23. This cool gas reduces the temperature of the treated charge and is itself heated, the hot gases after passing the heating zone pass through the incoming charge, heat being transferred to the charge from the gases which pass out through pipes 24 and 25. This gas may be carried by pipe 26 to the scrubber 28 and thence through blower 29 and pipe 30, completing the circuit, or a portion of the gas may be exhausted through pipe 27, in which case the supply is made up by the admission of gas through pipe 31. (1,317,327; Sept. 30, 1919. Both patents assigned to the Armour Fertilizer Works of Chicago, Ill.)



POLYPHASE ELECTRIC FURNACE

Removing Scale From Steel.—QUINTIN MARINS of Hendon, England, proposes the use of 25 deg. Bé. solution of alkaline sulphates and fluids, in proportions of 3 to 1. A carbon or lead anode, a current density of 20 amperes per sq.ft., and a temperature of 75 deg. C. are recommended. (1,324,317; Dec. 9, 1919.)

Book Reviews

CREATIVE CHEMISTRY. By *Edwin E. Slosson, Ph.D.* With an Introduction by Julius Stieglitz. 311 pp., illustrated. New York: The Century Co.

This is an excellent book on popular chemistry, designed to explain the application of the science to industry and daily life to the lay public. Although made up in chief part from a series of papers that appeared in the *Independent*, of which Dr. Slosson is literary editor, it is carefully planned and well put together. It is also richly illustrated. The text is by a man who writes with great ease and experience in the art of expression, and it makes pleasant reading to that part of the public that does not require tam-tams for its ragtime thought. The chapters, which number fourteen, consist of a short historical introduction, Nitrogen, Feeding the Soil, Coal-Tar Colors, Synthetic Perfumes and Flavors, Cellulose, Synthetic Plastics, The Race for Rubber, The Rival Sugars, What Comes From Corn, Solidified Sunshine (referring more particularly to vegetable oils and fats), Fighting With Fumes (or Gas Warfare), Products of the Electric Furnace, and Metals Old and New. These are followed by a well-selected bibliography for extended reading arranged according to subjects, and a good index. Of course, every subject treated is important enough to cover many volumes, but it is fair to say that Dr. Slosson has crowded an unusual amount of information into each chapter. ELLWOOD HENDRICK.

QUANTITATIVE ANALYSIS BY ELECTROLYSIS. By *Alexander Classen.* Revised, rearranged and enlarged English edition by William T. Hall. xiv + 346 pages. New York: John Wiley & Sons, Inc.

The revision and enlargement of this well-known book is chiefly in the introduction, which comprises about a third of the volume. The application of theory to the procedure in analytical methods tends to clarify the details in the mind of the student. A thorough comprehension of the principles and the application of the electronic theory is therefore essential to the successful use of electrolytic methods of analysis. The discussion in the introduction is well presented from this point of view. The brief historical review of the development of the science of electrochemical analysis is more extensive than in the previous edition. The remainder of the book has been rearranged, the sequence in which the determinations are discussed constituting a more logical presentation of the subject matter. Data consisting of the atomic weight, electrochemical equivalent, electrolytic potential and the overvoltage of hydrogen are given under each element. The revision has added to the value of the book and is sufficient to warrant the presentation of the new edition. L. W. CHAPMAN.

PROBLEMS OF LABOR AND INDUSTRY IN GREAT BRITAIN, FRANCE AND ITALY. 406 pages. A report of the European Commission of the National Industrial Conference Board, 15 Beacon St., Boston, Mass.

This report by a special commission of industrialists is the result of first-hand observation of conditions in Great Britain, France and Italy during the period immediately following the armistice. The report was prepared in the belief that it would be of assistance to American industry in solving its own problems of industrial readjustment. The report includes investigations into the efficiency of production and methods of stimulating the interest of the worker in increased output; the role of management in its relation to capital and labor; types of organizations of employers and employees; the development of unionism in Great Britain and the attitude of British employers toward it; the system of shop stewards and works committees; the 8-hr. day and the minimum wage; unemployment and housing; types of co-operative schemes and examples of welfare work; a review of the political labor situation in European countries and schemes for nationalizing various British

industries. The commission summarizes its findings in twelve closely printed pages. The widespread discontent among the laboring classes is ascribed mainly to the long strain of the war and the industrial and economic disturbances incident thereto. Fallacious economic teachings, particularly with respect to restricted output, are held responsible for the low efficiency of production. Trade unionism has increased greatly in recent years in all countries visited, but especially in Great Britain, where there is a tendency toward consolidation and unity. This has resulted in forcing British employers to organize among themselves for dealing with trade and labor problems. Shop stewards are seen as a menace, but works committees are considered to be a fair means for bringing employers and workmen together. The movement to establish an 8-hr. day and minimum wage has progressed rapidly in all the countries visited and laws have been passed establishing these principles. The commission found the labor situation "shot through and through with political influence," labor organizations and the socialist parties overlapping to a great extent in membership. Attention was directed to the fact that there has been no organized effort to combat the effect of teachings of socialism, and the commission is of the opinion that "some elementary teaching is needed to show that capital is as essential to industry as labor, and that capital is the one factor of production which assumes practically all the risks and uncertainty and loss."

H. C. PARMELEE.

Personal

Dr. P. G. AGNEW, physicist in the electrical division of the Bureau of Standards, has resigned to become secretary of the American Engineering Standards Committee, with headquarters at the Engineering Societies Building, 29 West 39th St., New York City.

H. C. BARNES has joined the Allegheny Gear Works at Pittsburgh as superintendent of laboratory and metallurgical work. Mr. Barnes is a technical graduate, having been for more than ten years in complete charge of heat treatment for one of the largest gear manufacturers and supervising similar work at one of the large steel mills.

Dr. WALTER H. EDDY, of Teachers College, Columbia University, associate in physiological chemistry, has been appointed assistant professor of physiological chemistry. Dr. Eddy has recently returned from France, where he served fifteen months with the A. E. F. as major in the Sanitary Corps.

H. LIPSON HANCOCK, general manager, Wallaroo & Moonta Mining & Smelting Co., South Australia, is making a visit to the principal copper mining and smelting centers of the United States. He expects to sail from San Francisco some time in March.

ARTHUR G. HENRY, metallurgist for the Illinois Tool Works and secretary of the American Steel Treaters' Society, has resigned to become Chicago representative of the Vanadium Alloys Steel Co.

IRVING H. JONES is now associated with Joseph R. Ryerson & Son in the machinery department, specializing in sales engineering work in the Chicago district.

ROBERT M. KEENEY, consulting engineer of the York Ferro-Alloys Co., will be at York, Pa., for several weeks.

Dr. ARTHUR LACHMAN, a well-known chemist of San Francisco, formerly professor in the University of Oregon, was last seen on the street at noon on Dec. 11, 1919. Since then his family and friends have been unable to obtain any clue or any trace of his whereabouts. It seems probable that he had an attack of amnesia with loss of identity and wandered away. Anyone having information in regard to him is requested to communicate with his family or with Dr. Felix Langfeld, 272 Post St., San Francisco, Cal.

P. E. LANDOLT has been appointed manager of the commercial department of the Research Corp., New York City. Mr. Landolt has been connected with the corporation from its inception.

D. J. LEWIS, JR., formerly with and secretary of W. J. Wayte, Inc., has severed his connection with that company and is now sales agent for the Cresson-Morris Co. and the Kestner Evaporator Co., with headquarters at 277 Broadway, New York City.

W. A. LEDDELL has been appointed manager of the engineering department of the Mine & Smelter Supply Co. with headquarters at Denver, Col.

R. S. MCBRIDE, who has been engineer-chemist of the National Bureau of Standards, resigned on Jan. 15 to join the McGraw-Hill Co. staff in Washington, D. C., as an engineering representative. Mr. McBride was educated at the University of Minnesota, where he received the degree of B.S. in 1908, and at the University of Wisconsin, where he did one year's graduate work and obtained the M.A. degree in 1909. He has been in charge of the gas engineering investigations of the Bureau of Standards for over ten years, specializing in problems of gas supply, gas testing, fuel utilization, byproduct recovery, and the related public utility work of the Bureau. Mr. McBride has been the author or has directed the preparation of over fifty printed articles on various parts of the work as well as had charge of the field studies which have resulted in the preparation of about the same number of engineering and chemical reports not published thus far. As department editor of the *Journal of Industrial and Engineering Chemistry*, a contributor in charge of the Patents and Abstracts sections of the *Gas Record*, and as grand editor of his national fraternity quarterly, the *Hexagon* of Alpha Chi Sigma, Mr. McBride has also had considerable editorial experience.

Dr. FRITZ PANETH, director of the chemical department of the German technical high schools at Prague, has been appointed professor of chemistry at the University of Hamburg, Germany.

L. DUANE SIMPKINS has severed his connection with the Peters Cartridge Co. as metallurgist and chemist, to accept the position of metallurgist with the National Lead Co., Brooklyn, N. Y., in the research laboratory.

LEWIS B. SKINNER, consulting engineer, of Denver, Col., is in New York on business.

PAUL C. SKINNER has been recently made general manager of the General Chemical Co.'s plant at Denver, Col. Mr. Skinner, who has been for years connected with the plant under management of the Western Chemical Co., has worked up through all the departments of the business to the present position under the new management. He has been spending considerable time at the Chicago headquarters recently making arrangements for extensions of plant and business.

Dr. S. A. SOCHOCKY, general technical director of the Radium Luminous Materials Co. of New York, was recently elected president of the company.

WILLIAM A. THOMAS has resigned as president of the Brier Hill Steel Co., Youngstown, Ohio, having been president since 1912. JAMES H. GROSE, formerly general superintendent in the Youngstown district for the Carnegie Steel Co., has been elected to succeed Mr. Thomas.

Dr. WILLIAM H. WALKER, head of the department of applied chemistry at the Massachusetts Institute of Technology, Cambridge, Mass., has been appointed head of the new division of industrial co-operation and research.

Obituary

E. FRED WOOD, formerly vice-president of the International Nickel Co., died suddenly at New York City on Jan. 5, in the sixty-second year of his age. Mr. Wood was born in Milwaukee on Aug. 28, 1858. He was educated in the public schools of his native city and later entered the University of Michigan, where he was a brilliant student and was graduated with distinction. After leaving college Mr. Wood devoted himself assiduously to the study of metallurgy and in connection with his studies made extensive trips through the various mining camps of the

West and lived for a year at Leadville and in other mining towns, where he pursued his studies and obtained his practical experience. He later entered the employ of the Carnegie Steel Co. and rapidly rose to the position of assistant general superintendent of the Homestead plant, which position he filled for a number of years. During the period of the big strike at the plant, when Mr. Frick was shot, Mr. Wood was in entire charge of the plant. He was looked upon by Mr. Carnegie and his associates as one of the valuable men of the organization and was one of the so-called "Carnegie Veteran Associates."

Because of the great reputation that he had achieved he was invited to join the International Nickel Co. upon its organization, becoming first vice-president of the company and a member of the board of directors and of its executive committee, and he was an important factor in developing the mining, smelting and refining business of the company, so that from a small and unimportant undertaking it developed into the largest business of its kind in the world.

When the United States entered the World War, Mr. Wood resigned his official connection with the International Nickel Co. to devote himself to public work, and became a member of the Committee on Production of the War Industries Board, of which committee Samuel Vauclain, president of the Baltimore Locomotive Works, was chairman. Mr. Wood served continuously on this board during the entire period of the war, without compensation. His work on this board was conspicuously fine and of inestimable value and won the admiration and commendation of those who were brought into contact with it. It was the kind of work for which his talents were especially fitted and in which he took particular interest.

Mr. Wood was a man of great learning in his profession and of a wonderful memory, which enabled him to have on tap, ready for use, the result of his many years of study, observation and experience. He was keenly interested in travelling; he visited almost every country on the globe and had the unique distinction of having travelled around the world twice in one year. He was a member of the University of Michigan Club, the Automobile Club, the New York Athletic Club, the Society for Electrochemical Engineers and of the Railroad Club.

Current Market Reports

The Non-Ferrous Metal Market

New York, Jan. 26, 1920—Tin advanced ½c. in the last week. The copper market has been quiet, with price unchanged. The other metals have changed slightly in price in a very few instances.

	Cents per Lb.
Copper, electrolytic	19.50
Aluminum, 98 to 99 per cent	32 @ 33
Antimony, wholesale lots	11.00
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	63.25
Lead, New York, spot	8.62½
Lead, E. St. Louis, spot	8.30
Zinc, spot, New York	9.52½
Zinc, spot, E. St. Louis	9.20
Silver (Dollars per oz.)	1.31⅞

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	27.50
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	33.50
Seamless bronze tubing	34.50
Seamless brass tubing	30.50

RARER METALS

Cadmium	lb.	$1.50 @ 2.50
Cobalt	lb.	1.90
Platinum	oz.	150.00
Iridium	oz.	250 00
Palladium	oz.	150 00
Mercury .75 lb.		93.00

SCRAP METALS

	Cents Per Lb.
Aluminum, cast scrap	23½ @ 24½
Aluminum, sheet scrap	22½ @ 23½
Aluminum clippings	25½ @ 27
Copper, heavy machinery comp.	14½ @ 14½
Copper, heavy and wire	13½ @ 14
Copper, light and bottoms	12½ @ 12½
Copper, heavy cut and crucible	15½ @ 16
Brass, heavy	7½ @ 8½
Brass, casting	10½ @ 10½
Brass, light	5½ @ 6½
No. 1 clean brass turnings	8½ @ 8½
No. 1 comp. turnings	12 @ 12½
Lead, tea	5½ @ 5½
Lead, heavy	6½ @ 7
Zinc, scrap	4½ @ 4½

The Iron and Steel Market

Pittsburgh, January 23, 1920.

Increasing production of steel, with concurrent increase in the anxiety of buyers to cover for forward deliveries, indicates that there is either a large increase in the actual consumption requirements, present and prospective, or a great increase in the nervousness of buyers. It is not always the case in the steel market that the anxiety of consumers to buy is in precise proportion to their requirements. Sometimes they buy less than they will need and sometimes they have bought more.

The unwillingness of many of the producers in the past few weeks to cover their customers, regular and occasional, has undoubtedly produced some of the anxiety now so apparent. In the case of a number of large producers this conservative policy in the matter of selling has been due to an unwillingness to sell at the March 21 or Industrial Board prices, to which the United States Steel Corporation steadfastly adheres, and at the same time an unwillingness to make formal and regular advances over that schedule. In many cases producers have promised to take care of regular customers' requirements in the second quarter, at prices to be named later, and thus the time has been rapidly approaching at which definite price action must be taken.

Predictions as to the Course of Prices

There are many predictions being made as to the course of prices named by the independents. One possibility, regarded almost everywhere as an unfortunate one, is that there will be a runaway market, prices advancing until the whole structure becomes topheavy, with the natural and inevitable outcome. A prediction that seems reasonable from several aspects is that the larger independents will advance prices of most commodities to the level that obtained between Dec. 12, 1918, when the post-armistice reductions were made, and March 21, 1919, when the Industrial Board reductions went into effect. The December reductions were $4 to $8 per net ton on most finished steel products, with no reductions at all on wire products, while the March reductions were $7 a net ton on all important rolled steel products, with $5 reduction on wire products, including nails, grooved skelp being reduced $5, while universal and sheared were reduced $7. The prediction mentioned, therefore, is that prices will go back to the level of January and February of last year, equivalent to an advance from present basis prices, largely nominal, averaging a little less than $7 a net ton. If this prediction as to finished steel is verified, however, it is unlikely that unfinished steel would advance only by the $5 a gross ton by which it was reduced in March. That would put sheet bars at $47, whereas it seems more probable that they will advance to about $50, and indeed some sales have lately been made to regular consumers at that figure. Sheet consumers, buying for the purpose of having the steel rolled into sheets under contract, would in some cases pay $55 or $60, and some business of this description has been done.

Operating Rates

It may be estimated that the steel mills as a whole are now operating at between 85 and 90 per cent, this comparing with a rate of about 80 per cent at the beginning of the month and an average of not over 60 per cent during the last three months of the old year. The most important restrictive influence now is transportation, this replacing

labor as the chief factor. In point of numbers labor supplies are now practically adequate at most plants. Efficiency and morale of men in employment have increased, but there is still some distance to travel in these respects.

Car shortages are experienced at many plants in the matter of shipping finished products, but not to an extent to cause material to back up against production. Shortages of cars in the Connellsville region for loading coke and at various mines shipping coal to byproduct ovens are a serious limiting factor, and while conditions have been improving somewhat in the past week, the demand for coke keeps well ahead of the supply. More pig iron is being made than at the beginning of the month, but there are still some idle furnaces, awaiting a coke supply, and a number of furnaces are operating with reduced blast pressures to conserve their coke supplies.

Prospects of Demand

There are very conflicting statements as to the prospects of demand for steel for building purposes. In some quarters it is insisted that, labor and material costs as they are, few investors will take hold at present, while in other quarters there are assertions that a very large amount of construction work is in immediate prospect. The requirements of ordinary manufacturing consumers have proved heavier than could be expected. A year ago there was no thought that demand for steel, as a whole, could be as heavy as it has been with the amount of new construction as small as in the past year, and with so little steel passing to the railroads, yet a relatively large quantity of steel has gone somewhere.

As to the railroads, much is being said as to the needs of the railroads, while little is being said, except by railroad officials, as to the ability of the roads to finance purchases, and what the railroad officials say is that they cannot finance purchases unless conditions are made distinctly favorable. The rail requirements are covered very largely either by actual purchases or by reservations, while as to other purchases there may be delays greater than have lately been expected. It is possible that many buyers of steel have deluded themselves in the expctation that the railroads will be heavier buyers in the next few months than will actually prove to be the case, and the course of events will bear careful scritiny from this viewpoint.

The Chemical Market

New York, January 23, 1920.

There has been no change in the general conditions of the market during the past week, prices remaining at the same level. Domestic consumers have not shown a tendency to invest in large stocks at present quotations, preferring instead to contract on future delivery. Manufacturers are sold ahead on contract, and several large factors in the chemical market say they will have nothing to offer until late in 1920.

Heavy Chemicals:—The demand on all grades of *alum* continues strong, but there has not been a large enough demand to warrant an increase in price. The market in *barium* products has been active, with an increase in quotation from $80@$85 per ton for barium chloride to $90@$100 per ton. The continued coal scarcity has hampered producers of *aqua ammonia,* which is being offered at 8¾c. per lb. on spot and 8½c. on contract in drums. *Caustic potash* is steady in demand, export business being about the same as last week, and quotations remain the same at 28@32c. per lb. The demand on *caustic soda* is still very heavy, especially for export. There was a shipment of 450 tons reported during the last week, but this lot about cleans out producers for the time being. The price on the above-mentioned shipment was $4.25 per cwt., but the price quoted by second hands, who at present control the market on this item, is $4.50 per cwt. and up, and it is the opinion of some that this item will reach 5c. per lb. shortly. *Sodium nitrite* continues steady in demand, and it is hoped that with the arrival of a large consignment to one of the manufacturers there will be a drop in this product, which at present is quoted at 15@17c. per lb. according to the quantity desired. There have been no new developments in the *alcohol* situation, demand on *ethyl* continuing heavy, while *methyl* is unobtainable. Dealers in the *wood* grade refuse to quote, there being none to be had on spot and contracts have been made so far ahead in some cases that the output will be taken up for several months to come. The scarcity in *formaldehyde,* reported last week, still prevails, this item being practically off the market at present. There has been no change in the producers' quotations of $12 per cwt. on *acetic acid,* glacial 99½ per cent, during the past week. *Oxalic,* crystals, remains firm at 31@35c. per lb. A bill is now before the House of Representatives to levy a tariff on this item of 5c. per lb. in order to restrict the price on this item.

Coal-Tar Products:—The market still continues scarce in supply, especially in raw materials, and prices are quoted at the same general level. Export inquiry has been heavy, with difficulty on the part of the producer in meeting this demand. *Aniline oil* and *salt* continue firm, prices holding from last week, 34@36c. per lb. on the former and 45@50c per lb. on the latter. *Toluol* is easier at 28c. per gal. in tanks and 29c. in drums, with a somewhat larger supply on hand. One large producer of H acid has stopped quotations on this item, as he is contracted up to June, with all available spot material in second hands.

Waxes:—This branch of the market during the past week has continued firm, any action in price being caused by an actual scarcity of spot material on hand. There has been a noticable stiffening in all lines of the paraffine grade, of ¼c. to ½c. on each item. Japan continued active at 19½@20c. per lb. for the usual requirements, but no large orders have been placed.

Flotation Oils:—Considerable activity in demand has been the feature of this market during the past week. A general increase in price of all items has been caused by an increased demand combined with a natural scarcity of crude materials. *Pine oil,* steam distilled, sp.gr. 0.930-0.940, jumped from $1.38 to $1.45 per gal., while pine tar oil, crude, sp.gr. 1.025-1.035, tank cars, f.o.b. Jacksonville, Fla., jumped from 35c. to 48c. per gal. *Crude turpentine,* in sympathy with the spirits and under heavy demand at present, has had a rise from $1.40 to $1.60 per gal.

Naval Stores:—Spirits of turpentine remains the center of attraction in this market, quotations remaining $1.97@ $2 per gal. There has been no relief in the London market, and demand still continues brisk, with a threatened upward price. The situation will be relieved only by the dropping out of the bullish element of the market. Demands, both export and domestic, have been heavy on the New York market for *turpentine* and *rosin,* Grade B, which is quoted at $19.50 per 280 lb.

Vegetable Oils:—Linseed Oil has shown a slight indication of coming back during the past week, though the amount of actual business recorded has been small. No immediate large demand is expected by dealers, but it is expected that the coming season will bring a larger demand by consumers than was placed last year. Most of the present output is used to fill contracts made last year for future deliveries. The quotation still remains $1.72 per gal. Stocks of *soya bean* and *peanut oil* are diminishing, while no large stocks of *cocoanut oil* are to be found on spot in the market. There has been a general strengthening during the past week in this market, prices remaining steady, but buyers are somewhat wary of existing prices.

St. Louis, January 21, 1920.

The good demand for heavy chemicals which has been manifested since the first of the year continues in St. Louis. The demand for *sulphuric acid,* which slumped last month, has stiffened in the last two weeks. There is very little spot buying; the reason being small stocks, not few inquiries. Contract buyers are having no trouble in filling their requirements, however. Local men look for this condition to continue on account of the absorption of surplus stocks. A slight rise in prices is predicted.

Sulphuric Acid:—The demand for this chemical is picking up due to the fact that conditions in the coal business are getting back to normal and there has been an easing up of the phosphate rock situation. It is almost back to normal at

present and as soon as operations in the oil fields are in full swing once more this chemical will be in heavy demand. Prices have started to rise now over what they were two weeks ago. The 60 deg. grade is quoted at $14@$15 a ton, where two weeks ago it was at $12@$14, according to quantity. The 66 deg. grade has gone from $18 to $20 a ton, though oleum is still quoted at $25 a ton, as it was two weeks ago.

Muriatic Acid:—There is a normal movement in this chemical, it having recovered from the slight slump it was in two weeks ago. There have been a number of inquiries and producers report several sales. It is quoted at $22 a ton for the 18 deg. grade.

Sodium Sulphate:—There is a fair inquiry for this chemical, though not many sales have been reported in the last week, none of them being over $20 and the average being $19.50.

Sodium Bisulphate:—The movement in this chemical is better than at the beginning of the month, though there has been no change in price. Several large contracts have been closed during the past week, all of them at the low price prevailing the first of the year, $2.50. On account of the fact that these large contracts will remove part of the supply from the market, producers look for the price to rise in the near future.

Nitric Acid:—There is little demand for this acid and the market remains at 10@10½c. per lb. for 38 deg.

Zinc Chloride:—There is a greatly increased demand for this, due to the fact that the manufacturers of creosoting oils have resumed operations in full swing. This may be attributed to the fact that when the railroads are turned back to the hands of the private owners there will be a big demand for railroad ties, many of the roads having been neglected in that respect by the Railroad Administration.

Zinc Oxide:—Advices have been received here that Eastern manufacturers have raised prices ½c. a lb. on bbl. shipments for all grades except the high-leaded zinc oxide, 20 and 30 grades, which have been raised ¾c. a lb. on bbl. shipments. No advances have been made yet by local makers. The demand is strong and many orders are on the books for immediate shipment and plants are working to their capacity to keep pace with the orders. It has been necessary during the past week to make advances in labor wages, and all things indicate prices will advance later on.

Phenol:—This is in very good demand for domestic consumption, practically all on the market being Government material, which a St. Louis chemical concern has contracted to market. In 15-ton lots, f.o.b. St. Louis, Philadelphia or New York, it is bringing 12c. per lb., with smaller quantities at slightly higher prices. There is a shortage of this item for export purposes.

Chicago, January 21, 1920.

Remarkable steadiness is shown in all lines this month, with the general tendency upward. Steady domestic demand, increasingly heavy exports of certain items and greater producing costs have combined to produce the present strong market, and the fact that many producers are under contract for their full output for some time will tend to prolong present conditions. A comment heard among manufacturers is that it seems impossible to procure as heavy production today as was the case in the past with the same plant and force of men, seeming to indicate that the lessened efficiency of labor, so often noted in other lines, is now felt in the production of chemicals.

Heavy Chemicals:—Exports of *granulated caustic soda* to Europe and the Orient continue heavy and the price remains firm as last quoted—$4.50 per cwt., in carloads, f.o.b. works. The solid is firm at $4. So much of the future output of caustic is under contract at these figures that spot stock buyers will probably be asked even more for some months to come. *Bleaching powder* and *soda ash* are also in heavy demand for export, considerable quantities being put under contract for shipment to the Far East. *Bleaching powder* in carlots is bringing $2.50@$2.60 per cwt. for immediate shipment, with producers showing no anxiety for long-term contracts. *Soda ash* is worth $1.75 per cwt. on contracts for future delivery, and $2.10 is asked in cars f.o.b. works for spot shipment. *Sodium bicarbonate* is also in good tone, with $2.75 per cwt. asked for spot delivery in less than carlots, $2.40 in cars, f.o.b. factory. *Niter cake* (sodium bisulphate) is in fair demand at $7@$7.50 per ton in large quantities.

Sodium bichromate, which was completely out of hand in the local market a month ago, is back again at 20c. in bbl. lots and indications are that this figure will hold good for some time. *Formaldehyde* presents the most spectacular advance of the month. It is much in demand, is very scarce, and 50c. per lb. is asked for the limited quantities available. *Alcohol*, also, is in good demand, with *ethyl* quoted in less than carloads at from $5.30@$5.50 per gal. *Methyl* is even stronger, available spots going freely at $1.80 in reasonable quantities. *Oxalic acid*, under heavy demand from the dyestuffs, manufacturers, is high and short in supply, 40c. a lb. now being quoted in barrels.

Roll sulphur (brimstone) has developed a very strong tone, price from factory being about $3.80 per cwt. in cars. This item is quoted by jobbers as high as 5c. per lb. in bbl. lots. Acids, except for oxalic as mentioned above, remain quiet, the demand still being somewhat below normal, with 66 deg. sulphuric quoted at $20 a ton in quantities, and 20 deg. hydrochloric (muriatic) at $2.25 per cwt. in less than carloads. With the gradual straightening out of the steel industry the acid market should show considerably more strength, as with consumption in full swing manufacturers will be hard pressed to supply the needed quantity.

Coal-Tar Products:—Very severe shortage of *benzol* has forced the price even higher than it was at the end of the coal strike, the current price being 33c. *Toluol*, being in slightly better supply, is selling at 27c. in tanks, with deliveries fairly prompt. Continued short supply of *anilines* has forced the *oil* up to 35c. and *salts* to 45c. These prices are for small quantities only, no large supplies being available. Very little business for future delivery is reported.

Benzoic acid is slightly firmer, 95c. being current quotation for U.S.P. and 78c. for technical in wholesale quantities. *Picric acid* shows no change from the former quotation of 20c., but excess stocks are dwindling and an advance is looked forward to shortly. *Salicylic*, under moderate demand, remains at 44c. per lb. for the technical grade.

Vegetable Oils:—This entire line shows considerable strength, except in *corn oil*, which is being freely offered at 17½c. in sellers' tanks, and *cottonseed oil*, which shows only fair demand at 19½c. for crude and 24c. for prime summer yellow in barrels. *Cocoanut oil* is in excellent demand, 18½c. per lb. ruling for Manila grade in sellers' tanks, f.o.b. Pacific coast. Similar grade in barrels is bringing 19½c. in Chicago. *Soya bean oil* is also much wanted, the market being strong at 17½c. in barrels.

Flotation Oils; Naval Stores:—Having thoroughly recovered from the slackening in demand occasioned by the fuel strike, *pine tar products* are developing such heavy demand as to guarantee a strong market for some time. Distilled pine tar oil, .933 pure, is easily sold at the current quotation of $1.50 and a rapid increase in price is expected. The *destructively distilled* grade carries the same price and is even harder to get. *Turpentine*, in cars, is quoted at $2 @$2.05 per gal. f.o.b. Chicago, and the jobbers' price in barrels is $2.16. Actual needs in the various industries are in excess of supply and it is hard to tell how high the market may climb before the new crop comes in March.

Rosin, likewise, is scarce and high priced. It is noted that the first exportation of rosin to Germany since 1914 occurred last week, when 1,500 bbl. left Savannah, and inquiries are being received in the local markets from Bavarian consumers. Ruling prices are, for F grade, $20.20 per cwt. in barrels, delivered, and for WW grade, $24.50@$25. Fluctuation is so rapid that these quotations may be considered nominal.

Fertilizers:—With stocks still suffering from the depletion which occurred during the fuel shortage and with both domestic and foreign demand strong, prices are on the up grade. Ground blood at $7.85 and unground blood at $7.65 have scored higher than at any time last year.

Tankage is also in strong demand, high-grade ground being quoted at $7.50 and bone meal, raw, is now sold at $44.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	..... –	$0.60 – $0.65

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.34 —	.36
Aniline oil, drums extra	lb.	.34 —	.36
Aniline salts	lb.	.45 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.25 —	1.30
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech.	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.52
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U.S.P., in drums (100 lb.)	lb.	.18 —	.....
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.75 —	.80
Cresylic acid, 95-97%, dark, in drums	gal.	.72 —	.75
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline	lb.	.90 —	1.00
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.58 —	.75
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.27 —	.30
Ortho-amidophenol	lb.	3.00 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.90 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.15 —	.18
Paranitraniline	lb.	1.00 —	1.20
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.50 —	4.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.60 —	1.00
Phenol, U.S.P., drums (dest.), (240 lb.)	lb.	.12¾ —	.19
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.55 —	.60
Salicylic acid, U.S.P.	lb.	.42 —	.50
Salol	lb.	.90 —	.95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.22 —	.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30

Toluidine	lb.	$1.70 —	$2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.45
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white, pure	lb.	.63 —	.68
Carnauba, No. 1	lb.	.80 —	.88
Carnauba, No. 2, regular	lb.	.65 —	.78
Carnauba, No. 3, North Country	lb.	.46 —	.48
Japan	lb.	.18½ —	.20
Paraffine waxes, crude match wax(white) 105-110 m.p.	lb.	.06 —	.07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.07
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½ —	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.14
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp.gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots:

Rosin B-D, bbl.	280 lb.	$17.00 —	$17.50
Rosin E-I	280 lb.	17.85 —	18.40
Rosin K-N	280 lb.	19.75 —	22.50
Rosin W. G.-W. W.	280 lb.	22.50 —	24.25
Wood rosin, bbl.	280 lb.	17.00 —	17.50
Spirits of turpentine	gal.	.... —	1.97
Wood turpentine, steam dist.	gal.	.... —	1.70
Wood turpentine, dest. dist.	gal.	1.64 —	....
Pine tar pitch, bbl.	200 lb.	8.25 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	14.75
Retort tar, bbl (500 lb.)	bbl.	15.00 —	15.25
Rosin oil, first run	gal.	.... —	.91
Rosin oil, second run	gal.	.93 —	.94
Rosin oil, third run	gal.	1.10 —	1.12
Rosin oil, fourth run	gal.	.... —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naptha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.47½ —	$0.48½
Upriver coarse	lb.	.34 —	.35
Upriver caucho ball	lb.	.33½ —	.34½
Plantation—First latex crepe	lb.	.52 —	.54½
Ribbed smoked sheets	lb.	.51¾ —	....
Brown crepe, thin, clean	lb.	.48 —	.48½
Amber crepe No. 1	lb.	.53 —	....

Oils

VEGETABLE

The following prices are f.o.b., New York, for carload lots:

Castor oil, No. 3, in bbls.	lb.	$0.18 —	$0.19
Castor oil, AA, in bbls.	lb.	.21 —	.23
China wood oil, in bbls.	lb.	.23¾ —	.24½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.20 —	.20¾
Cocoanut oil, Cochin grade, in bbls.	lb.	.20½ —	.23
Corn oil, crude, in bbls.	lb.	.19 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19 —	.20
Cottonseed oil, summer yellow	lb.	.22 —	.27
Cottonseed oil, winter yellow	lb.	.24½ —	.25½
Linseed oil, raw, car lots	gal.	1.77 —	1.87
Linseed oil, raw, tank cars	gal.	1.70 —	1.80
Linseed oil, boiled, car lots	gal.	1.75 —	1.80
Olive oil, commercial	gal.	2.50 —	2.60
Palm, Lagos	lb.	.17 —	.18
Palm, bright red	lb.	.16½ —	.17½
Palm, Niger	lb.	.16 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½ —	.24
Peanut oil, refined, in bbls.	lb.	.27 —	.28
Rapeseed oil, refined in bbls.	gal.	1.45 —	1.68
Rapeseed oil, blown, in bbls.	gal.	1.60 —	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19 —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17¾ —	.20

FISH

Winter pressed Menhaden	gal.	$1.20 —	....
Yellow bleached Menhaden	gal.	1.23 —	....
White bleached Menhaden	gal.	1.25 —	....
Blown Menhaden	gal.	1.26 —	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.03½ —	.04½
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	.16 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	$ .04½ —	$ .06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	13.50 —	18.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30.00 —	35.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35.00 —	45.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, TN	lb.	1.10 —	1.15
Shellac, D. C.	lb.	.... —	....
Shellac, V. S. O.	lb.	.... —	....
Shellac, Diamond I.	lb.	.... —	....
Shellac, orange, fine	lb.	1.25 —	....
Shellac, orange, superfine	lb.	1.20 —	1.30
Shellac, A. C. garnet	lb.	1.10 —	....
Shellac, bleached, bone dry	lb.	1.35 —	....
Shellac, bleached, fresh ground	lb.	1.10 —	1.15
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	80-90 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	35-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	30-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-90 at Chester, Penn.
Silica brick	1,000	41-45 at Mt. Union, Penn.

Ferro-Alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome per lb. of Cr contained, 6-8% carbon	lb.	.20 —	.40
Ferro-chrome per lb. of Cr contained, 2-4% carbon	lb.	.21 —	.50
Ferro-manganese, 70-80% Mn	gross ton	140.00 —	150.00
Spiegeleisen, 16-20% Mn	gross ton	40.00 —	50.00
Ferro-molybdenum, per lb. of Mo	lb.	3.00 —	3.50
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1.25 —	1.40
Ferro-uranium, 35-50% of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	5.50 —	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	7.50
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	6.50
Petroleum coke, refinery, Atlantic seaboard	net ton	..... —	14.00
Fluorspar, gravel, f.o.b. mines	net ton	..... —	25.00
Manganese ore, 45% Mn and over	unit	.50 —	.75
Manganese ore, chemical (MnO_2)	gross ton	60.00 —	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	9.00 —	15.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	7.50 —	10.00
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	.....
Rutile, 95% TiO_2	lb.	.11 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	.....
Monazite, per unit of ThO_2	unit	42.00 —	.....

* Government prices.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.80
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	16.00
Yellow pine, 3x4 to 8x8, 20 ft. and under	M.	48.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago	M.	50.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis	M.	40.00
Roofings, tar felt (14 lb. per 100 sq. ft.)	ton	70.00
Roofings, tar pitch (in 400-lb. bbl.) carlots	ton	21.00
Roofings, asphalt pitch carlots	ton	34.00
Roofings, asphalt felt carlots	ton	63.00
Roofings, slate-surfaced, per roll of 108 sq. ft. carlots		2.25
Roofings, slate-finished shingles, 100 sq. ft. carlots		6.00
Linseed oil, raw in barrels	gal.	1.75
Linseed oil, 5 gal. cans	gal.	1.90
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.15½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13½
White lead, dry and in oil, 5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ¾-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

CHANDLER—The Bd. Educ. will receive bids until Feb. 14 for the construction of a high school, including a science building. Estimated cost, $150,000. Allison & Allison, 1405 Hibernian Bldg., Los Angeles, Cal., archts.

California

EL SEGUNDO—The Standard Oil Co., 200 Bush St., San Francisco, has awarded the contract for the construction of additions and improvements to its refinery, to the Foundation Co., Holbrook Bldg., San Francisco. Estimated cost, $2,000,000.

Connecticut

WINDSOR—The General Electric Co., Lynn, Mass., will soon award the contract for the construction of a 3-story, 67x200-ft. manufacturing building.

Maryland

BALTIMORE—The Mutual Chemical Co. of America, Block and Wills Sts., has awarded the contract for the construction of a 2-story, 100x200-ft. addition to its chemical plant at 1348 Block St., to Morrow Bros., 1201 Fidelity Bldg. Estimated cost, $60,000.

Massachusetts

PITTSFIELD—The General Electric Co., Morningside, will build a 1-story, 80x400-ft. enameling building addition. Work will be done by day labor.

WEST MEDFORD (Boston P. O.)—The Warner & Childs Paper Co. has awarded the contract for the construction of a 4-story, 100x225-ft. factory on Boston Ave., to W. M. Bailey Co., 88 Broad St., Boston.

Michigan

DETROIT—The Butt Welding & Mfg. Co., Bellevue and Warren Aves., plans to build a 20x100-ft. building. F. W. Biederman, mgr.

DETROIT—The Detroit Grey Iron Fdry. Co., Wight St., has awarded the contract for the construction of a 2-story, 135x150-ft. foundry, to J. L. Kolley, 3563 Jefferson Ave.

GRAND RAPIDS—The Bd. Educ. plans to construct a 3-story, 225x250-ft. school, to be known as the North Junior High School, on Plainfield Ave. Chemical laboratory equipment will be installed in same. H. H. Turner, 234 Division Ave., N., archt.

Minnesota

MESABA—D. C. Jackling and Hayden & Stone, 25 Broad St., New York City, plan to construct 10 concentration plants on various points on Mesaba Range. The first unit will cost $3,000,000, ultimate cost $30,000,000. Dwight E. Woodbridge and Walter G. Swart, 808 Sellwood Bldg., Duluth, engrs.

Missouri

ST. LOUIS—D. A. Blanton Co., 2nd and Spruce Sts., has awarded the contract for the construction of a 2-story, 73x151-ft. oleomargarine factory at 319-23 South 1st St. and 101-11 Spruce St., to the Kellerman Constr. Co., International Life Bldg. Estimated cost, $50,000.

ST. LOUIS—The Emerson Electric Co., 2100 Washington St., has awarded the contract for the construction of an 8-story, 129x150-ft. factory at 2012-20 Washington St. and 2011-19 St. Charles St., to the Murch Bros. Constr. Co., Ry. Exch. Bldg. Estimated cost, $400,000.

ST. LOUIS—James D. Howe, 5811 De Giverville St., has purchased a site on the Natl. Bridge Rd., and plans to construct a 3-story, 117x250-ft. factory for the manufacture of patent medicines. Estimated cost, $20,000.

New Hampshire

NORTH STRATFORD—The Warner Sugar Refining Co., 79 Wall St., New York City, plans to build a sugar refinery. Estimated cost, $1,000,000.

New Jersey

TRENTON—The Mercer Motor Co., Whitehead Rd., will soon award the contract for the construction of a 1-story, 80x400-ft. paint shop addition to its plant. Estimated cost, $50,000.

VERONA (Montclair P. O.)—The Eagle Rock Mfg. Co. is having plans prepared for the construction of a 2-story, 40x350-ft. factory for the manufacture of moving picture films. Estimated cost, $250,000. Lockwood, Green & Co., 101 Park Ave., New York City, archts. and engrs.

New York

OGDENSBURG—Williams & Johnson, archts., are preparing plans for the construction of a factory for the manufacture of electrical fixtures, plumbers' supplies and brass articles, on the Wright property in the East End of city, for Cooper's Brass Wks., Inc. Estimated cost, $100,000. Address R. J. Donahue, Ogdensburg, or Abraham Cooper, 16 Nassau St., Brooklyn.

WATERTOWN—The Bagley & Sewall Co., mfr. of paper-making machinery, has purchased a site in the vicinity of its plant on East Moulton St., and plans to build a plant for the manufacture of pulp screens. The company recently acquired the equipment and good will of the Harmon Machine Co., manufacturer of the "Harmon Inclined Pulp Screens."

Ohio

CINCINNATI—The Rapid Electrotype Co., Canal, Race and Elm Sts., has awarded the contract for the construction of a 2-story, 100x215-ft. factory on McMicken, Race and Elm Sts., to L. Schrieber & Sons, Ivanhoe Ave.

CLEVELAND—The National Carbon Co. has awarded the contract for the construction of a 1-story, 120x180-ft. furnace building on West 117th St. and Madison Ave., to the Crowell, Lundorff, Little, Bicknell Co., 5716 Euclid Ave. Estimated cost, $200,000.

WARREN—The Goheen Mfg. Co. has awarded the contract for the construction of a 5-story, 50x125-ft. paint factory, to the Craig-Curtis Co., 1031 Guardian Bldg., Cleveland. Estimated cost, $200,000.

Oklahoma

WILBERTON—The city is having preliminary plans prepared for the construction of a 6 to 12 in. pipe sewer, sewage disposal plant, and 13,000 ft. of flow line and main extensions. An Imhoff tank will be installed in same. Estimated cost, $100,000. V. V. Long & Co., 1300 Colcord Bldg., Oklahoma City, engr.

Oregon

ASTORIA—W. H. Goodnough and associates plan to construct a 2- or 3-story, 50-ton daily capacity, pulp and paper plant and have asked the Port of Astoria Comn. to investigate a site for same. Estimated cost, $500,000.

Pennsylvania

FRANKFORT (Philadelphia P. O.)—The Belmont Packing & Rubber Co., 133 North 2nd St., Philadelphia, plans to build a 2 story, 120x120-ft. factory. Estimated cost, $60,000. Carl P. Berger, South Pennsylvania Square Bldg., archt.

Wisconsin

MILWAUKEE—The Central Bd. of Purchases, City Hall, will soon award the contract for furnishing 35,000 lb. of liquid chlorine.

Ontario

CHATHAM—The city plans to construct a new water system, to include rapid sand filters, 250,000-gal. steel tank, etc. A by-law appropriating $300,000 for the project has been passed. E. A. James Co., Ltd., 36 Toronto St., Toronto, engr.

OWEN SOUND—The Aluminum Steel Products, Ltd., plans to build an extension to its plant. Estimated cost, $250,000.

SCARBORO—The town plans to construct two pumphouses to be equipped with rapid sand filters, chlorinating apparatus, etc. A bylaw appropriating $300,000 for this project has been passed. E. James Co., Ltd., 36 Toronto St., Toronto, engr.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention in St. Louis, May 10 and 11.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23 to 26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will have a joint meeting with the American Chemical Society and the Society of Chemical Industry, Feb. 6, 1920. On Feb. 27 another meeting will be held, the subject for which is "Electric Furnace Reducing Agents." Another meeting will be held on March 26, the subject of which is Peace Uses for War Products.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16 to 19.

THE FARADAY SOCIETY (London) will hold a joint meeting, March 1, with the London Section of the Society of Chemical Industry to receive and discuss a report of Dr. T. Martin Lowry, and E. C. Hemmings on the "Setting of Salts and Other Crystalline Substances." Another meeting will be held March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W., 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE MATERIAL HANDLING MACHINERY MANUFACTURERS' ASSOCIATION has found it necessary to change the date of its convention at the Waldorf-Astoria Hotel, New York City, from Jan. 29 and 30, to Feb. 26 and 27.

Industrial Notes

THE ROYAL GRAND OIL CO., El Paso, Tex., plans the addition of another unit of 1000-bbl. capacity to its El Paso refinery. This will give a total capacity of 2000 bbl. of crude oil daily.

THE CLIMAX MOLYBDENUM CO., which is associated with the American Metal Co., 61 Broadway, New York City, now has in press a 72-page book on molybdenum commercial steels. The book is the first of its kind to be published, and contains tables, colored charts, microphotographs and other illustrations. It will be sent upon request without charge.

THE NORVELL CHEMICAL CORP., of Perth Amboy, N. J., was incorporated Jan. 1, 1920, in the State of Delaware with an authorized capital of $1,000,000 of preferred stock, and with 20,000 shares of common stock, no par value. The company has taken over from McKesson & Robbins, Inc., the property near Perth Amboy, N. J., consisting of 350 acres of land and a number of factory buildings erected on the property, purchased last year by McKesson & Robbins, Inc., also additional works which have since been constructed on the property, and will operate the plant, supplying the medical profession and the drug trade with pharmaceutical chemicals and the industries with chemicals useful in the manufacture of a variety of products. The company has gathered a staff of highly trained chemists for research work and expects to develop new and useful processes for the manufacture of chemical products. At a stockholders' meeting held at the temporary New York office at 11 Cliff St., the following directors and officers were elected: President, Donald McKesson; vice-president and treasurer, Saunders Norvell; second vice-president, Francis J. McDonough; secretary, William S. Gray, Jr.; assistant treasurer and assistant secretary, James J. Crawford. George Simon was appointed general manager.

Federation of Engineering Societies

FOR a decade or more those who have administered the affairs of our engineering societies, both national and local, have been aware of a growing sentiment in favor of some form of federation or aggregation that could represent the entire engineering profession of the country when united action was necessary. This tendency has found expression locally in the formation of clubs or joint societies, and nationally in the organization of Engineering Council, which represents its five constituent bodies in their varied relations with the Government and the public.

Subsequent to these developments the four founder societies of civil, electrical, mechanical, and mining and metallurgical engineers made a searching internal examination of their own aims and organizations, their relation to local sections and service to individual members. In addition to special reports submitted directly to some of the societies, a general report by a Joint Conference Committee was prepared for the consideration of all. Among other things it proposed a comprehensive federation of national, state and local engineering societies of the whole country. The proposed federation is on a more democratic basis than that underlying Engineering Council, membership in which is limited to national bodies.

It is significant of the drift in society affairs that at a recent meeting of the governing boards of its constituent bodies, called by Engineering Council, this report of the Joint Conference Committee was discussed and adopted in principle. By formal resolution the Joint Conference Committee was requested to "call without delay a conference of representatives of national, local, state and regional organizations to bring into existence the comprehensive organization proposed." This is without doubt the most important step yet taken toward the federation of all engineering societies and the unification of engineering interests. Since most of the dissatisfaction with previous engineering society activities has emanated from local sections of the national bodies or from independent local organizations, it follows that a successful federation must give close attention to the welfare of local bodies. By the same token, local societies must give a hearty response to the invitation of the Joint Conference Committee and realize that through the proposed federation they have for the first time an opportunity to voice their sentiments and exert an influence for the benefit of engineering as a whole. We will follow with the greatest interest the progress of the forthcoming conference, because it promises what has long been needed. Whether or not it will meet expectations depends wholly on the vision and constructive ability of its leaders.

Army Reorganization and the Chemical Warfare Service

THE other day a man came to us with a problem. He had his market and his sales organization planned, but he did not have his product in the form desired. What he wanted was, first, the thing itself with a new finish, and second, the technique of manufacture. So he proposed to "hire a chemist," rig up a laboratory, and set him to work. It was a problem in physical chemistry, although the promoter was not aware of the fact, and he thought any bright young fellow with a technical education should be able to crack the nut for him.

Now, any bright young fellow might succeed, but the chances are against it. As soon as complicated problems are attacked the factor of *esprit de corps* enters into research. A well-organized laboratory brings a number of minds to bear upon the solution of major problems. In it, invention becomes a habit, and contributions that lead to the complete answer are but incidents in the day's work. A research laboratory that gets results is like KIPLING'S Ship That Found Herself, and the co-operation of the staff is something more than a text for speeches. Co-operation becomes a veritable thing rather than a vague idea, and it generates energy.

The Chemical Warfare Service of the United States Army is still a thing, an organization, a body of men working together with the necessary *esprit de corps*. Its members co-operate. It is organized to get results. This is, however, almost a miracle, because it has been attacked from without and from within the Army. Two conflicting ideas are current about it, one of which was originally embodied in the House bill on the reorganization of the Army, and the other is that of the Senate. We understand from the latest reports which have come in that the sub-committee of the House has revised its proposal in this respect, but the danger still threatens. It was proposed that the Chemical Warfare Service be made a part of the Bureau of Ordnance. This reflects the opinion of many officers who did not get overseas during the war, and it may meet the approval of the Secretary of War. It conforms to the old traditions. Ordnance is an old department and it takes precedence. It makes sure of a West Point man in command; and to command is just what a West Point graduate is trained to do. An irreverent person undertook to imagine a battalion of chemical sergeants, corporals and privates at work in a laboratory as a certain exalted military authority in Washington would have it administered and according to such Laboratory Manual of Arms as his attitude toward the subject suggests.

The men stand in place, each one before his table with a test-tube. The commands follow: Grasp—Reagents!

Uncork—Bottles! Battalion—Pour! Agitate—Test-Tubes! Observe—Reaction! Titration Squad, Right—Face! Column of Twos, Forward—March! (They proceed to titration room and take places. Titrate—Solution! Titration—Halt!

That would provide a certain kind of *esprit de corps*, but not the kind that gets results. And it isn't done as far as we have observed in any of the laboratories that enjoy the habit of success. Men may be taught to obey commands, but chemical reactions are sometimes baffling and military "organization" cannot hope to train elements and compounds to perform at will.

The Senate sub-committee, on the other hand, recommends that the Chemical Warfare Service be made a separate department. This is as it should be. How can a body of chemists be made subject to the changing administration of officers in rotation, whether they be Ordnance officers or members of the Corps of Engineers? Of course it can be done, but it spoils the operation. It is born of the idea that a West Point man can do anything. We hate to deny cherished traditions, but we make bold to say that one West Point graduate differs from another in knowledge, ability, character and capacity. And we do not hesitate to add that the training in chemistry in the West Point Military Academy course is and must remain wholly inadequate to equip a good, modern research chemist. Chemistry is a profession. It is not a side line.

By making the Service part of the Ordnance Corps it will be elastic, they say, and it may be decreased to a minimum in time of peace and increased in time of war. In fact, as a kind of fifth wheel to the Ordnance Division it can be reduced to a nice round zero, which is just what is likely to happen. As part of the Ordnance Department it will also have to behave like a superfluous child and get out of the way. It is more likely to be regarded as a nuisance than as an arm of the service. Every chemist knows that a research department in chemistry must be a continuous and going concern, and that it cannot run by fits and starts and accomplish results. The whole proposition is as reasonable as if the General Electric Co. were to "reorganize" its research laboratory, discharge Dr. WHITNEY and the splendid corps of men who work with him, appoint a member of the finance committee as head of the laboratory organization, and then "recruit" young graduates to proceed with research. Obviously such disorganization would be disastrous.

We do not profess to know how to manage the War Department. On the other hand, we do claim to be somewhat familiar with chemical research and achievement. And experience teaches us that the highroad to failure is to take the spirit out of a department of research by putting it under the charge of first one and then another man who has no clearer grasp of chemistry and physics than the average graduate of a military academy. As a separate service it can remain under the men who have studied its requirements and know what is needed. As a separate service it will also invite other men of adequate military training to prepare themselves for a career in it. It will make the corps stand upon its own feet and be responsible for what it does. It will keep the Army up to date and make it ready to meet the enemy when he arrives in his might. In the name of common sense, is it not time to put aside the petty politics of rank and precedence, and to plan for results rather than for favor? Haven't we already suffered enough from this kind of quibbling?

Industrial Value of the Oxy-Acetylene Flame

MEN of the industry who are engaged in the actual operation of chemical plants have been quick to realize the value of the oxy-acetylene flame. When it is so necessary to keep the materials moving and the processes continuous, where there is a loss of precious time to tear out heavy castings for replacement, this tool in the hands of the trained welder has become invaluable.

And, incidentally, as a sidelight on the article appearing elsewhere in this issue, is to be noted the value of training the man to take pleasure in his work as an artisan. We have given too much thought to the creation of "foolproof" machinery and too little attention to the development of the imagination in the worker. Many thinkers are coming to realize that our future industrial growth must depend on the development of the human factor.

The Railway Administration And the Quest of Truth

THE assistant director of the United States Railway Administration decided that the meeting of the American Association for the Advancement of Science at St. Louis was not of a "religious, charitable, educational, fraternal or military character," and therefore the reduced rate of two cents a mile was not allowed. The plutocratic professors and teachers who attended had to pay the full rate of three cents a mile.

Perhaps the director had heard of the millions which the colleges were raising for endowment so that professors' salaries might be raised to the same level as those of window washers and day laborers. Or maybe the popular ouija board gave the answer, which suggests that the director moved in a mysterious way his wonders to perform. Anyhow, the problem was too knotty for officialdom to solve in a common sense manner.

In order to strike the heart of public servants rather than the heart of the people it might be advisable for the Association to change its name. Inasmuch as it has to do with science, it can hardly be classified as educational. There is too much, too great, too ponderous and too urgent authority against such a concept for the assistant director to rule otherwise than as he did. But if the Association were to re-name itself the Ancient and Honorable Fraternal Order of Cheiracanthi of the Scientific Sea, it might get by with it. That would make it fraternal—and worthy to the official eye.

What of The Breweries?

THE problem of converting a large brewing establishment to the manufacture of new products under the prohibition law offers a field of constantly increasing interest to the food chemist. Food chemist is said advisedly. Because of the large sales organizations in touch with wholesale grocers and food dispensers, and because of the factory personnel trained to work with cleanliness so necessary in brewing, the logical procedure calls for the manufacture of food products in these disused plants.

One fact seems evident. Large concerns because of their capacity cannot expect to convert their plants to the production of but one line, but must consider several. Candy, ice cream, maltose—that corn product

sweeter and more appetizing than glucose—malted milk, vegetable oils, and cereal beverages, are but specimens of related foods which may all be made in the same factory and marketed through the organized sales force of a modern brewery.

Exceptional opportunity for the food chemist thus exists today. When the research work now being carried on by these chemists becomes manifest in new industrial processes during the coming months one may again say, as many times heretofore, but alas! in a cup which somehow seems unfinished, "Here's to the chemist!"

Economics or Psychology

MARKET prices, including steel market prices, are made in various ways, and an interesting question now is whether prices in the nearby future are going to be made by economic or psychologic laws or influences. It may be granted that in the long run economic influences dictate prices; that is, they dictate the average of prices, but on the other hand it is obvious from any scrutiny of a typical market over a period of a few years that prices at individual moments cannot have been solely at the dictation of economic influences, for the economic influences could not change as facilely as prices have changed. Perhaps it is not far out to suggest as a rough generalization that the long swings are produced by economic influences and the fluctuations by psychologic influences.

The steel market at the present moment presents a very interesting case of economics and psychology. The United States Steel Corporation has been adhering rigidly to the "Industrial Board" price schedule, which means the war control prices minus the reductions that were made in December, 1918, and the further reductions that became effective March 21, 1919, as a result of an agreement between Secretary REDFIELD'S Industrial Board, which a few weeks later resigned, and representatives of the steel industry. The independents, on the other hand, have been advancing prices in rather irregular fashion and at the same time have been selling quite sparingly so that they have kept their order books relatively clear, obviously in the expectation that delaying sales will mean the realization of higher prices.

The Steel Corporation's position may be said to be held from economic considerations, the ground of the independents from psychological considerations. The Steel Corporation management evidently feels that over a period of years the general course of prices ought to be downward, and that any movement in the opposite direction, being contrary to economic laws, would eventually bring retribution.

The independents, on the other hand, evidently feel that buyers are willing, even anxious, to pay high prices for steel without having any definite limit beyond which they would be unwilling to go. Price advances make buyers more anxious to buy, and while sales are necessary in order that profits may be realized, to abstain from selling for a time is to bring greater profits, because later the material can be sold for more money.

The history of the steel market can be searched carefully without conclusive testimony being furnished as to whether economics or psychology has predominated in making the market. Usually there has been little theorizing by the leaders of the steel industry as to how the steel market is made, and what has been said has not always been illuminating. ANDREW CARNEGIE, for instance, who was quite a successful steel manufacturer as well as an excellent salesman, predicted late in 1898, on the eve of his departure for a trip in Egypt, that steel had a great tonnage future, for the reason that three pounds could be purchased for 2 cents, referring to $15 billets, saying also that a producer with bonded indebtedness could not expect to succeed, referring to his rival the Illinois Steel Company. Next year billets advanced above $40 and not long afterward Mr. CARNEGIE became the largest bondholder of a heavily bonded enterprise, the United States Steel Corporation. Then in 1908 Judge GARY, the astute head for nineteen years of the Steel Corporation, in connection with the "Gary dinner" or price maintenance movement, asserted, as to price reductions, that the volume of sales and purchases would not be increased or diminished, but whether he based this statement upon economic or psychological considerations is not known. Perhaps the idea was that from economic considerations the volume of purchases would be increased if the cost of the steel were less, but from psychological considerations buyers might be expected to be less disposed to buy through fear that one reduction merely indicated that another would follow, and thus the two influences, the economic and the psychological, might balance.

As to the actual market movements, which may be studied in the absence of any definite doctrine propounded by the authorities, one may possibly conclude that advancing movements in the market have been helped by psychological influences, while declines have been forced by the laws of economics. When prices begin advancing, buyers are moved to buy to avoid paying still higher prices, and as consumers buy, the sellers, becoming filled farther and farther ahead, are fortified to make additional price advances, all of which is psychological. Eventually the market is sold to a standstill, consumers find themselves with sufficient stocks and a free flow of material to them, adequate to their consumptive requirements, and the economic situation dictates that consumption can be stimulated only by waiting awhile and then beginning the process over again with attractively low prices.

Hence the interesting thing about the present situation is that, while in the past we have had psychology at one time and economics at another time in the steel market, now we have both at the same time.

The Woman And the Serpent

WE HAVE always welcomed the advent of women in science. They are supposed to be endowed by nature with a peculiar curiosity and that is one of the most needed attributes of those engaged in research. The curiosity of women is certain to differ from that of men, and by its very differences it should broaden the scope of the search for scientific truth. This is made manifest in a contribution to *Science* by Miss MABEL C. WILLIAMS of the State University of Iowa. With the aid of two assistants and suitable apparatus, which included a Deprez marker, a time indicator, a battery, some fine copper wire, a curved brass plate, etc., she determined the rapidity with which a rattlesnake wiggles its tail. The extremes ranged from 100 to 500 shakes per second.

Thus is science enriched with a bit of information quite as startling as the sound of the rattler itself.

Western Chemical and Metallurgical Field

Plant of the Olympic Portland Cement Co.

BY FAR the larger portion of the portland cement manufactured in this country is made by the well known "dry process," but what is termed the "wet process" is gaining in favor where the nature of the raw materials is such as to justify the use of this method. The wet process differs from the dry in that the raw materials are ground wet and the slurry thus produced is fed to specially constructed kilns; the treatment of the clinker is the same in both processes. The more obvious advantages of the wet process are two: first, the avoidance of dust both in that portion of the plant where the grinding and mixing of the raw materials are performed, also in the practical elimination of dust from the gaseous products of the kiln; and, second, the ease of obtaining a kiln feed of the required composition.

The first "wet process" mill to be built in this country is that of the Olympic Portland Cement Co., Ltd., at Bellingham, Wash. The plant was designed and constructed by the F. L. Smidth Co. for English capital, a fact that is obvious in the substantial construction of the buildings and equipment, particularly noticeable in the heavy concrete foundations for all machinery. The plant management claims that this expense is amply justified from the point of continuity of operation and few repairs. The present capacity of the plant is 2,000 bbl. per day; this can be doubled by the installation of additional equipment, a provision allowed for in the layout of the plant.

Raw Materials

The raw materials consist of a highly crystalline limestone and a glacial clay. The limerock is obtained from Balfour, Wash., the coarse-crushing plant being located at the quarry. The rock is crushed to pass a 3-in. ring and delivered to a 9,000-ton enclosed storage bin at the plant in standard bottom-dump, 50-ton steel cars. The clay is obtained from Brennan, Wash., being loaded into special 50-ton steel cars by a locomotive crane. At the plant the clay is excavated from these cars by a clamshell bucket-excavator operated from a traveling crane and delivered to a 7,000-ton storage basin. This same equipment is also used to transfer the clay from storage basin to the wash mill. The gypsum which is added in the final grinding operation is obtained from Montana.

The raw clay contains about 30 per cent moisture, and a further 30 per cent of water is added in the wash mill. This mill is a circular reinforced-concrete basin, 25 ft. in diameter by 6 ft. deep, in which the clay and water are added in batches and thoroughly mixed by revolving drags. The resulting slurry, when thoroughly incorporated, flows from the wash mill through a screened gate into either of two agitation basins, from which it is pumped by Smidth slurry pumps to receiving tanks located so as to feed by gravity two No. 85 Smidth Kominuters. The limerock is elevated to feed hoppers, also located above the Kominuters, by Link-Belt bucket elevators and a belt conveyor. The limerock is fed to the Kominuters at a constant rate, being controlled by an apron conveyor, the rate at which clay-slurry and water is fed to the Kominuters being controlled by gate valves; the desired proportion of clay, limerock and water is thus obtained. The excess of clay-slurry overflows from the receiving tanks and is returned to the agitation tanks. The feed to the Kominuters contains about 18 per cent dry weight clay, 82 per cent dry weight limerock and sufficient water to produce a 33 per cent slurry. The product of both Kominuters flows to a 22 x 7 ft. No. 20 Smidth tube mill containing 36,000 lb. beach pebbles. The product of the tube mill is elevated by concrete enclosed bucket elevators and fed to two 10 x 6 ft. No. 18 Smidth tube mills each containing 34,000 lb. "cylpebs." The product of these mills is elevated separately and after passing through Trix mills to screen out the oversize, which is returned to the Kominuters, flows by gravity to one of three 200-bbl. (dry weight) reinforced-concrete correction-basins provided with mechanical agitation, where the slurry is held until a laboratory analysis is obtained. The material is ground to 93 per cent through 200 mesh. The slurry flows from the correction basins to a 1,000-bbl. reinforced-concrete agitation basin and a check analysis obtained. It is then pumped by air lift pumps to either of the two 2,000-bbl. reinforced-concrete storage basins located in the kiln building.

The Kiln Building

The kiln building contains two 170-ft. Vulcan rotary kilns and the necessary auxiliary equipment. The kilns are specially designed for burning slurry, the first 30 ft. from the stack, or feed end, being fitted with "lifters" which elevate the slurry and drop it through the heated gases. The material after passing through the "lifting zone" contains about 10 per cent moisture. This operation effectively removes the cement dust from the gases passing through to the stacks, but does not retain all the ash from the coal dust which is used in firing the kilns. The first 130 ft. of the kiln from the stack end is 9 ft. in diameter, the remaining 40 ft., termed the combustion zone, being 10 ft. in diameter. The kilns are lined with 9-in. firebrick throughout and are connected through a dust chamber to reinforced concrete stacks, 175 ft. in height by 8 ft. in diameter. The slurry is fed to these kilns from supply tanks through gate valves, being pumped from the storage basin by Smidth slurry pumps; the excess overflows from the supply tank and is returned to the storage basins. The hot clinker from the kiln passes through a Smidth double-jacketed air-cooled clinker-cooler, the heated air being forced by a Buffalo Forge Co. slow-speed fan through the cooler and into the kiln, supplying the air necessary for the combustion of the coal dust. The cooled clinker is elevated by a Link-Belt bucket-elevator and delivered to a 180,000-bbl. enclosed clinker storage.

The coal is received from Nanaimo, B. C., on floats at the company's docks and unloaded by a 17-ton locomotive crane into 50-ton bottom dump cars and transferred to an enclosed storage bin. The coal is dried in a Cummer drier and pulverized to 97 per cent through 100 mesh by a Smidth Kominuter and No. 18 Smidth tube mill. The coal will contain about 20 per cent ash and runs about 11,000 B.t.u. per lb.

Finishing-Mill

The finishing-mill contains two No. 85 Smidth Kominuters and two No. 20 Smidth, 20 x 7 ft. tube mills, each containing a 15-ft. section of beach pebbles and a 5-ft. section of "cylpebs." The cement is ground to

pass 55 per cent through 100 mesh and 90 per cent through 20 mesh. About 3 per cent gypsum is added to the clinker entering the Kominuter, this being necessary to retard the setting time of the finished cement. The cement is transferred by belt conveyors to ten 1,000-bbl. reinforced concrete silos in the packing building. From these silos the cement is delivered through a hopper to an enclosed screw conveyor and bucket elevator to either of two four-bag Bates-valve packing machines; the bags are loaded direct into cars by a belt conveyor.

All operations involving the transfer of materials are performed mechanically, the quarry, clay-pit and plant being operated throughout by electricity, practically all equipment being fitted with individual motor drives. The present operating force is 103 men. The possibility of recovering potash was thoroughly investigated, but the amount contained in the clay proved to be too small to permit of economical recovery.

Company Reports

Burma Corporation, Ltd.—The annual report of the Burma Corporation for the year 1918, issued Oct. 31, 1919, contains information regarding the company's ore reserves, production and proposed metallurgical developments. Ore reserves at the end of 1918 were 4,404,000 tons assaying 24.1 oz. silver, 26.2 per cent lead and 18.4 per cent zinc; this includes 283,000 tons of copper ore assaying 21.6 oz. silver, 14.2 per cent lead, 8.7 per cent zinc and 10.2 per cent copper. The smelter production for 1918 was 18,641 tons of refined lead and 1,970,614 oz. refined silver. The development of the mines has been satisfactory, but the metallurgical problems have required a great deal of study and experimentation.

Lawrence Addicks is consulting engineer for the Burma Corporation and the following is abstracted from his report: The program for the coming year (1920) calls for the mining of 1,500 tons ore per day; beginning the operation of the mill on the "preliminary" flow sheet; erecting a standard type lead smelter near the mill, comprising crushing plant, roasters and blast furnaces fully equipped with bag-houses for 750 tons a day charge; erecting a modern Parkes process plant to refine 200 tons of lead bullion per day; erecting a 100-ton per day middling plant in England, provided tests show resulting zinc concentrates already produced are acceptable smelting product; proceeding with the erection of a 25,000-ton per annum zinc smelter at Jamshedpur, India, and developing copper metallurgy on an experimental basis. As the result of investigations and experiments carried out during the past year Mr. Addicks concludes "that it is extremely improbable that any of the many processes considered will ever be able to treat lead concentrates of the cleaner grade (that is, lead-zinc ratio of perhaps six to one) from the mill, and that a modern lead smelter (should) replace the plant now in use. The improved costs and higher recoveries resulting justify this replacement the moment we admit that no chemical process will render smelting obsolete. The question of relatively pure zinc concentrates has already been met in similar manner by the plant to be built at Jamshedpur." The conclusions are very interesting. In view of Mr. Addicks' familiarity with electrolytic methods, an electrolytic zinc plant and lead refinery would have been expected.

General Chemical Co. Buys Western Chemical Plant at Denver

It has been announced that the Western Chemical Manufacturing Co. of Denver, Col., has sold a controlling interest in its Denver works to the General Chemical Co.

The consideration has not been made public, but the physical valuation of the property is about $2,500,000. This plant has been in operation for many years, in the roasting of sulphide ores of the Colorado mining districts for the manufacture of sulphuric acid. The plant is especially adapted to making chemically pure nitric, sulphuric and hydrochloric acids and ammonia, and operates large acid chambers together with the contact acid plants. A zinc-lead smelter and electrolytic plant have also been recently constructed on the property for the recovery of the metals of the ores in the form of matte, paint basis, electrolytic zinc and cadmium.

With the largely increasing demand for acids in the Western district, there is little doubt that the present capacity of this plant will be increased by the new management.

Frank R. Ashley, president; L. B. Skinner, vice-president and general manager; A. K. McDaniel, assistant general manager, will withdraw from active part in the affairs of the plant, but will retain stock in the General Chemical Co. Paul C. Skinner, who has played an important part in the successful operation and growth of this property, is to continuue actively with the new management.

The General Chemical Co., under the arrangements made, will take a controlling interest in the local company's stock in exchange for its own.

St. Louis as a Steel Center

The United States steamboat H. S. Taber, with two of the new Federal steel barges built for upper river use, recently arrived in St. Louis with the initial shipment of Minnesota ore for St. Louis blast furnaces. Enthusiasts say this marks a new epoch in the steel industry in this district, where it is hoped that the combining of easy access of the ores from the Mesaba Range with Illinois coal will make it possible to produce steel fully as cheaply in St. Louis as in any other section of the United States.

In the Government fleet constructed for this purpose, there are nineteen barges and four towboats. The equipment has been leased by the Mississippi Valley Iron Co. of St. Louis, which will use it for the movement of Illinois coal into St. Paul and the Northwest. Returning, the boats will bring iron ore from the Minnesota mines.

These barges are 300 ft. long, 28 ft. wide and 10 ft. deep and will carry 3,000 tons on a 9-ft., 2,500 tons on an 8-ft. and 850 tons on a 4-ft. draft. During certain times of the year only may barges be loaded to full capacity. Seven of these barges have been completed and turned over to the Government. Five more are to be launched the first of the year. The towboats constructed for this use are 240 ft. long, all steel, of the stern wheel type and equipped with the latest machinery, having compound engines capable of developing 2,500 hp.

The unloading facilities in St. Louis are provided by the iron company, the ore being delivered directly at the plant. The trial trip has proved the equipment to be satisfactory in every respect.

Industrial Conference That Promises Results

At a meeting of the International Joint Conference Council in the printing industry, held in New York City recently, five cardinal points of labor policy were agreed upon. The Council is composed of representatives of the international unions of typographers, pressmen, bookbinders, and stereotypers and electrotypers, representing the employees; and of the Closed Shop Branch of the United Typothetæ of America, the Printers' League of America, and the International Association of Employing Stereotypers and Electrotypers, representing the employers. The adoption of these principles does not compel their acceptance either by the unions or the employers, but with these as a foundation the Council will outline a general policy which will be recommended to the members of the constituent organizations. They are incorporated in the scale just adopted for the magazine typographers of New York City.

The right of the workers or employers to organize, recognition of collective bargaining and the unrestricted right of the workers to select their representatives in wage conferences were not questioned. The cardinal points agreed to are as follows:

1. That the industry frankly recognizes the cost of living, as compared with 1914, as the basic factor in wage adjustments.
2. The industry to pay at least a reasonable living wage; scales below this to be adjusted in frank recognition of the basic principle involved.
3. That, when not in conflict with the existing laws of a constituent body, local contracts be for a period of not less than three years and include a clause providing for annual readjustments of wages based upon cost of living as determined by authorities jointly agreed upon, and upon the economic conditions of the industry at the time of readjustment.
4. That a uniform standard system of cost-keeping is considered fundamental to insure stability, permanence and prosperity to the industry, and to provide a basis for securing a greater degree of uniformity in conditions throughout the country; a clause to be included in local agreements providing that such a standard system as is recognized by the organizations represented in the Joint Conference Council be required.
5. That controversies over wages, hours and working conditions between employers and employees can and should be settled without resorting to lockouts or strikes, through voluntary agreements to refer disputes, where unable to settle through conciliation, to joint boards of arbitration composed of equal representation of employers and employees, provision being made for an impartial arbitrator if necessary.

It is evident that the employers as represented in the Council are willing to meet the employees half way. The international unions show a like spirit, and if the recommendations of the Council are adopted, and there is every reason to think they will be, and are followed in good faith by the members of the local unions, a repetition anywhere of the recent chaos in the printing industry in New York City will be impossible.

Also, while these principles doubtless would not be applicable to all industries, they might furnish suggestions for arriving at a better understanding between employer and employee and by providing for uninterrupted production during the adjustment of wage disputes bring nearer the time when economic conditions in the United States will again be normal.

Proposed Duty on Oxalic and Formic Acids

A duty of 5c. per lb. on oxalic acid and its salts is prescribed in a bill which has been introduced by Representative Wilson of Illinois. The bill also provides a duty of 3½c. per lb. on formic acid and its salts, including formate of soda.

Carnegie Corporation Aids National Academy of Sciences and National Research Council

The Carnegie Corporation of New York has announced its purpose to give $5,000,000 for the use of the National Academy of Sciences and the National Research Council. It is understood that a portion of the money will be used to erect in Washington a home of suitable architectural dignity for the two beneficiary organizations. The remainder will be placed in the hands of the Academy, which enjoys a Federal charter, to be used as a permanent endowment for the National Research Council. This impressive gift is a fitting supplement to Mr. Carnegie's great contributions to science and industry.

The Council was organized in 1916 as a measure of national preparedness, and its efforts during the war were mostly confined to assisting the Government in the solution of pressing war-time problems involving scientific investigation. Reorganized since the war on a peace-time footing, it is now attempting to stimulate and promote scientific research in agriculture, medicine and industry and in every field of pure science. The war afforded a convincing demonstration of the dependence of modern nations upon scientific achievement, and nothing is more certain than that the United States will ultimately fall behind in its competition with the other great peoples of the world unless there be persistent and energetic effort expended to foster scientific discovery.

Better Service Demanded From Patent Office

A bill introduced by Representative Tilson of Connecticut calls upon the Secretary of the Interior to direct the Commissioner of Patents to transmit to the House the facts in his possession concerning delays in the consideration of and action upon applications for patents. The bill points out that the Patent Office is supported by fees from inventors, manufacturers and others transacting business with that office, that each year the Patent Office turns a surplus into the Treasury. Since the inventors and others pay the running expenses of the Patent Office, they are entitled to better service, Mr. Tilson says.

Ramsay Memorial Fund

The United States Committee on the Ramsay Memorial Fund has transmitted £3,500 which it has collected; £263 has been sent direct by contributors; approximately £100 yet remains in the hands of the treasurer, W. J. Matheson. Prof. Baskerville, the chairman, hopes that the total American contribution, which is £3,863, may be raised to £4,000, and then close the American subscriptions. The total fund now amounts to £51,274. This is a very gratifying tribute to the memory of Sir William Ramsay, who did so much for pure science as well as the cause of the Allies during the recent war.

Omaha Chemical Club Formed

Commercial chemists of Omaha, Neb., recently organized the Omaha Chemical Club at a banquet held on Jan. 13 at the Loyal Hotel. Dr. H. A. Senter and Dr. A. W. Peters were the principal speakers. Both emphasized the necessity of organization among Omaha chemists to advance the needs of the profession. Attention was called to the lack of sufficient number and variety of chemical books in the library to serve the rapidly growing industrial needs of the city.

Carnegie Research Fund of the Iron and Steel Institute

In connection with the announcement of the annual meeting of the Iron and Steel Institute, to be held May 6 and 7, members are reminded that in March the Council is prepared to consider applications for grants from the Carnegie Fund, in aid of research work, of such value as may appear expedient, but usually of the value of £100 in any one year. The awards are made irrespective of sex or nationality. Special forms, on which candidates should apply before the end of February, can be obtained from the secretary of the Institute. The research work must be on some subject of practical importance relating to the metallurgy of iron and steel, and allied subjects. The results of research work must be communicated to the Institute in the form of a report.

Theta Tau Fraternity for Engineering Students

The Fourth Biennial National Convention of Theta Tau Fraternity was held at its Delta Chapter House, Case School of Applied Science, Cleveland, Ohio, during the week of Dec. 29, 1919.

Theta Tau Fraternity was founded at the University of Minnesota, Oct. 15, 1904, as an honorary fraternity of mining engineers. After the first three chapters were established, members were chosen also from mechanical, electrical, civil and metallurgical engineering students. Due to the rapid growth of the various branches of engineering, the convention favored the selection of members from sophomore, junior and senior classes in all branches of engineering.

Although heretofore the fraternity has been exceedingly reserved, an extension policy has been adopted and chapters are to be established in many American institutions having engineering departments of high standing.

The next national convention will be held at the University of Kansas, Great Bend, Kan., in 1921.

Chemical Warfare Service

No predictions can be made with any degree of certainty as to the outcome of pending legislation which may change the status of the Chemical Warfare Service, the construction division of the Army and the other services which were given a separate identity during the war. Despite the fact that the House Military Affairs Committee has been working on the Army reorganization bill for nearly a year, the committee has not yet agreed upon the bill that it will bring out. A sub-committee has recommended that the Chemical Warfare Service become a part of the Bureau of Ordnance, but it is not at all certain that the whole committee will accept this recommendation.

On the other hand, unexpected progress is being made with the Army reorganization bill in the Senate Committee on Military Affairs and it is possible that the bill may be reported in a short time. The section of the bill referring to the Chemical Warfare Service, which is established as a separate service, as reported by the sub-committee to the full committee, reads as follows:

"The permanent personnel of the Chemical Warfare Service shall hereafter consist of one chief of Chemical Warfare, with the rank of Brigadier General, and 125 officers in grades from Second Lieutenant to Colonel, inclusive, and 1,200 enlisted men in their appropriate grades, all of whom shall be detailed or assigned from the permanent personnel under the provisions of this act. The reserve personnel of the Chemical Warfare Service shall consist of all reserve officers and reservists assigned thereto as provided for in this act."

Mohawk Valley Engineers Organize

About 125 engineers, architects and chemists met at dinner at the Hotel Utica, Utica, N. Y., on Wednesday evening, Jan. 7, and organized the Mohawk Valley Engineers' Club. The membership of the organization includes civil, chemical, electrical, mechanical, mining, textile, heating and ventilating, automotive and all technical engineers and architects. The territory embraced in the jurisdiction of the club lies within a radius of approximately forty miles from Utica and it is expected that the membership will ultimately reach the 200 mark. Regular meetings will be held on the first Tuesday of each month. The officers for the first year are: President, Byron E. White, engineer of the Utica Gas & Electric Co.; first vice-president, Hubert E. Collins, consulting engineer; second vice-president, Roy F. Hall, division engineer, State Highway Department; third vice-president, Horace B. Sweet, consulting engineer; secretary, Frederick E. Beck, engineer of the Consolidated Water Co.; treasurer, Clifford Lewis, Jr., civil engineer.

National Research Council Advises Baking Industry

The American Association of the Baking Industry has begun work in Minneapolis, Minn., under the direction of Dr. H. E. Barnard, assisted by an advisory committee of the National Research Council, and in cooperation with the Dunwoody Institute. Bread production is to become a science. It has been found that by furnishing the yeast with certain stimulants and special chemical foods a saving of some of both the flour and the sugar formerly consumed by yeast during its growth is made. The scientific aid of the specialist on food and nutrition, agriculture, chemistry and physics of the advisory committee of the National Research Council will give the bakers the advantage of science for the improvement of bread-baking methods.

Research Graduate Assistantships in Engineering at University of Illinois

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen research graduate assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $500 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

An appointment to the position of research graduate assistant is made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Not more than half of the time of a research graduate assistant is re-

quired for the work assigned to him, the remaining time being available for graduate study.

The Engineering Experiment Station, an organization within the College of Engineering, was established in 1903 for the purpose of conducting investigations in the various branches of engineering, and for the study of problems of importance to engineers and to the manufacturing and industrial interests of the State of Illinois. Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil, electrical, mechanical, mining, and municipal and sanitary engineering, physics, railway engineering, and theoretical and applied mechanics.

Additional information may be obtained by addressing the Director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Disposal of Government Surplus Chemicals

Up to the end of 1919 the Government has disposed of surplus chemicals, acids and explosives to the extent of $31,954,010.57. The original cost of these supplies to the Government was $34,226,227.35.

British Chemical Industry

From our London Correspondent

London, January 7, 1920.

THE policy of amalgamation and understandings among chemical works continues and seems to be the natural consequence both of the experience gained during the war and of the trend of international competition to be expected in the future. As always, the end of the year was the signal for new issues and for increases in the capital of existing companies, rendered particularly desirable at the present time by the increasing amount of capital that has to remain tied up in stocks and material on hand of nominal value. There is continued activity and a general upward tendency in prices in all sections of the chemical trade, and considerable difficulty is experienced in obtaining prompt supplies of many products, buyers displaying anxiety to provide for their requirements for several months ahead. Competition from Germany does not seem to be feared for at least two years to come and the general opinion is that the coming year will be a busy and prosperous one, granted a reasonable absence of labor, fuel and transport difficulties.

The recent "pyrogallic acid" case has freed imports for the time being, but the position in regard to imports which were previously restricted will be somewhat risky, as the decision will either be reversed or legislation introduced to reimpose the restrictions.

Fuel Outlook Is Disturbing

The fuel outlook is still a disturbing factor, and as domestic supplies only were affected by the recent reduction in price, it is probable that a continuance at the very least of present prices must be faced by the chemical industry. As a result there is a general feeling that oil fuel must be resorted to in part, and the additional demand has already caused an increase in the price of fuel oil which can only be counteracted gradually as additional shipping becomes available for its transport. Considerable attention is also being devoted to the use of oil for auxiliary firing, especially in connection with low-grade coal, and to the possibilities of powdered coal and colloidal fuels. The possibilities of home-produced oil fuel are still treated with some scepticism, and development work is proceeding slowly. The experts' reports on the development of the Norfolk shale deposits owned by English Oilfields, Ltd., are considered ultra-optimistic and doubt is expressed as to the possibility of eliminating the large amount of sulphur usually found in such oils. The question of sulphur content is hardly mentioned in the report, which is calculated to give the impression that sulphur only occurs in isolated cases, an impression unlikely to be substantiated.

Nitrogen Products Committee Report

The final report of the Nitrogen Products Committee previously referred to[1] is to be published about Jan. 15, and owing to the inordinate delay, some of the figures and conclusions will be out of date. In general this country is less prompt and confident in disseminating knowledge acquired by government departments than the United States. The impressions and conclusions arrived at by a representative British mission sent to German chemical works by the Board of Trade and the Association of British Chemical Manufacturers were published for private circulation among members of the latter. Various items filtered through to the public in the form of addresses to local gatherings by members of the mission, but actually there is little in the report that could not have been published broadcast with advantage, particularly if done systematically as in the American technical press.

Chemists' Salaries and the Endowment of Science

The questions of chemists' salaries and the endowment of science at universities are again receiving attention, but in the latter case the sums asked for and forthcoming are minute in comparison with the munificent donations to American institutions. The future of the chemical industry is so closely bound up with these questions that those countries which take the lead quickly will reap the fullest advantage in the future. As regards the future of the British industry, a thoughtful contribution by E. F. Armstrong[2] sums up the position admirably.

Personal Notes

Sir Richard Redmayne has resigned his post of Chief Inspector of Mines in order to take up the work of chairman of the new Imperial Mineral Sources Bureau. The latter is the nucleus of an organization similar to the United States Bureau of Mines, and of course an institution of this kind should have been inaugurated many years ago in this country. David Gilmour, who as Director of the Factories Branch of the Ministry of Munitions controlled the erection and operation of some of the largest works in this country, has left for Canada to take up the appointment of president of the Standard Chemical Co., Ltd. Prof. Robinson, of Liverpool University, will be the new Director of Research of the British Dyestuffs Corp. Dr. J. E. Stead is the new president of the Iron & Steel Institute and Dr. C. H. Desch has been appointed to the chair of metallurgy at Sheffield University recently vacated by Dr. J. O. Arnold. Lever Bros., Ltd., is to build a large candle-making factory near Bath at a cost of about $5,000,000. It will be remembered that this firm recently acquired the business of Price's Patent Candle Co.

Electrolytic Production of Hydrogen

Theoretical Principles Involved in Calculation of Cell Efficiency—Commercial Cells—Metal Diaphragm, Filter Press or Bi-Polar, Suspended Diaphragm Tank and Non-Porous Non-Conducting Diaphragm Types — Hydrogen as Byproduct From Chlorine Cells

By HARRY L. BARNITZ, Ph.G.

THE decomposition of water into its constituent elements, hydrogen and oxygen, had been a matter of experiment in the chemical laboratories for more than a century. It finally remained for the remarkable developments of electrochemistry in the past generation, stimulated by the commercial demand for these gases, to produce a commercially practical water electrolyzer (also termed electrolytic cell).

In an embryonic form, decomposition of water may be effected by passing an electric current between two metallic poles, or electrodes, immersed in water. As water has great power of resistance to electric current, it is necessary to lower the resistance to allow a large current of electricity to pass. This is accomplished by adding to the water either acid or alkali, forming an electrolyte. The electrolyte proportionally raises the gas production.

There are two classes of substances which act as conductors for the electric current. The first class includes metallic conductors, such as copper, aluminum, brass, iron, mercury and some solid non-metallic substances, of which carbon is the most important. The passage of a current through these conductors is not accompanied by any change in the conductor, other than the development of a certain amount of heat. Members of the second class of conductors known as electrolytes are water solutions of acids, bases and salts. Some melted compounds also act as electrolytes—these will not be considered here, as they are of no importance in the production of hydrogen and oxygen.

The passage of current through an electrolyte is accompanied by the liberation of two different substances. One of these appears at the terminal where the current enters the solution, known as the anode, or + electrode, and the other at the terminal at which the current leaves, called the cathode, or — electrode. For an illustration, if two electrodes made of platinum plates are placed in a strong aqueous solution of hydrochloric acid, the one electrode being connected to the positive pole of the battery and the other to the negative pole, decomposition of the liquid will take place—hydrogen will be given off at the negative electrode or cathode and chlorine at the positive anode. If the solution of hydrochloric acid is replaced by sodium chloride, chlorine is liberated at the anode and sodium hydroxide is found in the solution surrounding the cathode.

Now let the solution of hydrochloric acid and sodium chloride be replaced by a solution of sodium hydroxide. The solution of sodium hydroxide is split up by the current into oxygen, which is liberated at the anode, and sodium ions, which lose their charge at the cathode and become sodium atoms with the escape of hydrogen. Again, the solutions of hydrochloric acid and sodium chloride and sodium hydroxide are replaced by an aqueous solution of sulphuric acid. In this instance, hydrogen will be liberated at the cathode and the SO_4 group at the anode, which immediately reacts with the water and forms a new molecule of sulphuric acid.

Copyrighted, 1920, by Harry L. Barnitz.

Electrolytic Dissociation Theory

Before attempting to explain this result it will be necessary to state the theory of electrolytic dissociation.

According to this theory, when an electrolyte is dissolved in water, a portion at least of its molecules break up into two parts, one charged with positive electricity and the other with an equal amount of negative electricity. These charged portions of the molecule are called respectively positive and negative ions. Thus, when sodium chloride is dissolved in water, equal amounts of positive sodium ions and of negative chlorine ions are produced. This may be indicated by the equation:

$NaCl$	$\leftrightharpoons$	Na^+	+	Cl^-
sodium chloride molecule		sodium ion		chloride ion

Hydrochloric acid dissociates in solution according to the equation:

HCl	$\leftrightharpoons$	H^+	+	Cl^-
hydrochloric acid molecule		hydrogen ion		chlorine ion

Sodium hydroxide dissociates in solution as follows:

$NaOH$	$\leftrightharpoons$	Na^+	+	OH^-
sodium hydroxide molecule		sodium ion		hydroxyl ion

It will be noted in these typical examples of the dissociation of a salt, an acid, and a base that the hydrogen ion and the metallic ion are positive, and that the non-metallic ions are negative.

In a solution of copper sulphate there are copper ions and sulphate ions:

$CuSO_4$	$\rightleftharpoons$	Cu^{++}	+	SO_4^{--}
copper sulphate molecule		copper ion		sulphate ion

A double charge is indicated here on each ion, as the number of charges which an ion carries is the same as the number expressing its valence. Molecules of the dissolved substance in an electrolyte, then, dissociate, on dissolving, into positive metallic ions and negative non-metallic ions. Hydrogen, in acids and acid salts, acts as a metallic ion; in bases it is a part of the complex non-metallic ion OH^-. The only important complex positive ion is NH_4^+, produced by the dissociation of ammonium hydroxide and the ammonium salts.

The proportion of the molecules dissociated at a particular time in a given electrolyte depends on the nature of the dissolved substance, the degree of dilution of the solution, and the temperature. Water is the only important solvent in which any considerable amount

of dissociation takes place. Many soluble substances, particularly organic compounds such as sugar, alcohol, and glycerine, do not dissociate on dissolving. Such solutions are known as non-electrolytes and are non-conductors of electricity. Pure water is a very poor conductor, and therefore its molecules are only slightly dissociated.

On the basis of the theory just stated the electrolysis of sodium chloride is easily explained. When the electrodes are dipped into the solution and the circuit closed, the Na^+ ions, which have been moving about at random in the solution, are immediately repelled by the positive electrode and attracted by the negative electrode, since like electric charges always repel and unlike charges attract. The Cl^- ions begin to move toward the positive electrode for the same reason. As soon as an ion reaches the electrode, the opposite charges on ion and electrode neutralize each other. The chlorine ion, losing its charge, becomes a chlorine atom; these unite in pairs to form molecules, and escape from the solution, when a sufficiently large number of such molecules have collected at the anode. The sodium ions in a similar way lose their charge at the cathode and become sodium atoms. These do not, however, unite to form pieces of metallic sodium, since they react with the water to form sodium hydroxide:

$$\underset{\text{sodium}}{2Na} + \underset{\text{water}}{2H_2O} \longrightarrow \underset{\text{sodium hydroxide}}{2NaOH} + \underset{\text{hydrogen}}{H_2}$$

Thus bubbles of hydrogen will escape at the cathode. The sodium ion did not react with the water, because the presence of the electric charge gives the ion chemical properties differing from those of the atom.

It may be now explained that when sulphuric acid is added to water to make it a conductor (considering the action first as an electrolysis of sulphuric acid) the acid dissociates on dissolving into hydrogen ions and sulphate ions:

$$\underset{\text{sulphuric acid molecule}}{H_2SO_4} \leftrightarrows \underset{\text{hydrogen ion}}{H^+} + \underset{\text{hydrogen ion}}{H^+} + \underset{\text{sulphate ion}}{SO_4^{--}}$$

As the current passes, the ions lose their charges at the electrodes. At the cathode hydrogen ions change to hydrogen atoms, which unite to form molecules of hydrogen. At the anode, SO_4^{--} changes to SO_4, which immediately reacts with the water as follows:

$$\underset{\text{sulphate radical}}{SO_4} + \underset{\text{water}}{H_2O} \longrightarrow \underset{\text{sulphuric acid}}{H_2SO_4} + \underset{\text{oxygen}}{O}$$

In the reaction a new molecule of sulphuric acid has been produced in place of the one originally dissociated and an atom of oxygen has been liberated. The oxygen atoms liberated at the anode unite to form oxygen molecules, which escape as a gas. The entire reaction therefore may be considered as equivalent to that shown by the equation:

$$\underset{\text{water}}{2H_2O} \longrightarrow \underset{\text{hydrogen}}{2H_2} + \underset{\text{oxygen}}{O_2}$$

In the commercial production of hydrogen and oxygen by electrolysis where a solution of sodium hydroxide or potassium hydroxide is used as the electrolyte, potassium hydroxide has a slightly higher efficiency than sodium hydroxide and was almost exclusively used prior to the war. Due to the high cost and great scarcity caused by the war, potassium hydroxide has been replaced by sodium hydroxide, although it is probable that potassium hydroxide will again be used when market conditions are favorable. The first action in the electrolysis is the dissociation of potassium hydroxide when it dissolves:

$$\underset{\text{potassium hydroxide molecule}}{KOH} \leftrightarrows \underset{\text{potassium ion}}{K^+} + \underset{\text{hydroxyl ion}}{OH^-}$$

When the potassium ion reaches the negative electrode, it loses its charge, becomes a potassium atom, and reacts with the water of the solution, forming potassium hydroxide again and liberating hydrogen:

$$\underset{\text{potassium}}{2K} + \underset{\text{water}}{2H_2O} \longrightarrow \underset{\text{potassium hydroxide}}{2KOH} + \underset{\text{hydrogen}}{H_2}$$

The hydroxyl ions, when they lose their charges, react with each other, forming water and liberating oxygen:

$$\underset{\text{hydroxyl}}{OH} + \underset{\text{hydroxyl}}{OH} \longrightarrow \underset{\text{water}}{H_2O} + \underset{\text{oxygen}}{O}$$

It will be seen that the net result of these reactions is the removal of one molecule of water from the solution and the liberation of two atoms of hydrogen and one atom of oxygen. So it is only the water in the cell which needs to be renewed and not the potassium hydroxide. The results of the reaction are identical if sodium hydroxide is used as the electrolyte.

Faraday's Laws

The dissociation theory having been stated, the theory of relationship between current and volume of hydrogen produced will now be considered.

The theory of relationship between current and volume of hydrogen produced is founded upon laws relating to the decomposition of liquids by the electric current, known as Faraday's laws. They constitute the basis of all electrochemical calculations, determining just how much chemical action is produced by a given flow of current for a given time. These laws are as follows:

1. The amount of chemical effect produced during electrolysis is directly proportional to the product of the current and the time; that is, to the quantity of electricity which flows through the electrolyte.
2. When a current passes through an electrolyte, bringing about chemical changes at the electrodes, the quantity of each substance formed is directly proportional to the equivalent weight of the substance and to the quantity of electricity which has flowed through the electrolyte.

It is obvious that if 1 amp. flowing for 1 min. will deposit a certain amount of silver, 2 amp. flowing for 1 min. will deposit twice that amount. Also that the amount which a given current will deposit in 10 min. is ten times as great as will be deposited by the same current in 1 min.

Electrochemical Equivalent

By knowing the equivalent weight, or, as it is more commonly termed, the chemical equivalent, of the material, the quantity of that material which will be liberated by a known amount of electric current can be readily calculated. Every substance, whether it be a chemical element or a chemical compound, has its electrochemical equivalent, just as it has a certain atomic weight; and in fact the electrochemical equiv-

alent is closely associated with the atomic weight. As many elements have more than one valency, therefore they have more than one chemical equivalent weight, as can be seen from the Table I.

TABLE I. CHEMICAL EQUIVALENT WEIGHTS

Element	Atomic Weight	Valency	Chem. Equiv. Wt. at. wt. / v
Hydrogen	1	1	1
Oxygen	16	2	8
Gold	197	3 or 1	65.6 or 197
Tin	118	4 or 2	29.5 or 59
Tungsten	184	6 or 4	30.6 or 46.0

It is found by experiment that a current of 1 amp. flowing for 1 sec. (one coulomb) deposits 0.001118 g. of silver from an aqueous solution of a silver salt. The atomic weight of silver is 107.94, its valency is unity, therefore its chemical equivalent weight is 107.94. However, the atomic weight of hydrogen is 1.0 and its valency is unity, therefore its chemical equivalent weight is 1.0; therefore it is obvious from Faraday's second law that $\frac{0.001118}{107.94} = 0.000010357$ g. of hydrogen will be liberated by 1 amp. flowing for 1 sec., or the mass of hydrogen liberated by any current in any time may be expressed as $1.0357 \times 10^{-5}At$, where A is the current in amperes and t the time it flows in seconds; which is equivalent to stating that, at 0 deg. C. and 760 mm. barometric pressure (29.92 in.) 1 amp.-hr. will liberate 0.0147 cu.ft. of hydrogen.

Factors Affecting Voltage Drop

It now remains to determine the relationship between power and the volume of hydrogen which should be theoretically liberated. It is evident that to get the current to flow through the electrolyte requires an electrical pressure, as all substances offer resistance to the passage of electricity through them. Therefore a voltage drop between the anode and cathode will be found in cells.

Two factors of resistance cause this voltage drop, one of which is analogous to the resistance of any conductor and is dependent on the length and cross-sectional area of the path of flow of the current—the distance between the electrodes. This resistance is called the back emf. of the cell, or polarization. The resistance in the first instance can be practically eliminated by placing the electrodes close together. The second factor is due to a constant of the electrolyte in the cell and is not caused by a function of cell design. Therefore it is obvious that the current must have a certain theoretical potential to overcome the polarization resistance of the electrolyte to obtain electrolysis in a cell.

Decomposition voltages are given in Table II for various aqueous solutions of bases, acids, and salts containing their chemical equivalent weight in grams per liter. These values are given for minimum voltage to produce continuous electrolysis in a cell whose resistance other than that due to polarization is negligible. These solutions vary in concentration, and it has been found that solutions whose minimum voltage is about 1.7 require no appreciable variation of pressure to produce continuous electrolysis.

Having previously ascertained, from Faraday's laws, that a current of 1 amp. for 1 hr. should produce 0.0147 cu.ft. of hydrogen (at 0 deg. C. and 760 mm. pressure), it is evident when a solution of sodium hydroxide is used, the current must be supplied at 1.69 volts, therefore 1×1.69 watt-hr. produces 0.0147 cu.ft. of hydrogen, or 1,000 watt-hr. produce $\frac{0.0147 \times 1000}{1.69} = 8.7$ cubic feet.

With the liberation of hydrogen at the cathode, oxygen is simultaneously evolved at the anode. Therefore, in accordance with Faraday's laws the volume of oxygen is one-half of that of the hydrogen and theoretically, in the electrolysis of a solution of sodium hydroxide, 1 kw.-hr. should produce 8.7 cu.ft. of hydrogen and 4.4 cu.ft. of oxygen at 0 deg. C. and 760 mm. (29.92 in.).

TABLE II. DECOMPOSITION VOLTAGES (Le Blanc)

Solution of	Minimum Voltage Volts	Solution of	Minimum Voltage Volts
Silver nitrate	0.70	Nitric acid	1.69
Hydrochloric acid	1.31	Zinc chloride	1.78
Potassium hydroxide	1.67	Zinc sulphate	2.35
Sodium hydroxide	1.69		

One of several of the more important commercial applications of the theory of electrolysis will now be described in the production of hydrogen and oxygen.

Types of Commercial Cells

Various types of electrolytic cells for the commercial production of hydrogen and oxygen have been developed. Only those types which are representative will be considered here. They all employ either sulphuric acid or a solution of sodium or potassium hydroxide as electrolyte. When the acid is used, lead is the material used in the cell construction, while with the alkaline electrolyte, iron is employed. This choice of materials is made because of the insolubility of lead and of iron in the respective solutions. It is apparent that insoluble electrodes must be employed to allow the escape of hydrogen and oxygen.

An important point to be attained in water decomposition is that the anode and cathode products be kept as completely separated as possible. The bubbles of the hydrogen coming off at the cathode surface must not mingle with the oxygen bubbles from the neighboring surface, otherwise impurity of products results.

The electrodes must be placed as near together as practicable. If the distance between the anode and cathode is great, the resistance of the cell is high and the production is much below the theoretical.

To obtain reasonably high purity in the gaseous products, some types of cells have a porous diaphragm placed between the electrodes; others have a metallic diaphragm. Cells employing a porous diaphragm create a certain amount of resistance, but they have the advantage of acting as a factor of safety and add to compactness.

A 20 to 30 per cent sulphuric acid solution has a higher conductivity than a 10 to 20 per cent alkali solution. On the other hand, it takes a somewhat higher electromotive force to liberate hydrogen and oxygen from the former solution, so that cells using sodium or potassium hydroxide have a slightly lower energy consumption than those using the acid.

Since the acid or alkali is unaffected by the electrolysis, it is only necessary to add distilled water from time to time to replace that electrolyzed.

The representative types of cells for the commercial production of hydrogen may be classed as:

1. Metal diaphragm type.
2. Filter press or bi-polar type.
3. Suspended diaphragm tank type.
4. Non-porous non-conducting diaphragm type.

Metal Diaphragm Type

The cell developed by Garuti and Pompili[1] is an excellent example of this type. In this cell a partition of iron separates the anode from the cathode, and this

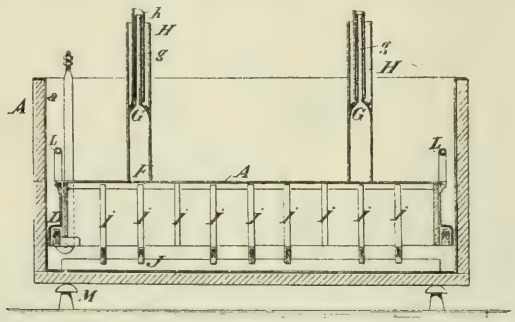

FIG. 1. GARUTI GENERATOR—VERTICAL LONGITUDINAL SECTION

partition is prevented from becoming an intermediate electrode by keeping the voltage applied to the cell too low for this to take place. The current flows from the anode to the cathode around the bottom of the iron partition.

Fig. 1 is a diagrammatic longitudinal vertical section through the center, Fig. 2 is a horizontal section of one end, Fig. 3 is a vertical cross-section of the cell and Fig. 4 a plan view of conductors and electrodes.

Tank *A* of wood lined with iron *a* contains the electrolyzer, which consists of an inverted tank *A* which is divided into cells *E* by longitudinal diaphragms. This case is made of iron and is open only at the bottom. The anodes *b* and cathodes *c* are placed one

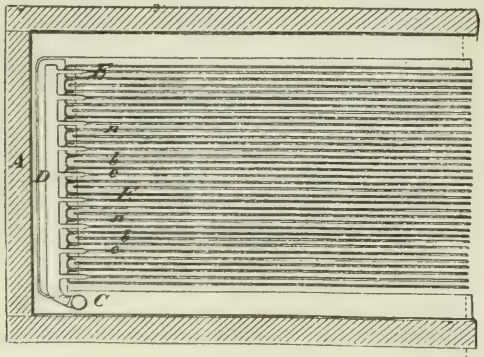

FIG. 2. GARUTI GENERATOR—HORIZONTAL SECTION

in each cell, taking care that each anode is between two cathodes. The gas passes through an opening at the top of each chamber into the gasometer containing the same gas. The electrodes are insulated from the diaphragms by combs *I* made of wood, the teeth of which enter the cells and fill the spaces between the electrodes and diaphragms. *L* is a handle for lifting out the electrolyzer.

The diaphragms may be perforated near the bottom with a large number of small holes, which reduce the electrical resistance, as there is very little danger of the gases becoming mixed at this point.

Using a 25 per cent solution of sodium hydroxide and a current density of 25 to 27 amp. per sq.ft., the gases being measured at 20 deg. C. and 760 mm. pressure, the electrolyzer produces 6.1 cu.ft. of hydrogen per kw.-hr. The purity of the hydrogen is 99 per cent and of the oxygen 97 per cent. This type of cell is quite compact but, owing to the small distance between the electrodes, care must be taken to prevent an internal short circuit in the individual cells.

Filter Press or Bi-Polar Type

In the filter press or bi-polar type cell the polarization or back emf. resistance of the cell from the original anode to the original cathode is doubled by the fact that the interposition of a conductor, to which no electrical connections have been made, turns the original cell into two cells, when the electrodes are placed together and insulated from one another.

The filter press or bi-polar type shown in Fig. 5 consists of a series of metallic plates (electrodes) clamped up together in a heavy frame, electrically insulated from one another, and separated by diaphragms of porous fabric.[2] Each pair of these electrodes forms a closed cell, divided by the diaphragm. These cells are filled with the electrolyte (sodium or potassium hydroxide), which acts as a conductor, connecting up the plates in series.

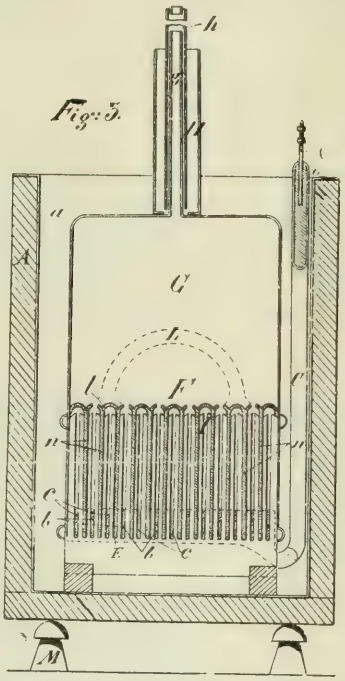

FIG. 3. GARUTI GENERATOR—VERTICAL CROSS-SECTION

An electric current admitted at one end plate passes on through the plates and through the solution to the other end plate. In its passage, it decomposes the water of the solution into the two gases —hydrogen and oxygen —which are released on opposite sides of each plate and emerge upward into the gas offtakes. The mingling of the hydrogen and oxygen in each cell or compartment is prevented by the diaphragm which, while permitting the passage of the fluid, resists the passage of the gases.

FIG. 4. GARUTI GENERATOR — PLAN VIEW OF CONDUCTORS AND ELECTRODES

The electrodes *C* are clamped together by a heavy screw *D* working in the rear support. The surfaces of the electrodes carry vertical corrugations which are interrupted by a large number of depressions to facilitate the flow of electrolyte into the cell and the release of the gases from it.

At top and bottom of each electrode are two openings communicating by cored channels with opposite sides of the plate. Those at the bottom are for the water intakes and those at the top are for the gas offtakes. It will be seen that each half has its own independent water intake and gas outlet, so that there can be no possibility of the two gases mingling through these channels.

[1] U. S. Patent 629,070, July 18, 1899.

[2] Met. & Chem. Eng., vol. 14, p. 108, Jan. 15, 1916.

The diaphragms *H* are of specially prepared asbestos fabric. All around the edge of this fabric is molded a packing rim *G* of pure rubber which is an integral part of the diaphragm and which rests in a recessed groove on the face of the electrode.

Obviously, in a generator of this type, an essential of power economy is that all the current supplied shall pass through the electrolyte and none of it be bypassed through the metal of the generator or through the water inlets and gas outlets, therefore the electrodes are insulated from the side bars of the frames by porcelain insulators *E* resting on a wooden base. They are insulated from one another by the rubber packing rim *G* surrounding the diaphragm and by rubber nipples inserted in the water intake and gas offtake shoulders of the electrodes, which also provide an insulating tube in the interior of the water intake and gas offtakes.

At the front of the cells and elevated above the electrodes is a solution box or tank *B* which receives the distilled water that is supplied to the electrode chambers or cells *C*. From this tank a pipe descends to a water-feed manifold, the latter branching to two independent connections to the two separate water intakes to the cells. And from this manifold two risers lead, one to each of the two gas domes *AA* above.

Into these gas domes the hydrogen and oxygen are separately introduced as generated. The arrangement is such that a constant fluid level between the electrodes is automatically maintained. The description will apply to all filter press type cells.

As the individual resistances are in series, the number of plates in the unit determines the actual voltage necessary. The voltage drop per plate is 2.4 to 2.5 when using a 28.9 per cent solution of sodium hydroxide. The average current density is about 20 to 30 amp. per sq.ft. and the production is 7.5 cu.ft. of hydrogen and 3.75 cu.ft. of oxygen per kw.-hr. measured at 20 deg. C. and 760 mm. pressure. The purity of the gases averages between 99.1 and 99.5 per cent for the hydrogen and 98.7 per cent for the oxygen.

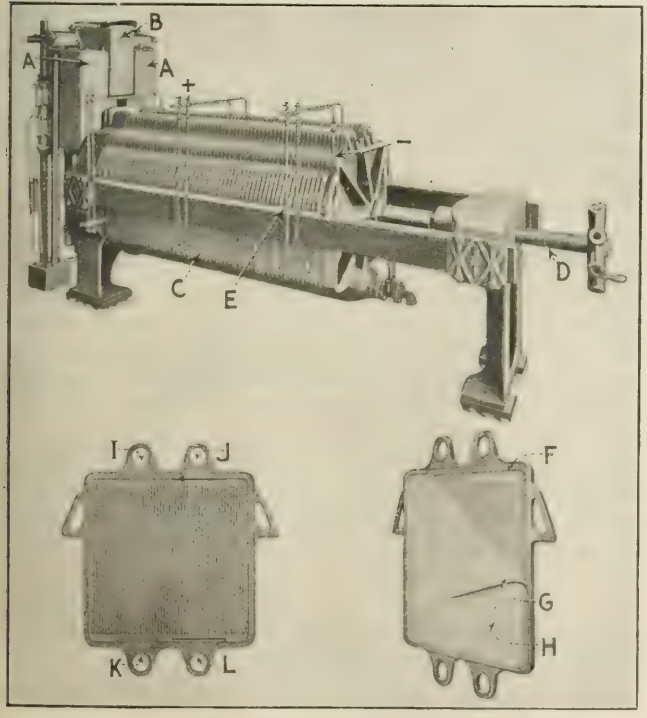

FIG. 5. FILTER PRESS OR BI-POLAR TYPE CELL
Above—Cell completely assembled. Lower left—Electrode from anode side, showing water intake and gas offtake channels and corrugations. Lower right—Electrode with diaphragm partly removed, showing method of holding and packing the diaphragm.

The filter press type of cell is compact, but is offset by other disadvantages. Water and gas tightness in the individual cell depends upon the rubber in the diaphragms and on contraction and expansion. This type of cell requires constant overhauling. The suspended diaphram tank type cell, as illustrated by the diagrammatic drawing (Fig. 6), consists of an oblong tank *G* made of mild sheet steel with flanges at the top standing on insulators *H*. In this tank an oblong diaphragm with curved ends and bottom *L*, perforated with oblong holes, is suspended from the thick steel lid of the cell *O*, by means of hollow electrodes *D*. An asbestos sack *K* surrounds the diaphragm *L*, which forms a partition between the side of the tank *G* and also the metal partition *M*. The asbestos sack is held by a fixture band *J* on the non-conducting separator *I*.

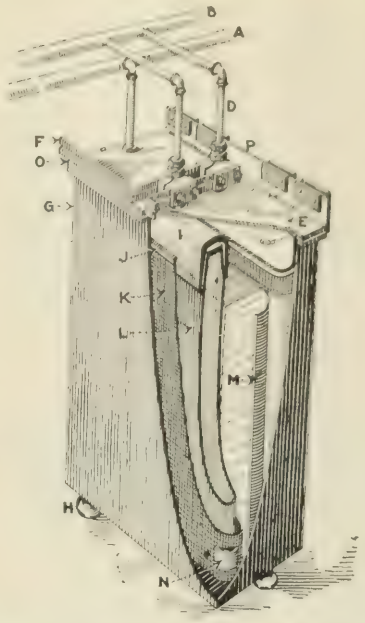

FIG. 6. SUSPENDED DIAPHRAGM TANK TYPE CELL

Either one or two diaphragms may be used in this type cell. In the diagrammatic sketch a partial view of one diaphragm is seen with a partition of mild sheet steel *M* which separates the other diaphragm (not seen in the sketch).

The lid *O* is insulated and bolted down on the flanged top of the tank. To this lid is attached the filling cup *E*, gas outlet pipes *A* and *B* and positive busbar *F*. The negative busbar *P* is attached to the side of the tank and extends above the lid.

The interior of the tank is filled to within about 10 in. of the cover with a 15 per cent solution of sodium hydroxide in distilled water.

The mode of operation of the cell is as follows: If the positive lead of the circuit is connected to busbar *F*, and the negative lead is connected to busbar *P*, electrolysis will take place and hydrogen will be liberated on the side of the tank *G*, rising through the electrolyte, where it is free to circulate to the outlet pipe *A*. While hydrogen is being liberated on the sides of the tank *G* and partition *M* oxygen will be liberated on both sides of the diaphragm *L*, from where it will rise up and pass out of pipe *DD*. In each of the four corners of the asbestos sack is a pocket *N*, which holds an insulator which permits on the outside diaphragm *L* the free circulation of oxygen bubbles by expanding the sack slightly. Distilled water is added to the filling cup *E* from time to time, to replace that decomposed by the current. The voltage drop between anode and cathode is 2.2 volts. The purity of hydrogen is above 99½ per cent and that of the oxygen above 99 per cent. The suspended diaphragm tank cell has been one of the most successful types of cell developed.

An example of the non-porous non-conducting diaphram

type is represented in the Schoop cell (Fig. 7) in which an acid electrolyte is used. The electrolyzer consists of a cylindrical lead-lined tank containing four vertical electrodes. These are in the form of lead tubes filled with fine lead wire to increase active electrode surface. Each electrode is surrounded by a cylindrical tube of glass or porcelain—open below and perforated at the bottom to allow the flow of current. The gas generated on the electrode within the glass or porcelain tube passes upward, where it is collected. Where an alkaline solution is employed the tank and electrodes are made of iron.

Hydrogen as Byproduct From Electrolytic Chlorine Cells

Some electrolytic cells designed for the manufacture of products other than those already discussed yield hydrogen as a byproduct, i.e., those used in the electrolytic process for the manufacture of caustic soda.

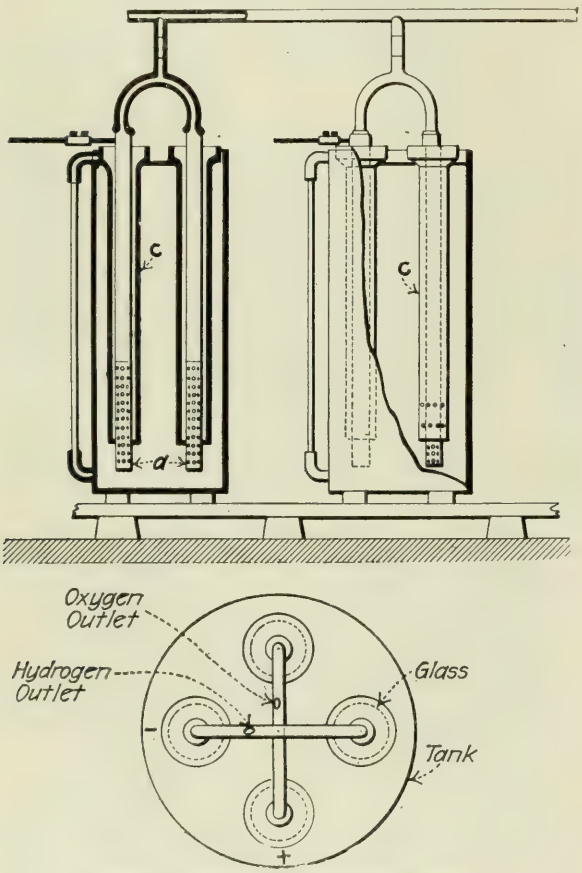

FIG. 7. SCHOOP ELECTROLYZER

The Castner mercury cell (Fig. 8) is probably the most important type of cell yielding hydrogen as a byproduct. The function of this cell is primarily the production of caustic soda and chlorine from a solution of brine, but at the same time hydrogen is produced.

The cell is divided into three compartments by vertical partitions extending almost to the bottom of the cell, but not making a tight joint therewith. In the two end compartments *A* and *C* is placed a strong solution of brine, while the middle compartment *B* is filled with water. The current, in flowing through the cell, passes from the positive carbon *DD* through the brine, thence to the mercury and from the mercury to the negative electrode *E* in the center compartment. By the splitting up of the sodium chloride in the end compartments, chlorine will be liberated at the positive electrode and passes out at *F*, while sodium will be deposited on the mercury, forming sodium mercury amalgam.

This amalgam is transferred to the central compartment by a slow rocking motion which is given the cell by the eccentric *G* and is decomposed at the negative

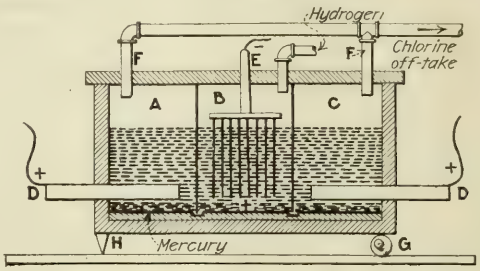

FIG. 8. CASTNER CAUSTIC SODA-CHLORINE CELL

electrode in accordance with the following equation:

$$2Na + 2H_2O = 2NaOH + H_2$$

It will be seen that the net results of the process are that chlorine is produced in the end compartment, and caustic soda and hydrogen in *B*, the center one. The hydrogen usually contains a certain percentage of chlorine which is detrimental.

German Dyes in Java and Their American Competitors

Agents in Holland for German dye manufacturers are circularizing the consumers and dealers in the Dutch East Indies to the effect that they are now in a position to obtain German dyes, but that the prices have greatly increased over the pre-war figures, and give one instance of a color which before the war sold at 1 guilder per gram and is now quoted at 100 guilders.

Java is an important market for dyes, and some of the importers who sold German dyes in pre-war days are now agents for American dye manufacturers. These importers are much encouraged regarding the outlook for the American product, but the American industry is so young on this market that there are points in the dyeing processes of many of the colors that will have to be more fully developed before they are suitable for the native trade, which is the big trade here.

American dye manufacturers should not lean too strongly on the efforts of their agents in Java to sell their product. This is no reflection on the importers, as they are well equipped for selling and distributing, but there is plenty of work still to be done on the technical side of the business to warrant the presence in Java of a practical dye chemist. The importer has not the technical knowledge to do this work, and if it is left to him progress will be slow.

If the German manufacturers are in a position where their prices will have to go up in a fraction of the degree indicated above, it would seem that there is a present opportunity for American dyes to get a very strong place in this trade.

Commissioner to Study South American Market for Industrial Supplies

Philip S. Smith of Schenectady has been appointed trade commissioner to study South American markets for industrial supplies. Mr. Smith has previously reported on markets for electrical goods in Latin America and in Spain.

Dust Exhaust System at Arizona Copper Co. Mill

By M. R. Hull

THE ore which reaches the crushing department of the Arizona Copper Co.'s Morenci Mill carrying 3.85 per cent moisture is crushed dry from run-of-mine size to ¾ in. at the rate of about 250 tons per hr. Fig. 1 shows the crushing plant flow sheet. An equipment for removing dust, for the purpose of improving the working conditions in this plant, was installed in 1917.

Dust Exhaust Hoods

A careful study of the plant previous to designing the exhaust system showed that, with a small amount of judicious housing, the dust could be effectively drawn from seven hoods. These hoods were placed as follows:

Number of Hoods	Location	Size of Hood	Dia. of Branch Pipe, In.
1	Over gyratory crusher.....	5 ft. 6 in. x 5 ft. 6 in.	10
2	At discharge of 24-in. conveyor...	2 ft. 6 in. x 3 ft.	8
2	At discharge of disk crushers onto 26-in. belt conveyor.....	2 ft. 6 in. x 2 ft. 8 in.	8
2	At discharge of 26-in. belt conveyors into feed chute of 54-in. rolls.....	2 ft. x 3 ft.	8

Fig. 2 shows the construction above the gyratory crusher. Near all machines, flanged connections of hoods and pipes were used to facilitate their removal, thereby rendering the machines easily accessible for inspection and repairs.

Details of Construction

Proportioning of Piping. In every case the area of the main is slightly larger than the combined area of all branches discharging into it.

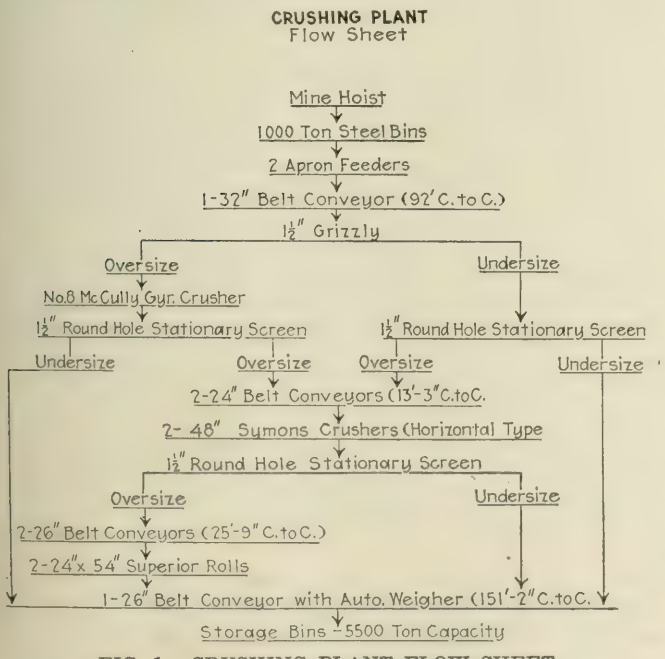

FIG. 1. CRUSHING PLANT FLOW SHEET

Velocity of Air. All branch pipes were proportioned for a velocity of air of 4,000 lin.ft. per min., and the power consumed in operation indicates that this velocity is about 4,200 ft. under operating conditions.

Hoods. In all cases where possible the hoods were so made that the area of the net air opening into the hood does not exceed the area of the exhaust pipe leading from the hood, and the hood so placed that the dust is naturally thrown toward its apex. These conditions are essential to successful operation.

Piping—Bends. No bends, where clearances permit, have a radius of less than $a = 1\frac{1}{2}d$, where a = radius of center line of pipe and d = diameter of pipe, but tests on other air pipes have shown that there is no advantage in making a greater than $2d$.

Intersections. No branches intersect the main pipe at an angle greater than 45 deg.

Laps. All the laps are in the direction to cause least resistance to flow of air.

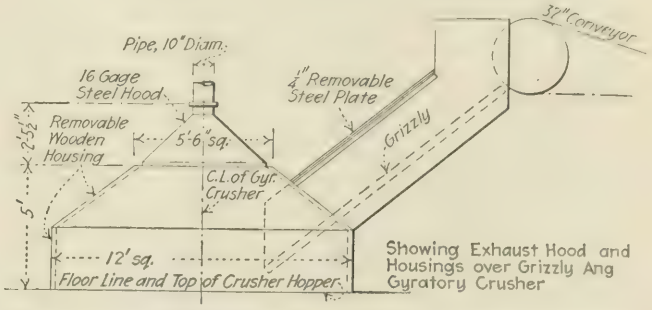

FIG. 2. CONSTRUCTION ABOVE GYRATORY CRUSHER

Joints. All the joints are riveted and soldered, except where flanged joints are required for easy removal.

Thickness of Metal. All straight pipe is made of No. 20 gage galvanized steel. Some of the bends showed considerable wear after 15 months' operation and should have been made of No. 16 gage. All the hoods are of No. 16 gage galvanized steel.

The Collector

The collector is a modification of the well-known cyclone type depending upon centrifugal action to bring the dust particles into contact with the inside cylindrical surface, which is sprayed with water. The dust is thereby arrested and is also washed down the sides, where it accumulates as a thin pulp in a concrete basin. This basin serves also as a foundation for the collector.

The lower part of the collector is cylindrical instead of conical, as they are usually made, to eliminate all chance of the solids adhering to the sides. The center pipe was made with an adjustable sleeve, as it was intended to determine by test the efficiency of the collector and power consumption for various adjustments of this sleeve, and to dispense with it if it proved unnecessary. This test I think has not been made.

Fig. 3 shows the essentials of its construction, an interesting feature of which is the discharge trap which was designed to maintain a suction on the fan of from 5¼ in. to 10 in. head of water. The adjustment is made by raising or lowering the level of the discharge weir by means of wooden strips 2 in. wide x 9 in. long. The fan is operating under a suction of about 6 in. of water.

Exhaust Fan

The exhaust fan is a Sturtevant slow speed planing mill exhauster No. 70 of 20,000 cu.ft. per min. capacity and 4 oz. pressure when running at 545 r.p.m. It is running 577 r.p.m. and by calculation is delivering about 11,000 cu.ft. per min. at about 3½ oz. pressure.

The fan was selected and the collector designed to provide for extending the suction system. The fan is located beyond the collector with the "draw through"

system, the fan exhausting the air from which the dust has been separated directly into the atmosphere.

Remarks and Conclusions

Operating data obtained by tests extending over a period of nine days show average results:

Tons of ore crushed per hour	237
Moisture in ore, per cent	3.85
Tons dry dust collected per hour	0.087
Per cent dust collected as per cent ore crushed	0.0367
Gallons of water per hour	570
Gallons of water per ton dust collected	6,552
Per cent copper in ore	.....
Per cent copper in dust	2.34
Horsepower input to fan motor	23
Cu. ft. of air per minute discharged by fan*	11,100
Velocity in suction pipes, ft. per min*	4,200

* Calculated from hp. absorbed by motor, allowing 90 per cent efficiency for motor and 50 per cent efficiency for fan.

Except for the weight of metal in pipe bends, no criticism of this installation either in construction or

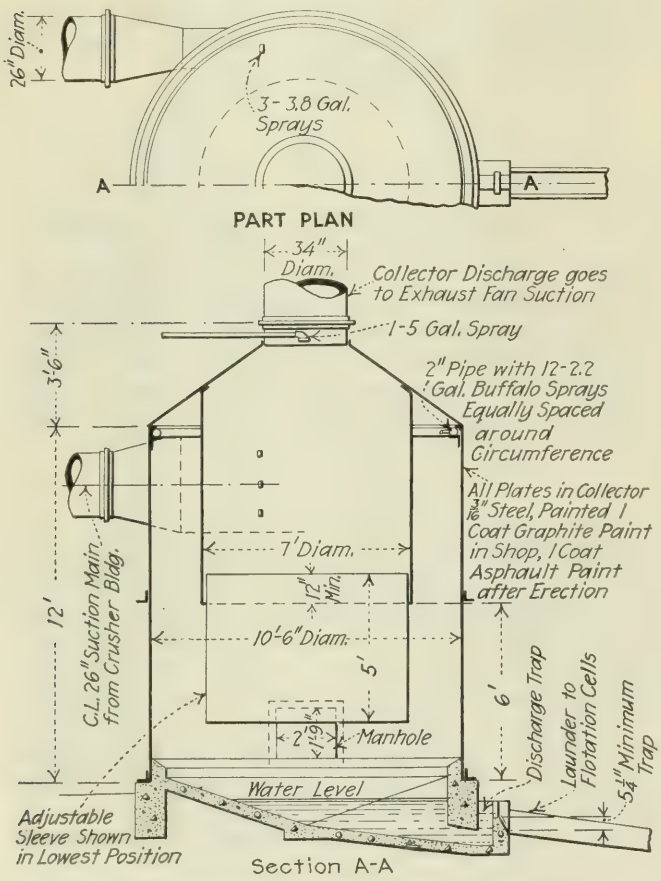

FIG. 3. CONSTRUCTION OF THE COLLECTOR

operation has been made by the operating department.

When it was placed in operation, all complaints from the operators as to dust were ended. It requires practically no attention other than the oiling of the motor and fan bearings.

The amount of water used is in excess of requirements, but no experiments have been made to determine the minimum amount required.

The advantages of the installation are:

(*a*) Improvement in working conditions.

(*b*) A saving of power and wear on mechanical equipment of the crushing plant due to removal of dust.

(*c*) Saving of labor formerly necessary to remove dust from building and equipment.

(*d*) Saving the values formerly lost in the dust. This alone is probably sufficient to pay for the cost of operating the exhaust system.

History of Asbestos Paper*

By Oliver Bowles

THE asbestos used by the ancients, termed amiantus by Pliny, was used for winding sheets, tablecloths and other fabrics. It was probably chrysotile fiber and was a woven and not a felted product, and therefore is not to be confused with asbestos paper. There are, however, some early references to paper manufacture that are of interest. Pontoppidian, Bishop of Bergen, in his Natural History of Norway, published in 1750, refers to paper made from asbestos found in the parish of Waldens. He states that this paper did not burn when thrown in the fire, but the writing on it totally disappeared. This indicates that the primary object was to obtain an indestructible writing paper. About 100 years later, further efforts were made with the same object in view.

In 1853, a patent was issued for a process making paper from a mixture of asbestos and alum. Many experiments were made to manufacture suitable asbestos printing paper. Some such papers contained only about one-third asbestos, the remainder being of combustible material. Such papers would burn, but would leave a white residue which retained its shape and preserved the written characters. On account of the difficulty of obtaining a smooth and even surface, and the tendency for the material to absorb ink like blotting paper, asbestos paper is not well adapted for writing or printing purposes.

Other early uses of asbestos paper were for ornamental wall-paper and carpet linings. None of the uses mentioned have developed to anything of importance in a practical way, but the manufacture of asbestos paper has become a very important industry in the past twenty-five years, and it has found extensive uses in ways that were never dreamed of by the early investigators.

It is recorded that the first sheet of asbestos paper made in America was manufactured in 1876 by John Roberts & Son Co., in a mill near Waltham, Mass. The material first used was a long-fibered amphibole asbestos from Italy. About three years later, Canadian fiber was introduced and proved to be very satisfactory. The shorter grades of fiber which would otherwise be wasted were used for the manufacture of paper and board. From 1881 to 1900, the H. W. Johns Co. of New York took the entire product, which was 300 to 700 tons per year. The latter company built its own asbestos paper mill at Brooklyn in 1900. The Keasbey & Mattison Co. of Ambler, Pa., began to manufacture in 1897. Other early manufacturers were: the Asbestos Paper Co., at Baldwinsville, Mass., and B. S. Binney, at Shirley, Mass. The number of manufacturers gradually increased until at present asbestos paper is manufactured by ten companies.

It is interesting to note that the pioneers, John Roberts & Son Co. still manufacture asbestos paper, the present output being about 1,200 tons per year.

Production has made tremendous strides, some plants manufacturing as much paper in a day as was made in an entire year twenty-five years ago. The average production for the past two or three years has been about 25,000 to 30,000 tons per year. During the war the demand was small, and it is still much below normal. Present plant capacity is, therefore, very much greater

*Abstracts from monthly reports on investigations, Bureau of Mines, November, 1919.

than the above figures would indicate. The present price of asbestos paper is $10 to $15 per cwt.

Manufacturers of asbestos paper also manufacture other pulp products, such as mill-board, which is made in various thicknesses. The chief uses of asbestos paper and mill-board are as follows: For high pressure gaskets and packings, insulations, lining for stoves, air-cell pipe covering, roofing, building paper, and other uses in the building trades. On account of its resistance to fire and high temperature, and its insulating properties, asbestos paper occupies an important place in modern industry.

Use of Spiegeleisen in Steel Manufacture*

By Henry D. Hibbard

SPIEGELEISEN was the first manganese alloy employed, about sixty years ago, for deoxidizing steel made by the bessemer process and later in 1865 for steel made by the Martin process, carried out in the Siemens furnace and now known as the open-hearth process. The name spiegeleisen was that of a white manganiferous pig iron made in Prussia containing from 7 to 8 per cent of manganese. Irons richer in manganese were made from time to time in the years which followed as they were found to be desirable, but the same name—contracted to "spiegel" in the shop—was applied to all such irons up to those containing over 20 per cent of manganese, to which the name of ferromanganese was given when they were first made, about 1870. As time went on richer and richer manganese alloys were made, all of which were called ferromanganese, until our present standard alloy of 80 per cent came into general use in 1880. As ferromanganese became richer in manganese, so did the irons included under the name of spiegel, and now the dividing line between spiegel and ferromanganese may be fairly taken at 40 per cent, all richer alloys being called ferromanganese and all of 40 per cent or less being called spiegel. This is the sense in which the names are used throughout this statement.

Use of Ferromanganese

The advantages of a more condensed form of manganese, because of which ferromanganese became the popular and almost universal form for adding the element to the molten metal in the oxidation processes, lie in the smaller weight to be handled, which renders preheating and pre-melting unnecessary, while at prewar prices it is perhaps the cheapest form of manganese as well. It is brittle, enabling it to be easily broken to size when desired. Then for soft or low carbon steel there is the important additional advantage of its high ratio of manganese to carbon, about 12 to 1, which favors greatly the making of such steels, in that the carbon content can be kept down while an ample amount of manganese is added. When more carbon is needed in the harder steels than the ferromanganese contains it is provided by adding pig iron, or molten crude iron, or carbon in the form of coke or coal.

There has never been a doubt as to the suitability of spiegel for making the higher carbon steels of good quality. Its use requires no particular care, provided that it be melted or heated so as not to cool the metal beyond a permissible amount. When it was supplanted it was for the reasons already given.

It is also being used for the softer low-carbon steels. In practice which we have observed (mentioned below, under the caption "Example A") this is described and difficulties which were encountered are discussed.

Spiegel Practice

Example A. For two years a certain company has used exclusively in its basic open-hearth and bessemer practice spiegel produced from domestic ores. It has the average analysis given below:

	Per Cent		Per Cent
Manganese	31.25	Carbon	4.80
Iron	62.25	Silicon	1.43

In the open-hearth, soft-, medium- and high-carbon steel is produced. The spiegel is added cold. For high-carbon steel three-quarters is added to the bath about 20 min. before tapping and the remainder to the ladle. For low-carbon steels about half is added to the bath 10 min. before tapping and the other half to the ladle. The manganese in the finished steel is from 50 to 70 per cent by weight of that added. The product is fairly free from red shortness, but the effect on the low-carbon steel is somewhat different from that usually obtained by the use of ferromanganese. It rose in the molds before "rimming in"; the ingots were too "thin skinned," the skin holes being too near the surface, so that some of them were opened up in the heating and rolling, causing tears, seams, streaks, pits, and scabs in the bloom or plate into which they were rolled. Whether this was due to the use of spiegel, or to too high silicon contained, or to some other reason, is uncertain. It is indeed possible and perhaps probable that methods might be found or developed which would give non-rising low-carbon steel with the use of spiegel, but to settle that question weeks or perhaps months might be required. This company is installing cupolas for melting the spiegel before adding it to the metal.

In the bessemer practice of this company the spiegel is broken to pieces the size of a hen's egg and smaller, heated to redness, and added in the ladle as the charge is poured from the converter. Only soft steel is made, containing about 0.08 per cent carbon. The heats observed all rose in the mold before "rimming in," in like manner to the open-hearth steel, although to a lesser degree. The steel, when bloomed, showed defects like those of the open-hearth steel mentioned above.

Example B. A spiegel "mixture" has been used exclusively by another company for a number of years for steels containing over 0.30 per cent carbon. The alloy is added molten. A mixture of standard 20 per cent spiegel, pig iron and, in some cases, ferrosilicon is made up, so that the molten alloy will exactly satisfy the requirements of the steel for carbon, silicon and manganese. The carbon in the bath is worked down to 0.15 per cent and the residual manganese averages 0.17 per cent in tapping out time. The following examples show the percentages of manganese used in spiegel mixtures:

Finished Steel			Bath Metal		Spiegel Mixture		
% C	% Mn	% Si	% C	% Mn	% C	% Mn	% Si
0.68	0.75	0.13	0.15	0.17	4.2	6.50	1.60
0.39	0.62	0.17	0.15	0.27	4.3	9.00	4.25

The manganese loss in the cupola and ladle is 30 per cent by weight.

*Abstracts of a report submitted to the director of the Bureau of Mines, Jan. 7, 1918, and withheld from publication at that time because of its confidential character. While primarily an estimate of requirements for 1918, the data on which this estimate is based are of much general interest, and were issued in November, 1919, in the Monthly Reports of Investigations, Bureau of Mines.

The finished steel is fairly uniform in quality, and for steel above 0.30 per cent carbon this company considers it the most effective method of adding manganese. Test samples of finished steel are taken after pouring the first ingot and again near the end of the teeming. These samples are almost identical in manganese and other constituents. This company claims to be the first to use molten spiegel in open-hearth steel, but several other plants are now using it in the same way.

It seems at least possible that steel lower than 0.30 per cent carbon may be satisfactorily made by means of this practice by using a higher manganese spiegel mixture. On the basis of the method used by this company for computing their mixture, the following table has been prepared to show how, from the chemical standpoint, steel containing 0.20 per cent carbon can be made from various spiegel mixtures:

% C in Bath	Lb. Alloy per Ton of Steel	% Mn in Alloy	% Loss Mn Cupola and Ladle	% Carbon in Alloy
0.08	56.0	18.85	30	4.8
0.10	43.2	25.60	33	5.2
0.12	32.5	36.10	37	5.5
0.15	18.7	66.0	40	6.0

From this table, it is evident that with the use of a 66 per cent mixture the heats could be tapped at 0.15 per cent carbon. If carbon were 0.10 per cent at tapping a 25.60 per cent manganese mixture could be used. It would, of course, take somewhat longer to work the carbon down from 0.15 to 0.10 per cent, and the output of a given furnace per day would be decreased proportionately.

Estimated Tonnage of Steel in 1918 for Which Spiegel Can Be Used

The table below gives the estimated steel ingots and castings in 1918, and the tonnage which may be recarburized with spiegel. This estimate is based on the assumption that there will not be a large total increase, because there will not be the fuel available.

ESTIMATED STEEL INGOTS AND CASTINGS IN 1918

	Long Tons	Tonnage Which May Be Recarburized with Spiegel
Rails	3,400,000	3,400,000
Plates and sheets	10,700,000	1,400,000
Nail and spike plate	30,000	30,000
Wire rods	4,000,000	3,000,000
Structural shapes	3,200,000	3,200,000
Merchant bars	9,150,000	8,000,000
Bars (concrete)	450,000	250,000
Skelp	3,150,000	150,000
Splice bars	575,000	575,000
Hoops	285,000	285,000
Bands and cotton ties	570,000	570,000
Rolled sheet piling	17,000	17,000
Railroad ties	40,000	40,000
Rolled forging billets	5,150,000	4,000,000
Blooms, billets, etc	570,000	400,000
Miscellaneous rolled	1,250,000	700,000
Castings	1,500,000	1,000,000
Total	44,037,000	27,017,000

Using spiegeleisen instead of ferromanganese is entirely feasible for about 70 per cent of the steel manufactured in the United States at the present time. Its practicability for the classes of steel enumerated below is not yet demonstrated to satisfaction:

Ingots for plates and the better quality sheets, and for pipe.

Other low-carbon steel requiring extra fine surface.

Steel below 0.10 per cent carbon.

Steel castings made by the converter process where plants are not equipped with crucible or cupola furnaces for melting recarburizers.

The above estimate is made on the assumption that spiegel will be available, if necessary, containing between 20 and 30 per cent manganese.

Estimated Tonnage of Spiegeleisen Required in the Year 1918

On the basis of the estimate of 27,000,000 tons of steel and assuming 14.9 lb. of metallic manganese required per ton, 180,000 tons of metallic manganese must be supplied in the form of spiegel. With an average content of 25 per cent manganese, 720,000 tons of spiegel would be required. For the production of this amount, there would be required about 1,620,000 tons of manganiferous iron ore of the following analysis:

	Per Cent
Manganese	17.50
Iron	32.50
Silicon	12.00

Probably spiegels will be made containing respectively from 10 to 40 per cent of manganese for which proportionate amounts of ores of suitable compositions would be required.

Estimated Tonnage of 80 Per Cent Ferromanganese Required in the Year 1918

By deducting from the estimated total production of the year 1918 the tonnage that may be recarburized with spiegel, there remain 17,000,000 tons of steel ingots and castings which it is not yet demonstrated can be successfully recarburized with spiegel. Assuming 9 lb. of metallic manganese per ton, equivalent to 11.25 lb. of 80 per cent ferromanganese per ton, then 85,000 tons of 80 per cent ferromanganese is the amount proper for recarburizing 17,000,000 tons of steel. The percentage of manganese added to soft steel is substantially lower than added to high carbon steels. The average for all steels made is now about 13 lb. per ton.

For the manufacture of manganese steel, estimated to be about 70,000 tons of steel in ladle, 10,000 tons of ferromanganese will be needed. This, with the 85,000 tons previously mentioned, makes a total of 95,000 tons.

This quantity will probably require about 250,000 tons of manganese ore for its production.

Canadian Chemical Exports

Exports of chemicals and chemical products from Canada fell off decidedly during the seven months ended October, 1919, as compared with the corresponding period of 1918. The total chemical exports for the first seven months of the current year were $12,817,907; the exports for the similar period of the previous year were $36,050,250.

The exportation of non-metallic minerals and products, however, showed a slight increase for the seven months ended October, 1919, the aggregate value of such exports having been $14,037,723, as against $13,777,252 for the seven months ended October, 1918. Exports of ores, metals and metal manufactures other than iron and steel for the same period amounted to $28,288,774 in 1919, and $47,015,270 in 1918.

Imports of chemicals and chemical products and non-metallic minerals showed slight decreases during the month of October, 1919, as compared with the same month of 1918.

Canadian trade as a whole, both imports and exports, increased measurably during the month of October over the previous month of 1919. The total exports amounted to $201,357,291, while the total imports amounted to $91,910,477, for October, 1919.

The Heat Treatment of Beta Brasses

A Study of the Relation Between Various Physical Properties of Beta Brasses as the Annealing and Quenching Temperature Varies — Methods of Procuring Strong, Ductile Pieces Are Described

By H. M. BRAYTON

THE writer while a senior student at the Massachusetts Institute of Technology conducted a lengthy investigation on "The Heat Treatment of Beta Brasses," under supervision of Prof. Henry Fay.[1] Very little scientific data seem to be available on this subject. Such investigative work as has been done by the various brass companies seems to have failed to find its way into the current press or to the public in book form. In order to understand the whole subject better it will be necessary to give here an outline of work thus far done by other investigators in the same field.

Broadly speaking, what data we have available on other compositions seem to have come largely through the efforts of English and Continental scientists. More attention has apparently been given to the development of the practical side in America than to the purely scientific aspect. Such men as Charpy and Le Chatelier in France, Stead, Stedman, Hudson, Austin and Bengough in England have conducted valuable researches in the 70-30 region. Their results have been published from time to time in the *Journal* of the Institute of Metals.

The following is a brief abstract from a paper by Stead and Stedman[2] on their researches into the relations between the heat treatment and mechanical properties of Muntz metal.[3] Tests were made on half-inch round stock of cold-drawn brass. The specimens were kept at a constant temperature for 48 hr. At the end of this time some were quenched in cold water and some were cooled slowly in air. A few of the specimens were kept in a gas flue at a temperature between 430 and 450 deg. C. for three months. The following results were obtained from the experiments:

1. The most ductile cold-drawn Muntz metal is obtained by annealing at 430 deg. C. for three months. It is obvious, however, that such a treatment is not practical commercially.
2. The Brinell hardness increases as the temperature of quenching increases.
3. There is a critical temperature near 750 deg. C. The metal becomes ductile again at higher temperatures.
4. It is dangerous to anneal between 750 and 800 deg. C. because the beta crystals are liable to become enveloped with the alpha constituent. This structural arrangement is conducive to weakness in both chilled and air-cooled brasses.
5. Heating to 800 deg. C. followed by quenching gives homogeneous beta constituent, and a tensile strength of 58,000 lb. per sq.in. Heating to 500 deg. C. followed by quenching reduces the tensile strength to 52,000 lb. per sq.in.
6. Brass is very immune from oxidation during heating. The loss is only 0.8 per cent in 48 hr. at a temperature of 860 deg. C.

Bengough and Hudson[4] published the results of their study on brass of the 70-30 composition which contained 0.2 per cent of lead and 0.15 per cent of tin. The specimens were kept at the required temperature for 50 minutes and cooled in air. Their results are as follows:

1. Heating to 275 deg. C. has no effect on the breaking load.
2. From 275 to 300 deg. C. the breaking load fell off rapidly.
3. From 300 to 900 deg. C. the breaking load fell off more slowly.
4. Temperatures up to 250 deg. had no effect on the ductility.
5. From 275 to 300 deg. C. the elongation rapidly increased.
6. From 300 to 825 deg. C. a regular increase in the elongation was observed.
7. Above 825 deg. C. the elongation decreased.
8. Impurities in brass have the effect of causing it to burn at a lower temperature.

Messrs. Babson and Buhler, two students at Massachusetts Institute of Technology, conducted a series of experiments in 1903 on "The Effects That Different Temperatures of Annealing Have on the Physical Properties of Brass and the Effects of Different Gases at Annealing Temperatures on the Microstructure of Brass." These experimenters worked on the following compositions:

Alloy	Per Cent Cu	Per Cent Zn	Per Cent Pb	Per Cent Sb
No. 1	62.91	34.50	2.64	Trace
No. 2	63.37	33.87	2.69	Trace
No. 3	63.23	34.02	2.61	Trace

Eighteen-inch specimens were cut from ¾-in. round stock and held at the various temperatures for 2 hr., and air cooled with the following results:

1. Tensile strength varies inversely with the temperature of annealing.
2. Percentage elongation is practically constant at temperatures below 340 deg. C.
3. At 420 deg. C. there is a marked decrease in percentage elongation.
4. Maximum elongation takes place at 450 deg. C.

It would appear from these results that there must be an important change of structure between 340 and 450 deg. C.

Recently an excellent article on metallic alloys[5] dealing principally with brass and bronze appeared, copiously illustrated with microphotographs.

Materials Used in the Present Investigation

The series of experiments described below were conducted on material furnished by the American Brass Co., Waterbury, Conn. After drawing to $\frac{1}{2}\frac{5}{2}$ in. the

[1]The writer wishes to acknowledge Dr. Fay's part in the work at this time. The satisfactory completion of the investigation and the knowledge obtained were made possible only by his excellent supervision. Special acknowledgment is also due Prof. Harrison W. Hayward for his careful supervision of mechanical details and arrangement of apparatus. Finally to I. H. Cowdrey, also of the Institute staff, the writer wishes to express his appreciation for the many helpful suggestions during the actual tests.

rods had been annealed, and then cold drawn through a ½-in. die.

Two alloys were furnished which were analyzed:

Alloy	Per Cent Cu	Per Cent Zn	Per Cent Pb	Per Cent Sn
A	60.58	38.67	None	0.75
AA	56.17	41.24	2.53	0.06

Alloy A

This material came in the form of ½-in. round rods about 10 ft. long, finished and machine straightened. Five rods were received and marked 1, 2, 3, 4, and 5 in consecutive order as they came through the die.

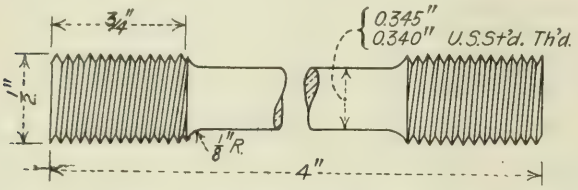

FIG. 1. DETAIL DRAWING OF SPECIMEN USED IN THE TESTS

This arrangement was important, as any variation in the physical properties of the metal as it came through the die had to be carefully considered.

The stock was cut into 4½-in. lengths and each specimen was carefully marked in order to keep track of its position throughout the run of metal. Specimens from alloy A were marked consecutively A1, A2, A3, etc., from the beginning of the run and in a similar manner alloy AA was marked AA1, AA2, AA3, etc.

Variations in Initial Properties of Alloy A

In order to study the variations in strength, ductility, elongation, etc., throughout the run of metal as it came from the die and in the natural or untreated state, five specimens from alloy A were selected and marked A1p, A2p, A3p, A4p, and A5p. These specimens were then made up into the standard tensile test piece shown in Fig. 1, broken in a small Riehle machine, with results as tabulated in Table I.

TABLE I. PHYSICAL PROPERTIES OF ALLOY A AS RECEIVED

AA2 pp	79,270	22.5	27.2	132	8
AA3 pp	78,680	22.5	27.8	124	8

This metal was, of course, all from the same heat and the variations are those due simply to the inaccuracies of manufacture of excellent quality material. The increase in strength of this alloy is very marked. Naturally the ductility decreases as the strength increases. The change in the reduction of area is the most marked. Hardness did not change perceptibly throughout the run of metal. This alloy showed good tendency toward "necking down" and gave ample warning before it finally ruptured. In each case a good clean partial cone break was produced. Due to this variation in the strength and ductility of the metal as received, any conclusions which have been later drawn on the effects of heat treatment in varying the physical properties of these alloys are based on careful consideration of the position of the specimen in the run of metal. Fig. 9 gives its microstructure; the crystals are badly deformed by the cold work.

Alloy AA

This material was received in the same form as alloy A and was prepared and marked in the same way. The untreated pieces were very brittle and each broke in the small punch mark used for obtaining elongation. The tests were therefore of little value. Due to this failure it was necessary to select three more specimens and these were marked AA1pp, AA2pp, AA3pp, to distinguish them from the first lot. These broke properly and the data obtained are shown tabulated in Table II. Tensile strength seemed to reach a maximum at the center of the run, but there is little actual variation. It might well be that if a large number of tests were run the average would be close to a straight line. In a like manner the reduction of area and elongation show but little variation throughout. In general the ductility seems to be about the same as for alloy A, the reduction of area being less and the elongation slightly more. The strength, on the other hand, is decidedly higher. The hardness of AA seems slightly greater than for A, but not as much as would be expected from the difference in tensile strength recorded; it is very brittle and broke with little warning, sometimes with a shearing break.

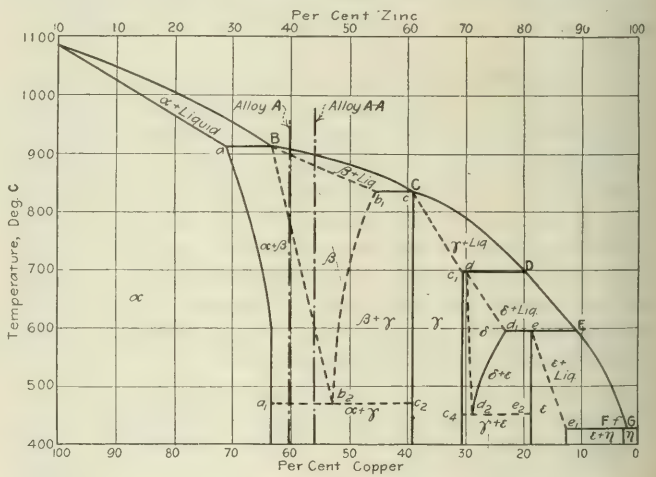

FIG. 2. EQUILIBRIUM DIAGRAM FOR COPPER-ZINC ALLOYS

Fig. 10 gives the original structure of AA, comparatively fine grained, and not badly distorted by the final draw.

Instrumental Equipment

An electric tube furnace with adjoining potentiometer was used in these experiments. An iron-iron constantan thermocouple was inserted in the furnace from the rear and packed with asbestos wool. Two specimens were then placed in the furnace from the front and the opening closed with a wad of the wool. These specimens were placed on an asbestos boat and a piece of iron wire wrapped about each one to facilitate rapid withdrawal

when being quenched. They were placed in the center of the furnace lengthwise and the thermocouple placed on the ridge of asbestos board between them. Temperature was regulated by means of a series resistance in the heating current.

The potentiometers used were Leeds & Northrup instruments, one a recorder, corrected against standard cells for cold junction temperature. A sensitive galvanometer in circuit made it possible to hold the temperature to a precision of 4 or 5 deg. F. The base

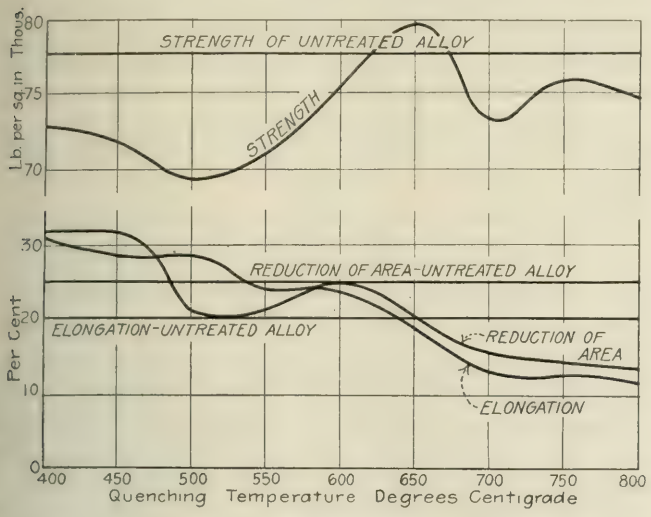

FIG. 3. PHYSICAL PROPERTIES OF QUENCHED SPECIMENS, ALLOY AA

metal couple used was first carefully calibrated against a standard platinum-platinum rhodium couple throughout the whole range of temperatures, and found to be accurate within the limits of precision required.

Effect of Time at 800 Deg. C.

A series of heat treatments were run on alloy AA to determine the effects on the physical properties and microstructure when varying the length of heating at 800 deg. C., followed by quenching. The main object

TABLE III. EFFECT OF TIME AT 800 DEG. C. ON ALLOY AA

Specimen	Hours at 800 Deg. C.	Ultimate Strength	Elongation	Reduction	Hardness — Brinell	Hardness — Scleroscope
AA1 pp	0	77,830	20.0	25.4	137	8
AA2 and 3	1	74,595	11.3	13.3	120	8
AA4 and 5	3	74,170	10.0	11.8	125	8
AA6 and 7	5	73,480	10.0	12.0	119	8

in this test was to determine if possible the length of time required at this temperature to convert the alloy into the beta state.

Three runs were made, check specimens being used in each case. About an hour was taken to reach the maximum temperature of 800 deg. C. When this temperature had been reached the furnace was held constant for 1 hr. in the first test and for 3 and 5 hr. respectively in each of the others, then the specimens were quenched in cold water, turned up into tensile pieces and broken in the Riehle machine. Table III shows the results obtained. Tensile strength falls off rapidly as the time of heating at this temperature is increased, due to two causes. At first it is due to the elimination of the effects of cold work which are present in the initial material; continual fall in strength is due to the rapid grain growth proceeding at high temperature, illustrated by microphotograph 14. A study of this and other photographs revealed that the brass was all in the beta state at the end of 3 hr. of heating. Some alpha crystals remained after the 1-hr. heating, and as a result of this study it was decided to conduct future heat treatments of 2 hr. duration.

It is customary in a study of metals to expect an increase in the ductility as the tensile strength falls off. This does not hold true here, as a very marked reduction in both the reduction of area and the per cent elongation took place as the time of heating at the high temperature was increased. The reason for this apparently lies in the very pronounced grain growth which took place.

Alloy AA was selected for these tests because it lies more nearly in the beta field of the copper-zinc equilibrium diagram shown in Fig. 2. The two alloys used in these experiments are shown on the diagram by the two vertical dash-dot lines. Alloy A lies largely in the $\alpha + \beta$ field and only enters the pure beta structure at high temperatures. The lead present in these alloys is added to better the machining qualities and as it forms only a mechanical mixture with the brass (note black spots in Fig. 13) does not affect the position of the alloy in the diagram. Tin forms a solid solution and for this reason it cannot be detected in the micrographs, while the percentage present is too small to affect the structure appreciably.

It will be interesting perhaps to stop a moment and study this equilibrium diagram. The α region com-

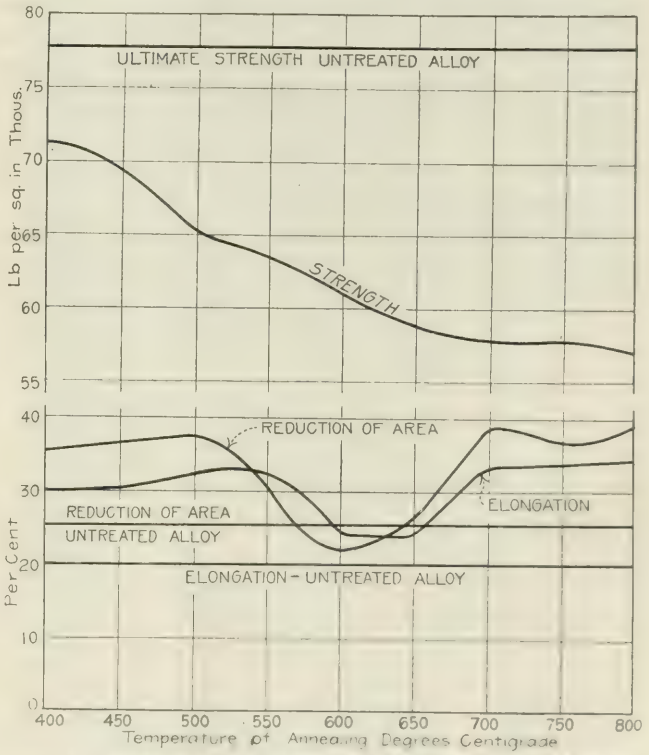

FIG. 4. PHYSICAL PROPERTIES OF FURNACE-COOLED SPECIMENS, ALLOY AA

prises a large portion to the left which represents a high percentage of copper. Alpha brass is soft and ductile—a composition of 70 per cent Cu with 30 per cent Zn is the one most commonly used in the arts. Heat treatment could not be expected to affect such a composition to a great extent because of the single structure extending to the liquid line; grain size would be the only thing changed. As the percentage of zinc increases the alloy becomes harder and the structure more

complicated. Alloys with zinc above 50 per cent are of but little use due to their extreme brittleness and low strength.

By referring to the equilibrium diagram it will be observed that alloy AA falls slightly to the left of the eutectoid point b_2 but still well within the beta region when heated above 600 deg. C. When at equilibrium at room temperature this material should consist of pure alpha crystals imbedded in a eutectoid matrix (alpha plus gamma complex). When heated to 470 deg. C. we should have a mixture of α plus β present and when heated still higher the whole field should consist of the beta structure. This last conclusion was found to be true when the specimens were heated to 800 deg. C. and quenched. This ideal condition does not always exist, as the time element enters in and may greatly affect the structure. Cooling needs to be very slow and heating carried out for some time in order to have these changes complete.

Quenching Alloy AA

It was desirable to find the physical properties of the various constituents throughout the various fields. Specimens were held for 2 hr. at various temperatures starting at 400 deg. C. and varying by 50 deg. increments up to 800 deg. C. At the end of this time the specimens were quickly withdrawn from the furnace and quenched in cold water. Check specimens were used in each case and the heat applied slowly, usually at the rate of 60 to 80 deg. rise every 5 min. It was not deemed advisable to carry the heat treatments above 800 because of the coarse structure formed and the danger of meeting the liquidus, which might well be lowered for this alloy by the tin content. Half an inch was cut from the end of each specimen for a microscopic study. Results obtained from the physical tests are given in curve form in Fig. 3.

This curve is of special interest because it shows how the strength of the alloy varies throughout the range of treatment. The strength drops off at low

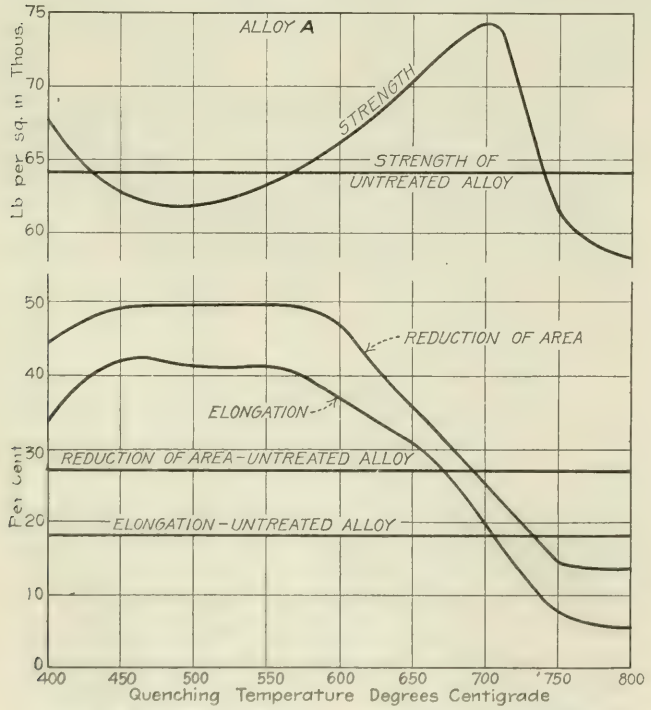

FIG. 5. PHYSICAL PROPERTIES OF QUENCHED SPECIMENS, ALLOY A

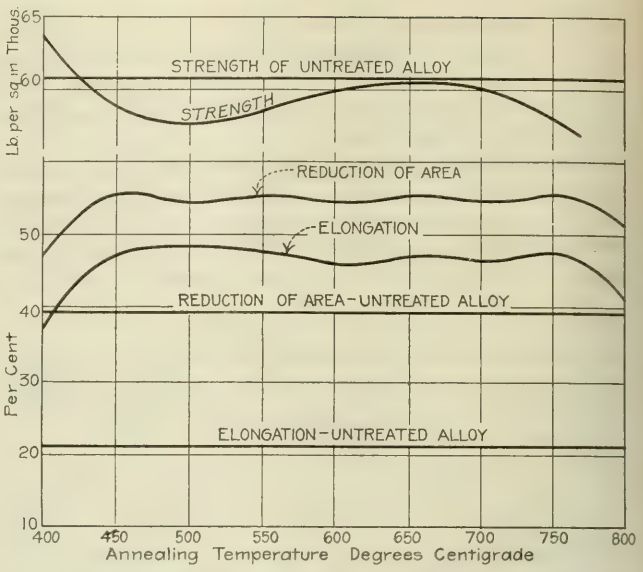

FIG. 6. PHYSICAL PROPERTIES OF ANNEALED SPECIMENS, ALLOY A

temperature anneal, which shows internal strains in the original rolled material. Above 500 deg. C. the strength curve rapidly rises, reaching a maximum when the alloy is heated for 2 hr. at a temperature of 650 deg. C. By referring to the equilibrium diagram, Fig. 2, it will be observed that this is about the transition range from the alpha plus beta into the pure beta field. The drop in the strength curve above 650 deg. may be accounted for in the large grain growth which takes place at these high temperatures. This is brought out by comparing microphotographs Figs. 10 and 14.

The two curves shown in Fig. 3 representing the reduction of area and the per cent elongation will give a good idea of the variation in ductility of the metal under these treatments. They show that at the lower temperatures the ductility is somewhat increased by the relieving of the internal strains. The general tendency of the curves is downward, however, showing a decrease of ductility as the temperature of quenching increases.

From the results of these tests it is possible to pick out the best heat treatment for a given result. If maximum strength together with high ductility is required, the curves show us that heating for two hours at a temperature of 600 to 650 deg. C. will give the best results.

The effects of this treatment on the hardness of the metal is also of interest. In these tests the Brinell hardness increased from 124 to 144 as the temperature of quenching increased. The Brinell method is open to some criticism in the measurement of these soft alloys, as the metal will flow under the load. For this reason the time which the load is allowed to remain on the specimen is very important. The longer the time the lower the hardness, time being a factor which obviously should not affect the hardness.

Alloy AA When Slowly Cooled

A series of treatments subjecting alloy AA to very slow cooling after having been held at the various temperatures for 2 hr. were carried out, 50 deg. increments being taken as before in the range from 400 to 800 deg. C. The specimens were heated at the rate of 70 deg. C. per 5 minutes.

After holding the specimen at a constant temperature

for 2 hr. the current was entirely shut off and the closed furnace allowed to cool slowly. The rate of this cooling is given in Table IV, over 8 hr. being required for the furnace to cool from 800 deg. C. to room temperature. Check specimens were used in each case and a micro specimen prepared for each treatment. The results obtained from the physical tests of these heat-treated specimens are plotted in Fig. 4.

The tensile strength curve shows that slow cooling without mechanical work on the metal seems to greatly weaken it. This may be due to grain growth, which is free to take place under such conditions. The micrographs of this metal are shown in Figs. 11, 12, and 13.

TABLE IV. COOLING CURVE OF CLOSED TUBE FURNACE

Time, Hr.	Temp., Deg. F.	Time, Hr.	Temp., Deg. F.
0	1470	2	560
½	1010	3	390
1	820	4	280
1½	680	5	210

Even though the alloy is in the beta condition at high temperature (Fig. 14) large alpha crystals separate out during the slow cooling. The ductility curves show a marked similarity throughout the whole range. Comparing the strength curve, one might expect to find an increase of ductility as the annealing temperature increased. This is not the case, however, because it increases at first, then drops rather sharply and finally rises very noticeably at the end of the range; the maximum point at the higher temperature is, in fact, higher than at the beginning. It is interesting to note that the strength is lowered considerably below that obtained from the other treatments thus far carried out and that this treatment increases the elongation and the reduction of area to a very marked amount. Where strength is not of vital importance this treatment will produce an alloy which will resist shock in an excellent manner. Heating to 500 deg. C. and slowly cooling will relieve the strains due to drawing and will give a material of high ductility and good strength.

Comparison Between Quenching and Slow Cooling

It may be of interest here to compare the results obtained from these two radically different heat treatments. At a temperature of 650 deg. C. the strength differs by more than 20,000 lb. per sq.in. under these two treatments. Under quenching the general trend of the strength curve is to rise, while under annealing the trend is definitely downward. By means of the two charts one may obtain almost any strength desired within the range of the metal. The ductility curves are very irregular, but in general the ductility of the annealed material is higher than expected. Quenched material has low ductility at the high temperatures.

It may be concluded as a general deduction from these experiments that the quenching treatment produced a high strength-low ductility material and that the annealing treatments produced high ductility with relatively low strength.

Several of the specimens broke in the prick punch marks and in the threads. The material seemed very brittle and caused considerable trouble in this way, often breaking without warning and with a sharp report. Strangely enough this trouble seemed most evident in the slowly cooled specimens.

Sections of the treated specimens were carefully filed and polished before the hardness was taken. A dead load of 500 kg. was used with a ball of 10 mm. diameter. The load was permitted to remain on the specimen exactly 30 seconds, since it was soon discovered that the time factor was very important. The hardness of these alloys does not seem to be affected by heat treatment; the small variations noted are due to unavoidable errors.

Heat Treatment of Alloy A

Alloy A, containing 60.53 per cent copper, 38.67 per cent zinc, 0.75 per cent tin and no lead, was treated exactly the same as has been described for alloy AA.

Alloy A Quenched

Fig. 5 gives the results of the physical tests on the quenched specimens. The strength of the alloy is increased by this quenching treatment, especially at the higher temperatures. The initial strength of the bar as received, it should be remembered, is considerably below that of alloy AA. Note the rapid falling off in the strength when heated and quenched above 700 deg. C., this again being due to grain growth. Pure beta brass is not obtained with this material, high strength being obtained by fixing the structure in the alpha plus beta region.

Fig. 5 also gives ductility curves. These are of special interest because of the way the high ductility holds

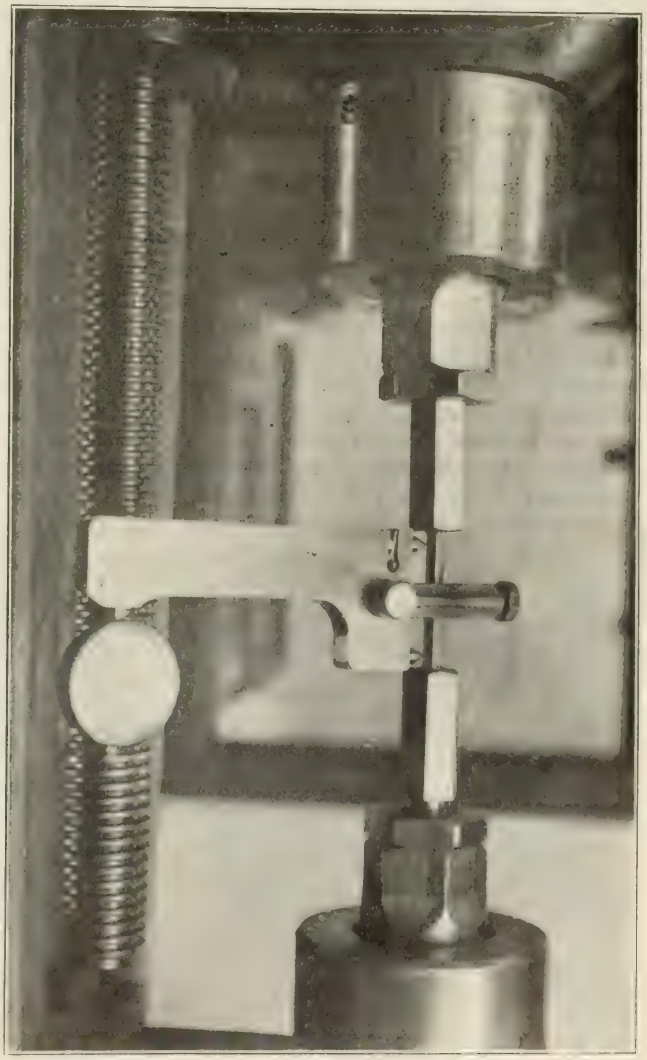

FIG. 7. TEST PIECE MOUNTED, WITH EXTENSOMETER ATTACHED

even at high quenching temperatures. Note that the reduction of area actually reaches 50 per cent and remains there up to a quenching temperature of 550 deg. C. The strength is correspondingly low in these ranges. The two ductility curves are strikingly parallel, and it is worthy of note that the ductility stays above that of the untreated alloy, which is shown in both cases by the horizontal line, until a quenching temperature of nearly 700 deg. C. has been reached. From these curves the best treatment to produce and desired combination of strength and ductility may be procured.

TABLE V. HARDNESS OF ALLOY A AFTER QUENCHING

Quenching Temperature	Brinell Hardness	Quenching Temperature	Brinell Hardnes
400	94	650	96
450	94	700	102
500	92	750	114
550	89	800	119
600	92		

The hardness number under the Brinell test showed a general tendency to increase as the temperature of quenching increased. The scleroscope hardness on the other hand showed no appreciable change. These data are given in Table V.

Alloy A Slowly Cooled

The same slow cooling treatment was applied to this alloy as that described above for alloy AA, the closed electric tube furnace was used as before and the rate of cooling was exactly the same. The curves given in Fig. 6 show the tests graphically. Decrease in strength due to this annealing treatment is very evident. The whole curve is below the line for untreated rod. There is a range between 600 and 700 deg. C. as before where the strength rises, but the total variation in strength due to annealing is not very great.

The ductility curves are very striking. Note the enormous increase in both elongation and reduction in area. The former is greater than the latter. These curves are quite parallel and show that the ductility holds up even at high temperatures. It will at once be apparent that fairly high strength and very high ductility can be obtained in one material and one rod. Take such a treatment for example as heating for 2 hr. at a temperature of 650 deg. C. and then slowly cooling. This treatment has not affected the strength, but the ductility has been increased from 21 per cent elongation to about 47 per cent, representing a 100 per cent increase. If a slightly lower strength is just as satisfactory, this high temperature need not be employed, since the curves show about the same ductility for an annealing temperature of 450 deg C.

Microscopic study showed that the original structure shown in Fig. 9 was somewhat recrystallized after an annealing at 500 deg. C., the crystals losing their parallel orientation and disintegrating somewhat. Annealing at 650 increased this tendency, the alpha crystals being materially spheroidized. Fig. 15 shows the structure

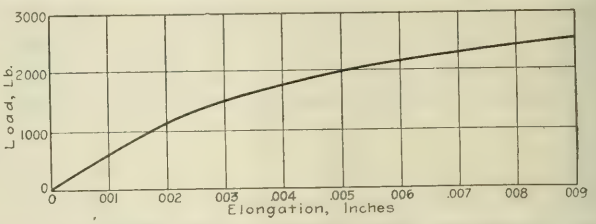

FIG. 8. STRESS-STRAIN CURVE FOR SPECIMEN A29

on annealing at 800 deg. C. Evidently the whole metal reverted to large crystals of solid solution, which decomposed to a certain extent on slow cooling.

Comparison Between Quenching and Slow Cooling

When comparing annealed with quenched specimens the differing values of the untreated samples must be considered. The specimens used for the quenching tests were of higher strength and lower ductility than those used for the slowly cooled treatments. For this reason the difference shown by the two curves must be properly discounted. It will be recalled that all these specimens were cut from the same run of metal and not far removed from each other as the metal came through the die.

Reduction of area falls off above 600 deg. C. when the alloy is quenched, but this property is maintained at a high value by slow cooling. Even at 800 deg. C. the ductility had not appreciably diminished. It is also interesting to note that the ductility is nearly as high with the quenched specimens up to a temperature of 550 deg. C. as it is with the annealed alloy. This is significant, as it shows that no appreciable change has taken place in the structure due to the heating up to this point. This is probably due to the change from the alpha plus gamma, which is present at ordinary temperatures, to the alpha plus beta, stable at that tempera-

ture, taking place at low velocity. If the alloy were heated for an extended time at say 500 deg. C. it is probable that the quenching would produce a smaller ductility, as more of the structure would be transformed.

Stress-Strain Curves

Two specimens marked A20 and A29 were selected for extensometer tests. A sensitive instrument shown in Fig. 7 was used, with which 0.0002 in. could be read. Loading was carefully applied by hand. For the range considered the reduction of area was so small that the stress was considered as being applied on the original area. The strain, or elongation in inches per inch, is plotted on Fig. 8 for specimen A29.

As before, the elastic limit is well marked at about 1,100 lb. load. When transferred into standard units we have the true elastic limit, at 12,000 lb. per sq.in. (Length of specimen 2 in., initial area 0.0913 sq.in.)

When these values are substituted in the formula we have

$$E = \frac{12{,}000}{0.00095} = 12{,}630{,}000$$

Specimen A20 gave an elastic limit of 11,000 lb. per sq.in. and a modulus of 16,900,000.

Evidently considerable variation occurred in the modulus of elasticity as determined from the tests of these two specimens. This variation was due almost entirely to the greater strain occurring in A29, the elastic limit occurred at about the same point in both specimens. It would appear from these limited tests that 12,000 lb. per sq.in. is about right for the elastic limit, a very low value, but such is to be expected in copper-zinc alloys. The elastic limit appears to be about 20 per cent of the ultimate tensile strength. No yield point, or so-called commercial elastic limit, could be detected in any of the specimens tested. If there were a yield point it was too small to affect the beam.

Microstudy

In order to supplement the data and information obtained from the physical study and tests outlined above for these various heat treatments a number of microphotographs were taken. In each case an attempt was made to study the structure at those points where the physical properties, as shown by the accompanying curves, abruptly changed.

Polishing

Fine floated rouge on broadcloth would not give the desired results, and a surface free from fine scratches was finally obtained by using very finely powdered alumina with water on the polishing wheel. Even with this abrasive a large amount of work was necessary to produce a satisfactory surface for etching.

Etching

Numerous acid and basic reagents may be used depending upon the structure which it is desired to bring out and the constituent which it is desired to have attacked. The etching reagent used on these specimens was chromic acid (H_2CrO_4) crystals dissolved in water. This attacks beta constituent more rapidly than alpha; the latter appears white in the photographs. The acid solution was rubbed on the polished surface of the specimen with the finger to insure good contact and allowed to remain for about 30 seconds. In case this treatment did not bring out the structure the above operation was repeated until a sharp outline of the structure appeared under the microscope.

Production of Gold and Silver in the United States in 1919

The Bureau of the Mint and the Geological Survey have issued the following preliminary estimate of the production of gold and silver in the United States during the calendar year 1919:

State or Territory	Gold		Silver	
	Fine Oz.	Value	Fine Oz.	Value*
Alaska	437,131	$9,036,300	1,072,137	$1,201,705
Arizona	202,038	4,176,500	4,296,769	4,816,033
California	840,758	17,380,000	1,204,004	1,349,508
Colorado	470,998	9,736,400	6,044,911	6,775,438
Georgia	48	1,000	10	11
Idaho	34,365	710,400	6,042,01[illegible]	6,772,194

* Value at the average New York price of fine silver, $1.12085 per oz.

These figures, compared with those for 1918, show a reduction in the output of gold of $10,157,900 and in that of silver of 12,524,943 oz.; compared with those for 1917 they show a reduction of $25,261,900, and in silver of 16,455,166 oz.

Lessons for Chemical Engineers in Other Industries*

By A. E. Marshall

WAR-TIME demand for the products of the chemical industry has of necessity resulted in improvements in chemical engineering practice during the last three years. Inability of the factories in existence at the outbreak of the war to cope with war requirements was responsible for the erection, in this country and in England, of plants designed to produce large tonnage outputs of specific finished materials. As the desired capacity was known in advance and as the product was definite, the designers of these plants had opportunities in arrangement of units which are lacking to a certain extent in the design of factories which have an indefinite future capacity and which will have to be extended later to take care of new products and byproducts.

Yet an inspection of a number of the war-time American factories, and six weeks spent in the English factories during the early summer of this year, have resulted in a conclusion that full advantage was not taken of routing of operations and of labor-saving devices which in other industries had reached advanced states of development. The imperative need for production and the necessity of adapting equipment available during the building of the plants have to be taken into account, and a full knowledge of the difficulties in securing prompt supplies of adequate machinery would doubtless modify in some measure conclusions based only on a study of the completed plants. Even with such allowance, a survey of the latest developments of chemical engineering leaves a sufficient reason for the suggestion that the chemical engineer should broaden his lines of study from the limited one of the purely chemical field to the wider viewpoint of engineering work and operation in other industries which present problems analagous to the manufacture of chemicals. A chemical engineer, or a chemical plant executive, is prone to believe that his manufacturing problems are peculiar not only to the chemical industry but even to his specific branch of the industry, whereas other industries have had similar problems and have reached solutions.

Chemical Plants Built Wrong

In the past, the average chemical plant has started out as a producer of one or of several standard chemical products, and with the development of the business, new but usually inter-related products have been added to the factory output. Invariably the original design was a complete unit, so that even an increase in the output of the original products necessitated the addition of separate complete units without the possibility of effecting economies through the use of labor-saving devices applicable only to tonnage movements. When extensions through the multiplication of products became necessary, the situation was much worse, as the new additions had to be located externally to the original plant unit, and the conveyance of materials produced in the original plant to the new units in which they were to be utilized was necessarily reduced to primitive forms of transportation. There are few industries today other than chemical manufacture which present the anachronism of manual handling the semi-finished product of one operation to its final point of utilization.

A generalization of this nature must of course be qualified by exceptions in the case of plants designed to produce large tonnages of the low-priced chemical staples, or as they are more generally termed, "heavy chemicals." Such factories invariably have labor-saving tonnage movement devices, although they are not always in the forward state of development of the means used in other industries. This difference in chemical factories is clearly evident in comparing the facilities for moving raw and finished materials in, say, a large-tonnage ammonia-soda plant, and a plant producing six or eight products by stages. The soda plant will move its materials progressively with mechanisms which require the smallest amount of human labor, whereas the average several-product factory makes each separate movement discontinuous. Between the various inter-related units of a several-product chemical factory there is frequently a bottle-neck of transportation of materials.

Examples in the South

The South furnishes through its fertilizer industry excellent examples of discontinuous work. A fertilizer plant can be as well ordered in its progressive stages of manufacture as an automobile plant, but the majority of the fertilizer factories move their entire material in process at least once and sometimes twice by hand labor in buggies. Labor in the South was once cheap. These conditions have changed with apparently no chance of return, and so the fertilizer manufacturer, and the chemical engineer specializing in fertilizer plant design, will be forced to build new plants in which economies in labor are possible. This brings up the point of original design of chemical plants and the necessity of designing with an eye to the future.

Suggestions From Other Fields

Some chemical plants built within the last five years will find it difficult to make extensions which permit of a lowered cost of production or even a cost equal to the original plant, for reasons such as lack of strength in the building structure preventing the employment of monorail cranes or similar mechanism to convey supplies of raw materials from the original storage bins or piles to the new extensions. Time can more profitably be spent in designing the present to suit the future than in trying to add in the future to a completed unit which has no outlets for expansion.

The statement made in the early part of this paper that other industries can furnish useful ideas to the designer and the operator of chemical plants is intended as a suggestion. To cover in detail the comparisons which present themselves would require several papers, so that an attempt will be made to simply draw attention to some developments in other industries which are just finding their way into the chemical field or which are still awaiting proper recognition.

As a preliminary, there are some useful guide posts on the road along which the industry has passed. Take the Chemical Catalog, which is issued under the auspices of this Institute, and compare the mechanical and labor-saving devices shown in the first volume (1916) with the much greater variety in the present (1919) volume. The manufacturers are not listing plant equipment in 1919 that was not in existence in 1916, but rather they are listing equipment which in 1916 was used only in other industries. Compare also the advertising pages of the chemical journals, say, from 1912 to the present time, and note the introduction into chemical

*Read at the Savannah meeting of the American Institute of Chemical Engineers, December, 1919.

advertising, of filters which had found extensive use in the metallurgical field, of grinding machinery primarily developed for metallurgical plants and cement mills, belt conveyors, monorail cranes, grab buckets and other mechanical devices for handling materials which were introduced into chemical manufacturing processes after they had become standardized in other industries. And today other industries have in use types of equipment which would solve many of the problems we consider solely as chemical engineering problems.

Moving Materials

First, there is the matter of moving materials through the cycle of the plant operation. The movement, at the lowest possible cost, of large tonnages of raw and finished materials has assumed great importance in industries where there is close price competition. The progress of chemical manufacture with the consequent increase in size of chemical plants will make this feature of plant design of vital interest to the owners of these plants. Waterfront factories bringing in their raw material by steamer will be forced to adopt unloading methods equivalent to those used in the iron and steel industry. Factories in the interior will have to be arranged so that railroad cars can be placed directly at the discharging or loading points so that double handling of materials is avoided. The linkage of materials, moving from one part of the plant to another, and referred to in the earlier part of this paper, will have to be changed from manual to mechanical means, and the plant units so arranged that the intervals to be bridged in the movement occupy the shortest possible distance while still permitting the future growth of the units.

All of these improvements in handling have become part of the routine design of other industries, and the chemical engineer, by extending his observation outside of the chemical field, can usually find an operation with characteristics similar to the project he is interested in, which has developed handling facilities adaptable by him.

Central Station Power Plant

In the case of the chemical engineer concerned in the layout of a furnacing operation, a study of a modern central station power plant will suggest improvements over existing chemical practice. There are many chemical plants which use as much coal under furnaces each day as a large power plant does under its boilers. The power plant is in the business of utilizing coal for profit, so it has, in the movement of coal, displaced manual labor by mechanical methods. The power plant unloads its coal into storage with grab buckets operated from gantry or overhead cranes, and has developed other forms of mechanical equipment to convey the coal from storage to the boiler room and to the individual mechanical stokers. The ash from the boilers is gathered either by drag conveyors, pressure or suction devices and is delivered to hoppers which discharge direct into cars or ash scows. The arrangement of the average chemical plant carrying on furnacing operations effectually prevents the use of a complete scheme of mechanically handling coal and ashes, as the furnaces have grown, Topsy-like, in various parts of the factory, and even the coal storage must usually be placed remote from the furnaces.

The control of combustion, which is essentially a chemical problem, has progressed to a greater extent in power plants than in chemical factories, and it is the unusual chemical factory which has its furnaces equipped with CO_2 recorders, pyrometers, and draft-gages.

Further suggestions along these same lines are afforded by the study of flow sheets of metallurgical works. The flow sheet of a modern smelter with its allied leaching and flotation plants represents a development in low cost movement far ahead of the average large chemical plant, although the equipment used in the smelter is in many instances equally serviceable in chemical factories. Leaching by counter-current decantation in its present efficient state is a development due to metallurgical engineers who were faced with the problem of economically treating low-grade ores. The same apparatus will serve the chemical manufacturer for the production of solutions or an insoluble precipitate through the interaction of a solid and a solvent or solution. Various types of classifiers have made closed circuit grinding a possibility, and the chemical manufacturer can adopt from the metallurgist a method of operation which gives a continuous finely ground product without a distinct intermediate separation.

Brief mention has already been made of filters used in metallurgical work and of their adoption in chemical processes. The continuous removal of a solid product from a waste liquid or the continuous separation of a solution from a waste solid in suspension means a great reduction in cost as compared to the use of intermittent plate and frame presses.

Use of Gas Washers

The various processes of illuminating gas manufacture afford useful study, and some interesting developments should result from the adoption by the chemical industry of gas washers of the Feld type. Feld washers have provided the gas engineer with a compact mechanism which gives an intimate contact between the gas and an absorbing or scrubbing liquid, while the arrangement of the washer permits the liquid to reach a high concentration in solid particles without danger of stoppage. A cast iron washer of this type would, as an example, remove chlorine, using caustic soda solution as the liquid, from the exit of a chlorinating operation, and going for the moment outside the strictly chemical field, it might serve in an absorption method of recovering gasoline from natural gas, in place of the present expensive compressor plants. Made of acid-proof materials, and somewhat modified in arrangement, this same type of washer might be used to replace one of the unsatisfactory details in a sulphuric acid chamber plant —the Gay-Lussac tower.

Adaptability of Grain Unloaders

As an illustration of the satisfactory use of mechanisms developed in other industries, an instance at the factory with which the writer is connected may be cited. One portion of the plant operation depends on the continuous supply of large tonnages of raw material. Prior to 1918 this raw material had always been delivered at the plant in steamers—and a complete scheme of mechanical unloading had been installed and had given excellent results. The shipping strike and the shortage of steamers in 1918 made it necessary to change over from steamer to box car conveyance, and as the raw material was used at the rate of 600 tons a day it meant either excessive hand labor in unloading the cars or the adoption of some mechanical unloading device. A review of practice in the chemical industry did not afford any suggestions, neither did the usual engineering catalogues or trade publications refer to a machine which would solve the problem. Consideration of materials that were

moved in tonnages in box cars led to an investigation of the grain trade, and it was found that grain elevators had been using a mechanical box car unloading device for at least ten years and that this device could be adopted without change to our conditions.

Grain unloaders were installed, and the congestion of plant facilities which would have occurred under hand unloading conditions were avoided, and, most important of all, the cost of putting the material into the plant was kept down to a reasonable figure.

Conclusion

The examples which have been selected do not exhaust the possibilities of comparison, but they will serve the writer's purpose if they are accepted as evidence in support of the conclusions that the chemical engineer can study, to his advantage, engineering progress in other lines of industry.

Crucible Graphite

GRAPHITE for making crucibles should be of the crystalline variety and should have a high degree of purity, according to *Mineral Resources*, 1918, Part II. Most makers of crucibles prefer to use Ceylon graphite either alone or mixed with varying proportions of American flake, usually not exceeding 25 per cent of the mixture. The reason for this preference is in part because the more nearly cubical fragments of Ceylon graphite have a much smaller surface area in proportion to their volume than the thin flakes of domestic graphite and hence require proportionately less clay as a binder. Ceylon graphite is also said to be more nearly free from undesirable impurities, such as mica and pyrite. It is possible, however, to use domestic flake graphite alone with good success in crucible manufacture.

Specifications as to graphite for use in crucibles vary widely. Dub[1] suggests the following specifications for American graphite for use in crucibles:

"It is recommended that the graphitic carbon contents of No. 1 flake be not less than 85 per cent. By graphitic carbon is tentatively meant the carbon remaining after the dried sample has been burned for 3 min. at 800 deg. C."

The following tentative specifications as to screen analysis for No. 1 flake are recommended:

	Per Cent
Over 35 standard mesh	3
Over 65 standard mesh	50
Over 100 standard mesh	100

The following analyses show the present practice:

[1]Dub, George D., "Preparation of Crucible Graphite." Bureau of Mines War Min. Inv. Ser. 3, pp. 20-21, December, 1918.

[2]Spence, H. S., "Canadian Graphite Industry," Mines Branch Summary Report for 1917, p. 50, 1918.

It has been found in practice that although flake carrying 85 per cent of graphitic carbon can be readily produced, the cost of a product containing 90 per cent of graphitic carbon is very greatly increased. This is owing to the fact that small quantities of quartz, mica and other impurities are interbedded in the graphite flakes themselves, and the flake must be broken to remove them. Seemingly pure graphite flakes were on analysis found to contain only slightly more than 90 per cent of carbon.[3] A sample of Ceylon graphite prepared for crucible use contained 85.06 per cent of graphitic carbon.[2] In purity, therefore, the American graphite compares favorably with that from Ceylon. The question of the relative value of American and Ceylon graphite for use in crucibles is now being investigated by the Bureau of Mines.

Use of Graphite for Crucibles Decreasing

The graphite consumed yearly for crucibles in this country for 1916 and 1917 amounted to about 24,000 tons. It is probable that more than 90 per cent of the graphite used was of foreign origin. During 1918 the graphite consumed for crucibles was probably not more than 20,000 tons. This decrease was due in part to the increased use of electric steel furnaces and open-flame brass furnaces, in part to the export on war orders of raw materials rather than manufactured finished products, and in part also to the fact that a better quality of crucible was made, thus reducing the quantity of crucible graphite used. The normal peace-time requirements of crucible graphite, as measured by the apparent consumption for the years 1911 to 1913, probably do not exceed 13,000 tons a year. It is probable that the further demand for crucibles will diminish rather than increase.

Rapid Increase in the Manufacture of Electric Furnace Steel

The following table shows a rapid increase in the manufacture of electric furnace steel, while the production of crucible steel has remained stationary.

STEEL INGOTS AND CASTINGS PRODUCED IN THE UNITED STATES, 1908–1917, BY PROCESSES, IN GROSS TONS[4]

	Crucible	Electric		Crucible	Electric
1908	63,631	...	1913	121,226	30,180
1909	107,355	13,762	1914	89,869	24,009
1910	122,303	52,141	1915	113,782	69,412
1911	97,653	29,105	1916	129,692	168,918
1912	121,517	18,309	1917	126,716	304,543

It is believed that with the return to normal conditions this difference will be further accentuated. Recent developments in the electric furnace as applied to non-ferrous alloys also give promise of a decrease in the use of crucibles. It is even stated that the time is ripe for the practical elimination of the crucible from the brass industry.[5] A rocking electric furnace designed in the Bureau of Mines showed costs of operation about one-half that of the coke-fired crucible furnaces used in the same plant.[6] It was found that the cost to melt cupro-nickel, the most refractory alloy handled at the mint, in an electric furnace was less than half that in the gas-fired crucible furnace.[7]

The Technical Engineer's Judgment of the Oxy-Acetylene Process

By Alfred S. Kinsey*

THE commercial success of a mechanical process or device often may depend on two factors: Its utility as determined by the manufacturer, and its efficiency as judged by the technical engineer. No one knows better than does the owner of the metal-working plant or the superintendent of the repair shop how great the need has been for quicker and more thorough methods of manufacture and ways of making repairs, and few have looked forward with greater interest than has the mechanical engineer to the coming of safer and more efficient mechanical devices and processes. One has been the stimulus of the inventor, the other the surety of the manufacturing world.

The technical engineer's position in this progressive age requires no evalution, his critical scientific attitude no defense. His is the problem of casting beyond the superficiality to the durability of things, from the flimsy to the substantial. Unquestionably this has produced in the engineer a conservatism, a habit of close inquiry, which makes for safety and success. The manufacturing world therefore still seeks the judgment of such a mind, and the technical engineer's indorsement is often final. It may be of interest therefore to learn what he thinks of such a modern process as that of oxy-acetylene welding.

Forge Welding

Up to the advent of autogenous welding the engineer had only his experience with the forge weld upon which to base his calculations and judgment. In a way this proved somewhat unfortunate for the new method of welding, as the forge weld has nearly lost its value as a dependable means of joining metals. Imagine two pieces of steel being brought to a soft plastic condition in a forge fire charged with sulphur from the fuel, an excess of oxygen from the indifferently operated bellows or fan blower, the cinders and refuse of the fuel, and one can readily realize the cause of weak forge welds. Such welds never were reckoned to have a tensile efficiency of more than about 50 per cent, and many observations of welds which had failed showed crystallization and even entrapped cinders. Navy yards and many other large shops had practically abandoned the forge weld, preferring the expensive substitute of machining a job out of the solid when it was possible to do so. Serious failures of forge welds were too common. The author recalls many of these, and particularly one regarding which he assisted in a suit for damages where a hoisting hook on a city pier had parted at the weld, causing the death of the father of a family of small children. There was a demand for a safer and more efficient way to weld steel and wrought iron.

Then, too, in those earlier days the only metals which could be welded were wrought iron and steel. There was no way to weld cast iron and the non-ferrous metals like copper, brass, aluminum. The mechanical engineer, of all men, realized these limitations. He knew that the time was ripe for a new method of welding metals.

Then came autogenous welding and cutting by the oxy-hydrogen process, soon to be superseded by oxy-acetylene, thanks to the electric furnace's efficient method of producing calcium carbide and making acetylene a commercial possibility. From that time—practically only about fifteen years ago—metal workers, manufacturers, engineers, nearly the whole industrial world, have eagerly watched the progress of the oxy-acetylene process. The mechanical engineer recognized at once that there were certain fundamental principles involved in oxy-acetylene welding which were new to shop practice, such as:

Comparative Results of Forge and Oxy-Acetylene Welding

The autogenous welding was accomplished by fusion instead of plasticity. The old method required that the metal be heated merely to a soft pasty condition and then hammered or pressed together, while the new way was to melt the metal and flow the two ends into one mass. By the former method there could not be a thorough mingling of the grains of the metal, because it was only plastic, and besides there was every opportunity for such a weld to receive gas and fuel impurities from the forge fire. By the new process there could be nearly perfect rearrangement of the grains due to the liquid condition of the metal. The mechanical engineer recognized at once, however, that while the fusion of castings for welding would be consistent with the method of their formation, that is, that both the original metal and the weld itself would be in the cast condition, this would not be true in the case of the welding of rolled or forged wrought iron or steel. There the two pieces of rolled or forged metal would be joined by a cast weld, the former being fine grained and strong, the latter of coarse grains and reduced tensile strength. This was not a new situation to the engineer. The benefits derived from hammer-refining the grains of steel are well known. An ordinary machinist hammer therefore proved to be the cure of this trouble, and it may be of interest to relate that in some experiments performed during the past year by the author for the Air Reduction Co. of New York at the shops of the Baltimore & Ohio Railroad at Martinsburg, W. Va., and at Brunswick, Md., some worn railroad frogs which were built up by the oxy-acetylene process and allowed to cool directly from the liquid in the solid condition lasted only a few weeks in service, but when a progressive method of building up and hammering was resorted to some of the frogs lasted over 9 months in continuous severe service.

Broader Adaptability of the Oxy-Acetylene Method

As fusion is the chief requisite of a good weld, the new process might be used to join other metals than wrought iron and steel. This opened up wonderful possibilities, new indeed to welders, for cast iron and the non-ferrous metals had not yet been welded. Would it be possible for the new welders to learn the marked differences of characteristics of steel, cast iron, copper, brass, aluminum? We have but to call to mind the work being done in the welding of iron castings alone to get an answer and to form an idea of the possibilities and value of the oxy-acetylene process for the welding of cast iron. The author recently had to do with the oxy-acetylene welding of three broken cast iron cylinders of freight locomotives, which cost $515

*Professor of Shop Practice, Stevens Institute of Technology, and Advisory Engineer, Air Reduction Co., 120 Broadway, N. Y.

to weld and put in good working order, but would have cost $3600 to replace by new cylinders if oxy-acetylene welding had not been available, leaving out of consideration the long delay in getting the locomotives back in service by the old method of making repairs as compared with the few days' lay-up for welding.

The gases used in an oxy-acetylene torch operated by inexperienced welders might easily be made to lower the value of the weld. Many of the first oxy-acetylene welds were badly crystallized. The engineer knew this and waited for developments. The first designs of torches were much to blame for this condition, but the inexperience of the welder was more so. It is not unusual now to find oxy-acetylene welds so homogeneous as to make it practically impossible to see any difference between the original material and its weld.

The unusual problems of expansion and contraction must be reckoned with in the job welded by oxy-acetylene. No one would attempt to dispute this. The cautiousness of the engineer in this regard may well be understood. It has required an experimental experience to master these difficulties, but they do not stand in our way now.

The heating of the oxy-acetylene weld being accomplished by the powerful quick-acting flame instead of a slow forge fire, it can readily be seen that a trained eye would be required to bring about good results from the working of the metal in the molten condition. What would happen if the metal were overheated? What if the original metal were not thoroughly melted when the molten rod was dropped upon it? A man must know more than a blacksmith about hot metals to be an oxy-acetylene welder. Could such men be gotten and could their skill be relied upon? We know the encouraging answer to these questions now, but they recall to some at least the time of not so long ago when the mechanical engineer struggled with his welders to teach them the difference between molten metal and burnt metal. We venture to say that it will be much easier to make good oxy-acetylene welders from now on than it has been heretofore.

Need of Training Oxy-Acetylene Welders

The author's experience of the war-time period illustrates the need of training for the special work of oxy-acetylene welding. There was a great demand for the use of the oxy-acetylene welding and cutting of metals. Trained welders were scarce and many men were being pressed into the work without proper knowledge of the way it should be performed. At the request of those in charge of these men it became our privilege to form a night school for oxy-acetylene welders at the Twenty-third Street Y. M. C. A., New York. The course consisted of lectures on the metallurgy and general principles of the work followed by the actual use of the welding and cutting torches on special jobs in the shop. We took in men who were working on war orders in the shipyards and other large shops, and also any other men who would learn to be welders and take positions in the shops doing war work. Over 200 men were trained the first year, about 75 per cent of whom proved to be successful welders, so far as we have been able to follow them up. It was easy to see why these men were failing in their daily labors with the torch, and their rapid advancement after a few evenings of instruction clearly proved the importance of a special training in the subject. As a more marked illustration of the value of such a training, however, we may mention an experiment in this same evening school of a special class selected from the non-essential industries. The men had been earning a livelihood as furniture salesman, laundryman, hat dyer, printer, bookkeeper, waiter, plasterer, signalman, art student, saloonkeeper, etc. Seventeen out of the twenty in the class became good welders, and went to work in shipyard and shop with a zeal that was surprisingly new to them.

Teaching the Uses of Oxy-Acetylene Processes

It is timely to outline the attitude of the technical engineer toward the teaching of the oxy-acetylene processes in the engineering colleges. Some of these institutions were not slow to grasp the importance of the subject. The Stevens Institute of Technology was probably the first college to take up the work. The author has lectured for about ten years on the subject as head of the department of shop practice in that institution and some time ago we added a course of jobs to be welded by the oxy-acetylene torch which every student at Stevens has been required to take. We have heard of other engineering colleges which have introduced such a course, and we understand that Harvard's new Engineering School is about to include oxy-acetylene welding in the instruction of its shop department.

In college and abroad in the world of engineering construction and repairs the technical engineer has been giving careful thought to the possibilities and advantages of oxy-acetylene welding. He has encouraged its trial in shop, foundry and manufacturing plant. He has studied its evolution from the rough joint of doubtful value to the homogeneous weld of nearly 100 per cent efficiency. If he has been conservative in his judgment it was because he knew better than others of the undeveloped parts of the new field being entered by the welder; if he has appeared to be slow to accept the process for the most important high pressure and high tension work it is because he has waited to prove that the new welder could measure up to his increased responsibility. One thing he will not do, he will not forget the inherent crudeness of the work, nor the varying personal error of the best workmen, and expect impractical refinements. A small fraction of sulphuretted hydrogen and phosphoretted hydrogen in the acetylene or a little difference in the purity of oxygen will not disturb his acquired confidence in the possibilities of a good weld by the new process. He has learned to appreciate the difference between a 50 per cent plastic weld and a 90 per cent fusion weld.

Generalization

The author has discussed oxy-acetylene welding with many of the leading technical engineers of the country, men who are in responsible charge of immense engineering plants. Five years ago almost all of these men would have advised a delayed acceptance and further study of the advantages of the process. Today they do not hesitate. Their minds are made up. From study and experience they speak, and because of the nature of the heat supply which can easily be made a non-oxidizing reducing flame, because of the effect of the process on the physical efficiency of the actual weld, because of the portability of the welding apparatus, and because of the economy of the process, their judgment is that the oxy-acetylene process of welding metals is an engineering success and a fine commercial asset.

Fatigue Research in Tinplate Manufacture*

THE Industrial Fatigue Research Board has issued an interesting report on "The Influence of Hours of Work and of Ventilation on Output in Tinplate Manufacture," by Dr. H. M. Vernon, an investigator to the Board. According to this the hours actually worked up to the beginning of 1919 by the tinplate workers very seldom exceeded 54 per week, and were usually considerably fewer than this. The millmen usually worked five or six 8-hr. shifts per week; but their work is so heavy that a reduction to 6-hr. shifts, making 30 to 36 hours per week, has been proposed.

Duties of Millmen

The millmen work in groups of four, consisting of a rollerman, a doubler, a furnaceman and a behinder. Each rolling mill consists of two pairs of rolls and two, or occasionally three, furnaces. The doubler charges one of the furnaces with a definite number of steel bars, usually 30 to 46, which take about an hour to reach the required temperature. They are usually about 9 in. wide, 20 in. long, and $\frac{3}{8}$ to $\frac{7}{8}$ in. thick, and weigh 20 to 40 lb. The doubler pulls out the bars, two at a time, from the furnace, pushes them along the floor to one pair of rolls, and rests them on a small tank, about 2 ft. in height. The rollerman takes up each bar separately and passes it between the rolls, while the behinder, on the other side, grasps and raises it to the top of the upper roll, and thus it is carried back to the rollerman. Each bar is passed through the rolls four or five times, and gets rolled out to a sheet. The rollerman takes hold of the two sheets together and flings them across the floor to the doubler, who returns them to the furnace. To do this, he has to lift a weight of 40 to 80 lb. a height of over 3 ft.

The rolling of the 15 to 23 pairs of bars takes 10 or 12 minutes, and the squad of workers usually pause for about two minutes at the end of it. Then the furnaceman (who has been resting during the first stage of the rolling, or stoking his furnaces) withdraws the rolled bars from the furnace, one by one as they are wanted, and flings them across the floor to the rollerman. The rollerman passes them twice through the other pair of rolls, which are heated to a blue heat by constant contact with the red-hot sheets of metal. He flings each rolled sheet to the doubler, who doubles it over, presses on it with his foot, and raises it to a table about 2½ ft. in height. Here he places the folded portion under the squeezer, which flattens the two layers of the sheet together. He flings the sheet on the floor to the furnacer, who returns it to the furnace.

In the third stage of the rolling the twofold sheet is again passed twice through the hot rolls, and the doubler doubles it again, and with shears trims off the edges which have come together. In the fourth stage, the fourfold sheet is rolled, doubled and trimmed as before, while in the fifth and final stage the eightfold sheets are rolled out to the required length. This usually requires two passes through the rolls, but if after measurement the sheet is found to be too short, it is allowed to cool a little and is rolled again.

Finally, the behinder (who has been constantly returning the rolled sheets to the rollerman) pulls it on to the floor, and, in a single complex movement, swings it and his whole body round back to front, and bounces and lifts the sheets from the floor level on to a stand or a trolley. The trolley is about a foot above floor level, but the pile of sheets accumulate on it to a height of one or two feet, so it means a considerable effort to land the long thin sheet on the top.

The whole cycle of five stages was found to take about 96 minutes when 46 bars of 29 lb. each were rolled, and 78 minutes when 36 bars of 30 lb. each were rolled. There is never any break in the rolling process of more than a very few minutes right through the working week, i.e., from 6 a.m. on Monday till 2 p.m. (or 12 noon) on Saturday. The workmen seldom pause more than four minutes between any of the stages, and there is no delay when the shifts change, as the doubler of one shift puts in the furnace the bars required by the succeeding shift, and the fresh men are all ready and waiting to take their turn.

The temperature of the air near the millmen was found to be sometimes as high as 110 deg. F., but this figure gives an inadequate idea of the heat experienced. The red-hot sheets of metal manipulated by the men average about 4 sq.ft. in area, and at some stages the large sizes may attain 10 sq.ft. or more, so the radiant heat from them must be considerable. In addition, the furnacer, and at times the doubler, experience the radiant heat from the partly open furnace, while the rollerman and the behinder stand close to the heated rolls. All four men are constantly raising and lowering metal sheets and bars weighing 20 to 80 lb.; hence the physical effort of millmen's work is very great. The men stream with perspiration within a few minutes of starting work, and they drink many pints of home-brewed ginger beer, milk, cider and water during their shift in order to quench their thirst.

Influence of Hours of Work Upon Output

For inquiry into the influence of the hours of work upon output recourse was had: (1) to records, available in five factories, A, B, C, D, E, for periods dating back in one case to 1911, giving length of shifts worked and output obtained; (2) to a certain number of stop-watch measurements obtained in factories D, F, G of the times taken by millmen on 6- and 8-hr. shifts to work through the various operations, and the rest-pauses taken by these millmen. The influence of hours of work upon output lends itself to investigation in the case of millmen owing to the clear cut reductions of working hours to which their work is sometimes subjected. If some of the mills break down, or if there is a shortage of material, it is common custom to convert the three 8-hr. shifts into four 6-hr. shifts, or even into six 4-hr. shifts, in order that as many of the men as possible may be provided with work.

The author recapitulates his evidence thus: The very reliable data from the records at factory A showed the hourly output during 4-hr. shifts to be 11.5 per cent greater than that obtaining during 8-hr. shifts. Turning to 6-hr. shifts, the less reliable observations from factory C showed the output to be 8.5 per cent greater for the shorter hours; those at

*Abstracts from the *Iron and Coal Trades Review*, Sept. 12, 1919, p. 336.

factory D showed it to be 10.6 per cent greater (for a 19-week period); and those at factory E 4.7 per cent greater. Hence we may conclude with considerable probability that when 6-hr. shifts are worked the hourly output is about 10 per cent greater than when 8-hr. shifts are worked. However, this increment, small as it is, does not mean a corresponding increase of total output. The men stop at 12 on Saturday when they work 6-hr. shifts, or put in 126 hours per week, whereas they stop at 2 p. m. when they work 8-hr. shifts, or put in 128 hours per week. Hence the total output of the factory would be increased by only 8.3 per cent when 6-hr. shifts were substituted for 8-hr. shifts; i.e., a smaller improvement might presumably be brought about than by the installation of thoroughly efficient ventilation. Supposing it were possible to work an extra 6-hr. shift (i.e., till 6 p.m. on Saturday), the total output would be increased by 13.4 per cent, but the author has heard of no suggestion of this kind.

Seasonal Variation in Output

The fatiguing character of millmen's work is shown by the fact that their output varies with the atmospheric temperature, and is distinctly smaller in the summer than in the winter. The author was able to obtain data showing the weekly output per mill at the five factories A to E for a number of consecutive years which proved that there is a distinct seasonal variation in the output of the men. Their hourly output decreases as the weather grows warmer, and the degree of variation is dependent mainly on the ventilation. In a factory where a good ventilation was effected by means of large vertical fans or paddles, the mean output in the summer months (May to September) was only 2.9 per cent less than in the winter months (December to March). In two other factories where a moderately efficient ventilation was effected by cold-air douches, the summer output was 5.2 per cent less than that of the winter, while in two other factories, which had no artificial ventilation at all, it was 6.8 and 9.2 per cent less. The real effect of temperature on output is considerably greater than is indicated by these figures, for it was found that in the two unventilated factories the average output was, respectively, 11 and 18 per cent less in the hottest weeks of the year (when the mean temperature was 65 deg. F. or more) than in the coldest weeks (when it was 40 deg. or less). In the ventilated factories it was 8 per cent less. It is probable that thoroughly efficient ventilation may increase the average output of an unventilated factory by 12 per cent or more.

Ventilating Systems

At factory B, air douches were provided between each furnace and pair of rolls, but the air current was not powerful enough to extend in any strength to the legs and lower part of the bodies of the men. In factory A large fans, consisting of iron sheets about 6 ft. x 2 ft., revolved rapidly in a vertical plane midway between each furnace and pair of rolls, the bottom of the fan being about 7 ft. from the floor. This system could be improved by bringing in fresh air from outside. It should be possible to change the rate of speed of the fans to conform with seasonal temperature changes. Also, the rate of revolution of the fans should not be constant but rhythmical. Such rhythmic ventilation is more pleasant and efficient than steady ventilation.

In many American tinplate works cold air is driven up from the floor of the millhouses, but according to a workman who had experienced this system it was much less pleasant than the English system, as it produced chronic irritation of the skin of the legs. Again, in some American works the mill floor is cooled by running cold water through pipes inserted in the floor plates, and this method is said to be very efficient in keeping the millhouse cool.

Reducing Physical Exertion

The call upon the physical endurance of the millmen is so great that everything possible ought to be done to reduce it to its lowest limits. Lowering the furnace floor, rolls, tank and doubler's table would undoubtedly entail more bending on the part of the men, but the lack of uniformity in these heights in different factories suggests the need of further experimentation to determine the most suitable heights. Moreover, in American mills the rolls are several inches lower than in our mills, and this is said to be an advantage, not only because it entails less weight lifting, but because it enables the men to roll the iron with long tongs. The heaviest lifting of all is that of the doubler in returning the pieces to the furnace after their first rolling. The two together weigh 40 to 80 lb., and probably it would cause him less fatigue to lift them separately than conjointly, as is the present custom.

It is probable that some of the labor-saving devices employed in sheet steel mills might be adopted with advantage in tinplate mills. In the mills visited by the author the sheet steel was being rolled from bars weighing 40 to 100 lb., and when the sheets were put back into the furnace for re-heating they were not lifted from floor level, but were pushed up inclined steel rails running from floor to furnace mouth. The work of the behinder in raising the sheets of metal to the top of the roll for their return to the rollerman was greatly reduced by the use of a little platform on wheels. This was tilted down in front so that the metal sheet coming through the roll slid on to the platform, and then it was raised and pushed near to the upper roll, so that the sheet was caught and carried back. Again, the work of the doubler was reduced by having the shears absolutely at floor level, instead of on a table.

A much more important innovation than any of those mentioned is the so-called "double-manning" of the mills. This system, which is widely employed in America, consists in duplicating the number of men running each mill. The men work in relays and replace one another every few minutes. Thereby the rolls are kept much more fully occupied, and the men have much longer rest periods in which to recover. This system of double-manning has not yet been established in any English works, though its introduction is under consideration.

Practical Conclusions

The chief practical conclusions drawn by the author from his own investigations are two. Firstly, they confirm the importance of maintaining the agreement reached at the conference in 1913 and 1914 in

regard to introduction of cool air to reduce the temperature of the working places near the rolls and furnaces. Secondly, it suggests the importance of introducing changes in the clothing of the men. Before starting work, the men put on a short loose flannel shirt ending at the waist and open at the neck, and they thereby do what they can to keep the upper part of the body cool; but throughout the shift they wear the same trousers and pants in which they came to the works, and these garments are generally thick and woolen. If they were to put on gray flannel trousers without the pants they would keep much cooler and healthier. All tinplate workers taken together (other than those in the tinhouse) are two to five times more subject to rheumatism, rheumatic fever and neuralgia than any other manual workers such as brass casters, brass polishers, grinders and cutlers.

United States Foreign Trade in Glycerine*

AS A direct result of the war the United States trade in glycerine has been completely revolutionized. Imports ranging from 20,000,000 to 40,000,000 lb. annually for a decade and a half prior to 1914 dwindled to a little over 1,000,000 lb. in 1919; and the increase in the production of glycerine in the United States since the outbreak of the war has been such as not only to supply in large measure the enormously expanded domestic consumption but also to make possible the exportation of 21,000,000 lb. in 1918, and 13,000,000 lb. in 1919. (Before the war exports of glycerine, if any, were included with "all other chemicals"; but the increase in the exportation of glycerine was so great as to lead to its separate enumeration in 1918 in the statistical classification of exported merchandise.)

Imports of glycerine into the United States have formed a separate statistical schedule since 1884, and these imports, together with the average price per lb. are shown in Table I.

TABLE I

Fiscal Years Ending June 30	Lb.	Value	Average Price	Fiscal Years Ending June 30	Lb.	Value	Average Price
1884....	5,832,825	$679,818	$0.116	1902..	28,576,400	$2,358,325	$0.083

World Production—American Purchases

Glycerine was discovered by Scheele in 1779 when preparing lead plaster from olive oil, and was produced extensively in England, France and other European countries as a by-product of the soap and candle industries long before its manufacture was begun in the United States in 1847. In 1850 only 150 lb. of glycerine was produced in this country. Six years later glycerine was still comparatively rare, selling at $1.75 per pound.

The world production of crude glycerine prior to the war has been stated to be 40,000 tons per annum, 14,000 of which were from soap manufacture and 26,000 tons from stearine manufacture, of which England produced 5500 tons, France 3500 tons, the United States 3000 tons, and Germany 2000 tons from soap-making; and France 6000 tons, Germany and the United States 3000 tons each, Holland, Austria and Russia 200 tons each, with smaller amounts in other countries from the manufacture of stearic acid.

By 1884, imports of glycerine into the United States were of sufficient importance to be segregated from "all other chemicals" and, as stated, are shown separately in the import schedule thereafter. Notwithstanding wide fluctuations in both quantity and value from year to year, the import trade continued to grow until the high-record quantity of 41,181,526 lb. was reached in 1910, and the high-record value of $4,486,415 in the fiscal year ended June 30, 1914, immediately preceding the war.

The magnitude and value of this import trade in glycerine are evidenced from the total receipts in the period 1884-1919, amounting to 725,699,035 lb. of the aggregate value of $65,620,376.

Imports From Leading European Countries

From 1884 to 1910 France led as a supplier of glycerine to the United States, with the exception of the year 1900, when the United Kingdom sent a slightly larger quantity. England ranked first in 1911, 1912, 1913 and 1915, France again in 1914 and 1916; and in 1917 imports of glycerine from these countries ceased, to be resumed with shipments aggregating only 102,655 lb. from the United Kingdom in 1919. Other important European sources of glycerine since 1884 are given in Table II.

New Source of Supply

With the outbreak of the war the United States had naturally to seek other sources for a goodly part of such glycerine as it continued to import. Cuba had long been a shipper of glycerine to this country, and sent steadily increasing quantities each year from 1914 to 1918, but shipments declined somewhat in 1919. Canada contributed important amounts in 1914 and 1915, as did Mexico also, though there has been a decided drop in the shipments from the latter country to the United States dating from 1916 and shipments from the former entirely disappeared in 1918—to reappear, however, in 1919. Argentina and Brazil, and in lesser degree Uruguay, Venezuela and Japan, have been the chief new sources of supply. Details of this trade from 1914 to 1919 appear in Table III, the "eight European countries" being those for which data have already been given, namely, Austria-Hungary, Belgium, France, Germany, Italy, Netherlands, Spain and the United Kingdom.

In July, 1919, the United States imported 418,253 lb. of glycerine, valued at $45,061, or an average price of $0.108 a lb., contrasted with 233,660 lb. valued at $109,564, or $0.469 a lb. in July, 1918; in August, 231,791 lb., valued at $24,930, or $0.107 a lb., contrasted with 4,421 lb., valued at $1,348, or $0.305 a lb., in August of last year. For the eight months, January-August, 1919, imports of glycerine into the United States totaled 1,219,715 lb., valued at $184,839, or $0.151 a lb., against 1,080,920 lb., valued at $472,019, or $0.437 a lb., in the corresponding period of the calendar year 1918.

No accurate statistics are available showing the production of glycerine in the United States since the cen-

1916	.....	.....	1,754,537	.....	.....	898,855	2,553,486	858,854
1917	.....	.....	.....	.....	.....	499,124	792,555	.....
1918	.....	.....	.....	.....	.....	.....	.....	.....
1919	.....	.....	.....	.....	.....	.....	.....	102,655

sus taken in 1914. One of the war boards no longer functioning ventured an estimate of 70,000,000 lb. of crude glycerine as the domestic output in 1917.

The Bureau of the Census gives the production of crude glycerine for sale in the calendar year 1914 as 16,568,920 lb., valued at $2,278,976, but adds that figures are not available for the total production of crude glycerine, as that made and consumed in the manufacture of the refined glycerine was not reported. The refined glycerine made during the same year amounted to 60,944,799 lb., valued at $10,779,204. This glycerine was produced in 119 establishments, 19 of which were located in New York and the same number in Ohio, 12 in Illinois, 10 in Pennsylvania, 9 each in California and Massachusetts and the others scattered throughout the States.

Comparing these figures with the domestic exports of crude glycerine aggregating 21,045,991 lb. in the year ended June 30, 1918, and 13,018,882 lb. in the fiscal year 1919, while imports dropped to 1,875,531 lb. in the former year and to 1,171,679 in the latter, and in view of the well-known fact that enormous quantities of domestic glycerine were utilized in the increased manufacture of explosives in this country since 1914, it is evident that tremendous expansion in the recovery of crude glycerine has taken place in our domestic industries since the war began, no estimate of which would be more than guesswork until returns from the forthcoming census are available.

Growth of the Export Trade

As glycerine was not separately shown in the export schedule prior to the fiscal year 1918, a detailed study of the newly developed export trade in this commodity as disclosed by recent statistics is of interest.

Glycerine made in the United States was exported to 54 countries during the fiscal year 1918, 91 per cent of it going to Europe. The bulk of the 21,045,991 lb. exported in that year went to allied countries, Italy taking 18,886,974 lb., Canada 1,436,922, England 214,953, France 100,940, and Japan only 80,917.

Following the signing of the armistice there was a radical change in the destination of American exports of glycerine. Compared with the previous year, shipments to Italy show a sharp decline in 1919, none whatever having been made during the last half of the year,

TABLE III. IMPORTS OF GLYCERINE TO U. S. BY COUNTRIES

Imported from	Fiscal Years Ending June 30 — 1914 Lb.	1915 Lb.	1916 Lb.	1917 Lb.	1918 Lb.	1919 Lb.
Eight European countries	31,671,273	13,608,496	6,065,732	1,291,679	.....	102,655
Denmark	135,268	66,026	.....	.....	.....	.....
Russia in Europe	1,959,298	623,675	.....	.....	.....	.....
Switzerland	225,843	.....	650,856	223,367	.....	.....
Canada	1,324,594	1,436,209	845,822	34,661	.....	176,469

Venezuela	.....	.....	.....	.....	556	34,394
Japan	.....	.....	.....	80,000	42,520	.....
Total	36,409,619	17,620,509	10,621,403	4,122,410	1,875,531	1,171,679

while those to the United Kingdom and Japan materially increased. Larger amounts are also going to South America. Further, a movement to Oriental markets may be noted. The principal countries to which the domestic glycerine exported during the year ended June 30, 1919, went are as enumerated in Table IV.

TABLE IV. EXPORTS OF GLYCERINE FROM U. S.

Exported to	Lb.	Value	Exported to	Lb.	Value
United Kingdom	6,840,022	$3,873,393	China	66,485	$21,067
Japan	2,515,543	1,136,244	British India	42,858	11,951
Italy	1,713,636	937,144			
Canada	1,022,824	600,696	Total to countries named	12,695,853	6,710,236
Norway	262,930	57,926			
Argentina	143,994	37,775	Total to all countries	13,018,882	6,833,432
Cuba	87,561	34,040			

Nearly the whole of the amounts credited above to the United Kingdom and Canada was shipped prior to January, 1919. In normal times the British production of glycerine is more than sufficient to supply both England and Canada, while Italy finds a more convenient source of supply in France than in the United States, if its own production fails to fully meet all demands.

A decline in the United States export trade in glycerine during the last fiscal year is strikingly shown by comparing the total shipments for the first six months (July-December, 1918), amounting to 10,318,717 lb., valued at $5,927,028, with the 2,700,165 lb., invoiced at $906,404, for the second half, ending with June, 1919. That this decline, in comparison with corresponding figures for 1918, still continues is shown in the shipments for July and August, 1919, given in Table V.

TABLE V. EXPORTS FOR JULY AND AUGUST, 1919

Period	Lb.	Value	Average Price
July:			
1918	485,985	$245,164	$0.504
1919	67,980	15,659	.230
August:			
1918	570,405	340,768	.597
1919	391,154	82,956	.212
Eight months ending August—			
1918	12,492,401	6,425,540	.514
1919	3,158,899	1,005,019	.318

While the production of glycerine is not confined to any one section of the country, exports for the fiscal year 1918 cleared chiefly from the ports of Baltimore and New York, 79 per cent of the total quantity shipped to all countries passing through the Maryland district and 13 per cent through New York. Of the 2,700,165 lb. of glycerine exported during the six months ended June, 1919, 1,277,828 lb., valued at $323,464, was shipped through the customs district of New York; 488,918 lb., worth $107,891, from San Francisco; 769,993 lb., invoiced at $406,941, through Washington; and smaller amounts through other districts, none, however, passing through Maryland.

Exchange a Factor—Average Prices

A factor of prime importance to be considered if the United States is to maintain an export trade in glycerine is the difference in the rate of exchange. It is stated that the present rate is such as to make the purchase of foreign glycerine possible in this country at a price considerably below domestic quotations. This seems to be borne out by the increased imports at lower average prices, and decreased exports in July, August, and the eight months ended with August, as compared with corresponding figures for 1918.

Import prices in American official statistics are based on the actual market value or wholesale price at the time of shipment to the United States in the principal markets of the countries from which imported, including values of all containers and coverings. Export prices are based on the value of the article at the time of exportation at the ports in the United States from which shipped.

The average annual import price of glycerine in 1884 was $0.116 a lb., dropping to $0.06 the following year and to $0.056 in 1886 as imports continued to increase, reaching the low record of $0.054 in 1893. Considerable variation thereafter is shown in the price from year to year, but always below $0.10 per lb., until 1911, when it reached $0.109, with a further rise to $0.123 in 1914 just prior to the war. From 1915 to 1916 imports of glycerine decreased 7,000,000 lb. and the price rose from $0.124 to $0.210 a lb. Further declines in the quantity imported brought the annual average price up to $0.315 in 1917, and the high record of $0.429 a lb. in 1918, when the total importation was less than 2,000,000 pounds.

Although imports of glycerine during the fiscal year 1919 show a further decline of 700,000 lb. as compared with the previous year, the close of the war is marked by a drop to $0.318 in the average import price. These average annual prices, covering as they do all grades of commercial glycerine, give no idea of the actual market fluctuations from the highest to the lowest prices on single shipments during shorter periods; and the same applies to exports during the war period, when prices shown on invoices for export ranged from $0.18 to $1 a lb. for domestic glycerine. Prices of chemically pure and dynamite glycerine were quoted as high as $0.70 per lb. in the New York market during the latter months of 1917, and as low as $0.20 per lb. for chemically pure and $0.17 for dynamite glycerine at the end of 1918.

Effect of War's End on Prices

The close of the war released for industrial purposes glycerine formerly used in the manufacture of high explosives. The resulting competition among the nations caused a sharp decline from war prices of both imports and exports, the extent of which is shown in the months of July and August and the eight-month period ending August, 1919, as compared with corresponding data for the previous year.

The monthly average import price of glycerine declined from $0.469 in July, 1918, to $0.108 in July, 1919, receipts being nearly doubled in quantity; and from $0.305 in August, 1918, to $0.107 in August, 1919. The average import price for the eight-month period ending in August, 1918, was $0.437, as compared with $0.151 for the corresponding period in 1919.

There was 21,045,991 lb. of glycerine exported during the fiscal year 1918 at an average price of $0.503 a lb., compared with 13,018,882 lb. in 1919 at $0.525. July, 1919, shows a decline to $0.23 a lb., as compared with $0.504 in 1918; and August, 1919, $0.212 as compared with $0.597 in the corresponding month of 1918. For the eight months ended with August, 1918, the average export price was $0.514, dropping to $0.318 during the corresponding period of 1919.

Varied Uses of Glycerine

By far the largest application for glycerine is for the manufacture of nitroglycerine. The combination of nitroglycerine with nitrocellulose, or guncotton, forms a more recently developed class of high explosives known as blasting gelatine, cordite, etc. Glycerine is also employed extensively for filling hydraulic jacks, gas meters, and tubes liable to be exposed to great cold, and in the manufacture of toilet soaps, inks, waterproof paper, preservatives for food products, "sizes" for textiles, for the production of plastic masses, such as printing rollers and hectograph mass, and in the treatment (scheelizing) of wine, beer and vinegar. The bulk of the distilled glycerine is employed in the manufacture of dynamite and other high explosives and the commercially pure product in pharmacy and medicine. In medical practice nitroglycerine is for the treatment of angina pectoris.

Proposed "Efficiency Exhibition" in London

The London *Daily Mail* proposes to hold an Efficiency Exhibition at Olympia in February, 1920. It is intended that every machine, method or system that can save labor, time and materials shall be represented. The demonstration will cover the farm, the counting house, factory, office and warehouse. Support has been promised by a number of organizations, including the Federation of British Industries, the British Science Guild and the Electrical Development Association.

Legal Notes

By Wellington Gustin

Legality of Resale Prices—Manufacturers' Rights Under the Sherman Act

THE RIGHT of a manufacturer to make and maintain the resale price of his products has been upheld in the latest case on the proposition decided in the United States Supreme Court. The manner and methods pursued in establishing resale prices has been the subject of various attacks by the Federal Government in prosecutions under the "act to protect trade and commerce against unlawful restraints and monopolies," known as the Sherman anti-trust act. From this decision it would seem that the manufacturer may announce in advance under what conditions it will deal or sell its products, and it is perfectly within its rights in refusing to sell to those who cut the prices. But the manufacturer cannot go further and enforce any agreement that would uphold the resale prices, that is, the dealer may actually resell at any price he chooses. The court undoubtedly would not uphold any action the manufacturer might institute against the dealers, but it does extend to it his common law right to refuse to deal with them further.

In the present case of the United States vs. Colgate & Co. (39 Sup. Ct., 465) an indictment was returned charging the defendant company with a violation of the Sherman act. The indictment ran only against the company and not against any of the dealers handling its products.

The trial court held that the indictment should set out such facts as to make it clear "that a manufacturer, engaged in what was believed to be the lawful conduct of its business, has violated some known law before it can be haled into court to answer the charge of a commission of a crime," and held that this indictment did not in substance charge any offense under the Sherman act or under any other law of the United States. Hence the indictment was quashed by the trial court and counsel for the Government appealed to the Supreme Court.

Indictment Was for Unlawful Combination of Manufacturer and Dealers

This indictment proceeded upon the theory of an unlawful combination of the manufacturer and the dealers, and made no reference to monopoly. The charges were in vague and general language, but perhaps presented the case with as much certainty and definiteness as the facts warranted. After setting out the company's general methods of doing business in the sale and distribution of its products, the material part of the indictment alleged the following:

"During the aforesaid period of time, within the said Eastern District of Virginia and throughout the United States, the defendant knowingly and unlawfully created and engaged in a combination with said wholesale and retail dealers, in the said Eastern District of Virginia and throughout the United States, for the purpose and with the effect of procuring adherence on the part of such dealers (in reselling such products sold to them aforesaid) to resale prices fixed by the defendant, and of preventing such dealers from reselling such products at lower prices, thus suppressing competition amongst such wholesale dealers, in restraint of the aforesaid trade and commerce among the several States in violation of the act entitled 'An act to protect trade and commerce against unlawful restraints and monopolies,' approved July 2, 1890."

It charged the purposes of the combination were accomplished by the distribution of letters, telegrams, circulars, and lists showing uniform prices to be charged, among the dealers, urging these to adhere to such prices; and notices, stating that no sales would be made to those who did not; requests for information concerning dealers who had departed from the prices specified; investigation and discovery of those not adhering thereto, and placing their names upon "suspended lists"; requests sent to offending dealers for assurances and promises of future adherence to prices, which were often given; uniform refusals to sell to those who did not; similar assurances and promises required of, and given by other dealers, followed by sales to them; while there were unrestricted sales to dealers who had observed the specified resale prices.

By the employment of these methods and means, the indictment charged, wholesalers in the company's products throughout the United States, with few exceptions, resold their goods at uniform prices fixed by the defendant, and refused to resell the products to retail dealers at lower prices. In turn, because of these things the retailers throughout the United States resold the products to the consuming public at the uniform price fixed by the company. In this manner competition in the sale of the products was suppressed, thus maintaining and enhancing the prices of such products to the retail dealers and the consuming public.

Was This a Violation of the Sherman Law?

The question for answer by the Supreme Court was the interpretation placed upon the indictment by the trial court, and thereupon to determine whether, so construed, it fairly charges violation of the Sherman act. The counsel for the Government contended that, as interpreted, the indictment adequately charged an unlawful combination within the doctrine stated in the case of Miles Medical Co. against Park & Sons Co. (31 Sup. Ct., 376), such unlawful combination resulting from restrictive agreements between defendant and sundry dealers whereby the latter obligated themselves not to resell except at agreed prices. However, in the Miles case the unlawful combination was effected through contracts which undertook to prevent dealers from freely exercising the right to sell.

The defendant company contended against this view and maintained that the trial court's opinion construed the charges as alleging only recognition of the manufacturer's right to specify resale prices and of refusal to deal with any one who failed to maintain these prices. A part of this opinion said that no charge was made that the company entered into any contract with any of its retail dealers in restraint of interstate trade and commerce, but the charge, in effect, was that it unlawfully created and engaged in a combination with certain of its wholesale and retail customers to procure adherence to resale prices fixed by the company which resulted in enhancement and maintenance of such prices, suppression of competition, etc. The view of the trial court was that the question was fairly presented of whether a manufacturer of products shipped in interstate trade is subject to criminal prosecution "for entering into a combination in restraint of such trade and commerce, because he agrees with his wholesale and retail customers upon prices claimed by them to

be fair and reasonable, at which the same may be resold, and declines to sell his product to those who will not thus stipulate as to prices. This, at the threshold, presents for the determination of the court, how far one may control and dispose of his own property, that is to say, whether there is any limitation thereon, if he proceeds in respect thereto in a bona fide and lawful manner. That he may not do so fraudulently, collusively, and in unlawful combination with others may be conceded. But it by no means follows that, being a manufacturer of a given article, he may not, without incurring any criminal liability, refuse absolutely to sell the same at any price, or to sell at a named sum to a customer, with the understanding that such customer will resell only at an agreed price between them, and should the customer not observe the understanding as to retail prices, exercise his undoubted right to deal with such person. . . .

ANY DEALER IN REALITY FREE TO SELL AT ANY PRICE HE CHOSE

"No suggestion is made that the manufacturer attempted to reserve or retain any interest in the goods sold, or to restrain the vendee in his right to barter or sell the same without restriction. The retailer after buying could, if he chose, give away his purchase or sell it at any price he saw fit, or not sell it at all, his course in these respects being affected only by the fact that he might by his action incur the displeasure of the manufacturer, who could refuse to make further sales to him, as he had the undoubted right to do. There is no charge that the retailers themselves entered into any combination or agreement with each other, or that the defendant acted other than with his customers individually."

MANUFACTURER MAY REFUSE TO SELL TO ANY RETAILER

The purpose of the Sherman act, said the Supreme Court, is to prohibit monopolies, contracts and combinations which probably would unduly interfere with the free exercise of their rights by those engaged or who wish to engage in trade and commerce. It aims to preserve the right to freedom to trade. In the absence of any purpose to create or maintain a monopoly, the act does not restrict the long recognized right of trader or manufacturer, engaged in an entirely private business, freely to exercise his own independent discretion as to parties with whom he will deal; and of course he may announce in advance the circumstances under which he will refuse to sell, said the court. Quoting from another case the court said: "A retail dealer has the unquestioned right to stop dealing with a wholesaler for reasons sufficient to himself, and may do so because he thinks such dealer is acting unfairly in trying to undermine his trade."

The affirmation of the judgment of the lower court was a vindication of the company in the manner and methods employed by it in attempting to maintain its resale prices. However, it will be noted it was not charged with selling its products to dealers under agreements which obligated the latter not to resell except at prices fixed by the company.

THE SCHRADER CO. CASE

Judge Westenhaven in the U. S. District Court for Ohio has just quashed an indictment returned by the Federal Grand Jury against A. Schrader's Son, Inc., for having entered into certain contracts with the tire maker and jobber for the handling of its goods, which contracts fixed the prices at which the tire maker might sell to the jobber, retailer and consumer, and the jobber might sell to the retailer and consumer.

The Government contended that the entering into these contracts was an offense under the Sherman act, and that the case was not controlled by the decision of the Supreme Court in the Colgate case, which held, among other things, that a manufacturer could choose his own customers and announce in advance that it would deal only with such customers as maintained the prices fixed by the said manufacturer.

The contention of the Schrader company was that there was no essential difference between its selling plan and that of the Colgate company, and that the mere fact that it announced its prices in a written license agreement which was signed by the tire makers and jobbers did not bring the case within the Sherman act.

The decision of Judge Westenhaven was in effect that the charges in the Schrader indictment did not constitute a crime under the Sherman anti-trust act, and the indictment was accordingly dismissed.

Measure of Damages for Failure to Deliver Specified Quantity of Goods

The measure of damages for failure to deliver a specified quantity of goods as agreed was decided in the case of De Greeff against the Franco-American Chemical Co. (174 N. Y. S., 70). Plaintiff sued for breach of defendant's agreement to deliver certain goods under a written contract which called for delivery during March. The delivery was made on April 6, and was short about five tons. In reply to plaintiff's protest against the shortage of the goods, the defendant consistently and persistently maintained that it would not furnish the balance. Since it chose to break its contract, the measure of damage recoverable against it is the difference between the contract price and the market price of the amount of goods undelivered at the time and place of the delivery called for by the contract or selected by the parties by a subsequent valid agreement.

The trial judge admitted in evidence the range of prices of the goods undelivered, up to June, which was two months after the breach of the agreement. The Supreme Court held this to be unjustified, it appearing that there was a ready market for the goods at all times, and that the market price at the time of the breach varied but little, if at all, from the contract price.

The jury having found that defendant was in default, the plaintiff was entitled to be compensated for his loss, said the court, but he was not entitled to speculate at defendant's expense on the course of the market for two months after the default occurred.

New Process for Converting Ore Into Metal

A Norwegian firm, A/S Norsk Staal (Elektrisk-Gas-Reduktion of Christiania) worked out, during the war, a general process for reducing tungstic acid into tungsten powder and molybdenum sulphide into metallic molybdenum. It claims that the final products, which are in the form of small tablets, are of the most superior quality, being completely free from sulphur, carbon, or oxygen. It also says that the cost of converting the ores into metal is lower than by any other method known by it.

A New Plug Valve

ONE of the recent developments in chemical accessory apparatus of vital importance to the industry is a non-stick lubricated plug valve.

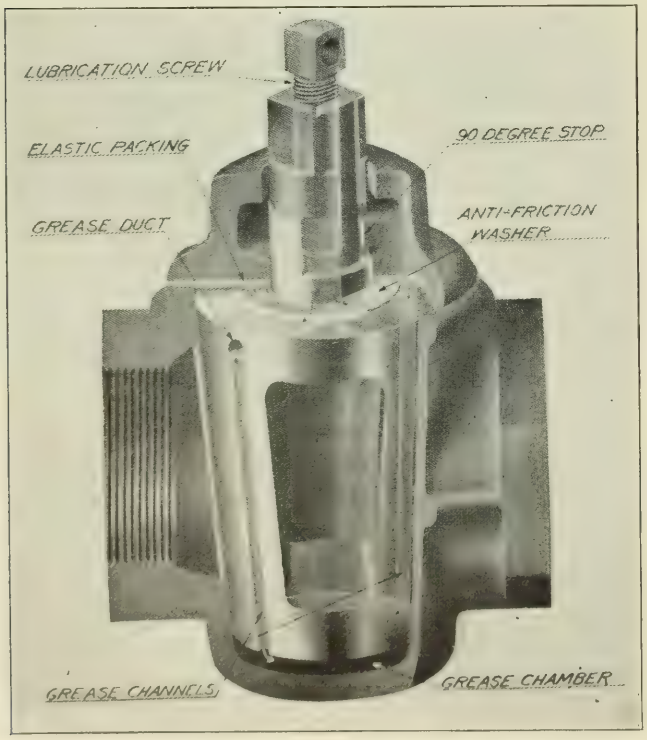
A plug valve is the logical type for use in pipe lines handling slimes, slurries containing abrasive materials and all other liquors where solid materials are carried in suspension. The difficulty of using this type has been, however, that the bearing surfaces of the valve have rapidly corroded, causing the plug to stick and resulting in high breakage costs when workmen attempted to keep the valve in operation. This has been particularly true in the operation of cyanide plants, and it was to do away with this trouble that the Nordstrom lubricated plug valve was first designed and placed on the market by the Merrill Co. of San Francisco. Its basic principle is the combination in a plug valve of lubricant conduits, and a lubricant chamber at the base of the plug, so positioned that when pressure is applied to the lubrication screw, this pressure operates to lift the plug from its seat and simultaneously to distribute lubricants over the bearing surfaces. A flexible packing is provided between the body of the valve and the cover. This packing also rests upon an anti-friction washer forming the thrust bearing of the plug, which is grooved concentrically to prevent leakage.

The flexible packing furnishes the necessary elasticity to allow the plug to be forced from its seat for the purposes of lubrication and to force the plug back into its seat when the pressure in the lubricant chamber is released. A stop is cast as an integral part of the plug and cover and is so positioned that the lubricant conduit can never be exposed to the fluid passing through the valve.

An investigation of this valve in operation has shown that no matter how firmly the plug may be stuck to the body of the valve, when force is applied to the lubricating screw, a pressure is created in the grease chamber at the base of the plug and this pressure must either raise the plug from its seat or break the body of the valve. This screw may be turned even in the 6- and 8-in. sizes by the application of an ordinary 18- or 24-in. monkey wrench.

The protective coating of lubricants on the bearing surfaces insures a tight fit at all times.

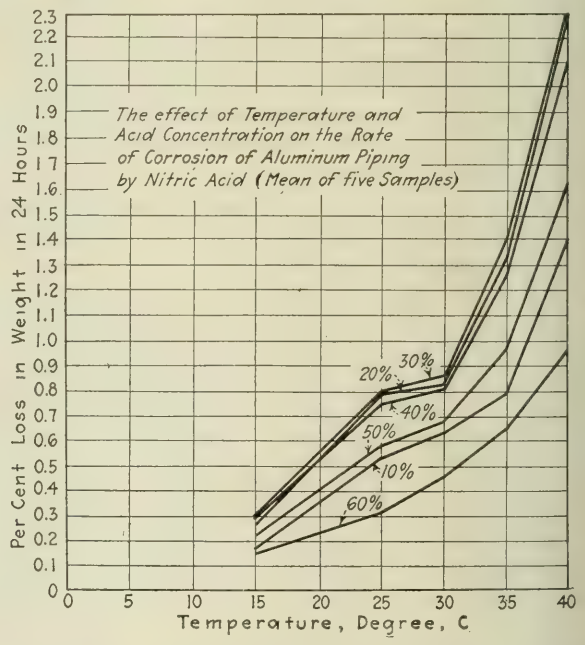
These valves may be made from any acids or alkali-resisting metals, such as Duriron, aluminum, ceramic ware. Such a piece of apparatus should prove a boon to many operators in chemical plants in maintaining the flow of important fluids through the processes.



NON-STICK LUBRICATED PLUG VALVE

Acid-Resisting Qualities of Aluminum

A SERIES of experiments recently conducted have shown that aluminum metal makes a good material for use around nitric-acid towers and as piping for the construction of the acid lifts. After considerable work by the producing companies it has been found that aluminum can be manufactured on a commercial basis with a purity in excess of 99 per cent.



The effect of Temperature and Acid Concentration on the Rate of Corrosion of Aluminum Piping by Nitric Acid (Mean of five Samples)
Per Cent Loss in Weight in 24 Hours
Temperature, Degree, C
20%
30%
40%
50%
10%
60%

Contrary to the usual belief, the corrosion of aluminum piping by nitric acid is in more direct proportion to the temperature and not affected by the concentration; in fact, the higher the concentration the less the corrosion, temperature being the same in both cases. This is very clearly shown in the accompanying figure.

In making up the curves shown, five pieces of 1-in. aluminum pipe were selected at random and immersed in the acid concentration designated for each curve. The first set of experiments was made at room temperature averaging about 15 deg. C. After this, runs were made at 25 deg. C., 30 deg. C., 35 deg. C. and 40 deg. C. In the experiments at room temperature the corrosion tests were continued for 21 hr. per day for five days, the test pieces being weighed each day. In the runs at higher temperatures five 6-hr. periods were used, weighings being made after each 6-hr. period. This procedure eliminated errors and made

certain that the behavior of each piece of pipe was substantially uniform.

It is therefore concluded that where piping is used for acid lifts they should be immersed in a well continually overflowing with running water. The trouble with the use of aluminum, however, for acid lifts is not so much on account of the corrosion feature as because of the short life of rubber gaskets which are used between the joints of piping in the construction of lifts. Duriron or high-silica iron connections should be used in all cases.

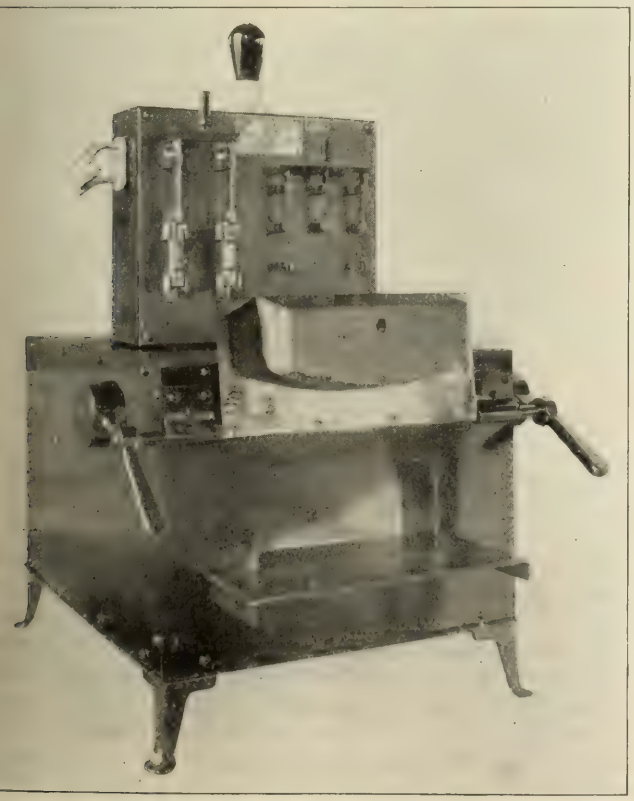
An alloy has recently been prepared by the Chemical Equipment Co. consisting of aluminum and a small percentage of some of the rare earths, the formula being secret. This alloy is known as No. 78 and has the following physical properties:

Weight, lb. per cu.in.	0.09
Yield point, lb.	9,530
Tensile strength, lb. per sq.in.	18,040
Elongation, per cent in 2 in.	2.5
Reduction of area, per cent	5.3

The percentage of aluminum contained in this alloy is about 96. It has been found a perfect metal for resistance against the action of acetic acid. Tests have been made by immersing a bar having a total surface of 34 sq.cm. weighing about 30 g. in 70 per cent of acetic acid for 46 hr. at room temperature, and then bringing the solution to a boil for 5 min. and allowing to cool for 2 hr. The loss in grams per sq.cm. was 0.00006. This metal is used by the company in the construction of acid-resisting equipment.

Electrically-Heated Laboratory Metal Furnace

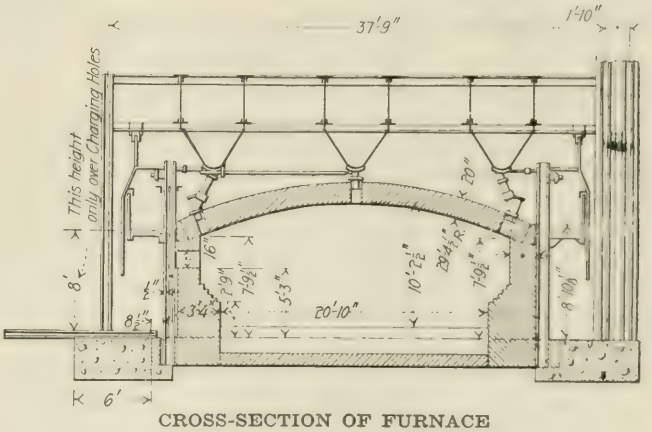
The General Electric Co. has designed and placed on the market an electrically-heated metal furnace for use in laboratories where heat of 1560 deg. F. and below are required on control and research work. This furnace is lined with fireclay and has inside dimensions of 15 in. long x 8½ in. wide x 4½ in. high. The current consumed at the maximum heat is 4 kw. and at the secondary heat, 2 kw. The heat is hand controlled and an indication lamp is provided on the top of the furnace for showing when the full amount of current is turned on. The accompanying illustration gives a general idea of the design, the metal parts consisting of sheet iron and malleable castings. A slate panel is mounted on the top and is an integral part of the furnace. This panel mounts switches for controlling the temperature as shown. The refractory door is counterweighted with handles for opening at either end of the furnace.



METAL FURNACE, ELECTRICALLY HEATED, FOR LABORATORIES

Synopsis of Recent Chemical and Metallurgical Literature

Furnace for Converter Slag.—A large reverberatory furnace was erected on the converter floor at the Washoe smelter about three years ago, whose operation is to be described by FRED LAIST and H. J. MAGUIRE, of the Anaconda staff, before the forthcoming meeting of the Mining & Metallurgical Engineers.



CROSS-SECTION OF FURNACE

The figure shows a cross-section; it is 153 ft. (46 m.) long inside, with rectangular hearth, the roof being drawn down at the skimming end. The flue is 6 ft. wide x 8 ft. 6 in. high (2.5 x 1.8 m.). Three-side doors are provided near the firing end of the furnace through which hot slag can be laundered; two matte taps are about 25 ft. (8 m.) from the other end; skim line is 18 in. (45.7 cm.) above furnace bottom. It is equipped with hoppers on both sides for the fuel length, and down the center for 100 ft. Five pulverized coal burners, using 16-oz. air, supply the fuel. Immediately over and opposite the slag-charging spout the hopper carries concentrates; from this point back to the burners the sides are banked with special (high S) calcine, and thence forward the banks are siliceous material. In operation the sulphur in calcine reduces Fe_2O_3 and Fe_3O_4 in converter slag to FeO, which is slagged by silica from the banks to produce a slag containing not less than 30 per cent silica; calcine also provides matte for washing disseminated globules of white metal from the slag. The slag is charged from 9-ton ladles at intervals of 15 min., a small stream of free concentrate dropping into the furnace just over the inflowing liquid.

Two Stirling boilers, type M, rated at 865 hp. each, are placed in a double 15 x 13 ft. (45 x 3.9 m.) flue leading from the furnace in such a way that either or both may be operated. Cooled gases are then discharged through a brick-lined 12 x 200 ft. (3.6 x 60.9 m.) steel stack, connection to the main flue system not being available without extensive and costly construction. Skimming block and magnesite-lined slag launder are both water cooled, while the cast-iron tap hole plates are set in a long, narrow water jacket.

Results for July, 1918, are tabulated below:

PER CENT BY WEIGHT OF MATERIAL TREATED

	Total Tons	Daily Average	Per Cent
Converter slag	16,813.0	54.2	54.5
Concentrate	1,748.0	56.4	5.7
Calcine	11,681.1	376.8	37.9
Tailings	595.7	19.2	1.9
Total	30,838.1	994.7	100.0
Coal burned	2,436	78.6	.....
Coal ratio, to whole charge			1:12.66
Coal ratio, to solid charge			1:5.76

Analyses

	Converter Slag	Furnace Slag	Calcine	Concentrate
SiO_2	23.3	34.1	30.8	19.2
Cu	3.95	0.55	7.85	7.64
FeO	61.2	53.3	36.3	37.9
S	0.8	....	8.8	35.6
CaO	0.1	1.7	3.3	0.1
Al_2O_3	5.9	....	5.9	4.2

Copper in all material treated, lb.	3,459,448
Copper in all converter slag, lb.	1,328,227
Copper in all other material, lb.	2,131,221
Silica to slag, lb.	17,232,647
Slag produced, tons	25,268
Copper in slag, lb.	277,948

Recovery of copper based on silica balance, 91.97 per cent

Average cost for 1918 = 61c. per ton of converter slag, less credit of 26c. for waste heat power.

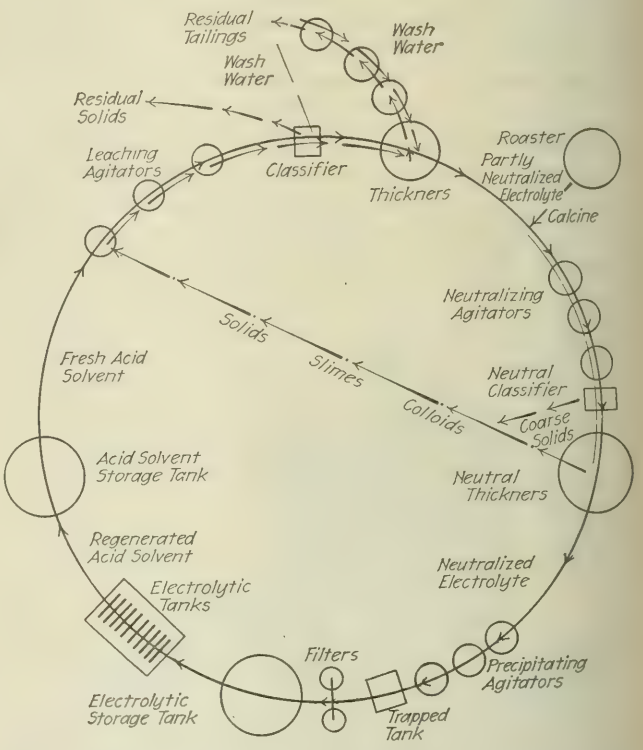
In a run of 409 days ending early in 1919 the waste slag averaged 0.57 per cent copper. This is equivalent to an increase of only 0.05 per cent in the copper content of all of the reverberatory slag produced, and is probably fully as good a result if not better than if the converter slag had been spread uniformly through all of the furnaces.

Magnetic Analysis.—R. L. SANFORD and WILLIAM B. KOUWENHOVEN describe a testing machine designed to locate flaws in rifle-barrel steel by magnetic analysis, in Scientific Paper 343 of the Bureau of Standards. Their method is similar to that of Burrows' for steel rails (See MET. & CHEM. ENG., vol. 17, p. 130), and mounts the bar to be studied vertically, as a solenoid core, the counterweighted coils moving along it as a guide. Mounted within this magnetizing solenoid is a test coil by means of which variations in magnetic flux within the bar can be measured. For uniform bars, no electromotive force will be induced in the test coil; if, on the other hand, the permeability is not constant, the flux will vary and an induced electromotive force will be indicated by a galvanometer in circuit. Records were automatically made by photographing a beam of light from the galvanometer mirror in an oscillograph.

Experiments showed that a flux density of 15,000 gausses and a travel of 6 in. per sec. with a short-period (1-sec.) galvanometer gave best results. Great difficulty lies, however, in the interpretation of the results, and while many bars in a lot rejected on account of pipes were examined, not a single pipe was discovered in drilling samples for which records of magnetic uniformity had been obtained. The sensitivity must be reduced to prevent rejection of satisfactory material, and the record which indicates a pipe is still to be determined.

Recent Chemical and Metallurgical Patents

Process for the Extraction of Zinc.—R. H. STEWART, of Vancouver, B. C., and S. G. BLAYLOCK, ROBERT VAUGHAN and J. K. BATCHELDER, of Trail, B. C., have been granted a patent for the hydrochemical extraction of zinc from ores or other zinc-containing material in which the zinc has been made soluble by roasting. This patent covers the process in use at Trail, B. C., by the Consolidated Mining & Smelting Co. of Toronto, Canada. In order to obtain a coherent deposit of zinc on the cathodes of an electrolytic cell, it is essential that metal electro-negative to zinc be removed from the electrolyte. This is usually accomplished by precipitating these metals on metallic zinc in a neutral or nearly neutral solution. The zinc and precipitated metals are removed from solution by filtration and the solution is delivered to the electrolytic tanks. This neutralization is accomplished by pulverized limerock, zinc hydrate or other base. In the process described, however, the neutralization is accomplished by agitation with freshly roasted zinc



ore or calcine. The use of the solution is cyclical; being delivered to the neutralizing agitation tanks from a preceding operation, it does not contain a sufficient amount of acid to remove all the soluble zinc. The pulp from the agitation tanks, which consists of neutralized solution and suspended solids, passes from the agitation tanks to a classifier, where the coarse solids are removed, thence to a continuous decantation thickener, in which the solution is separated from slimes and colloids. The coarse solids, slimes and colloids are delivered to leaching agitators. The neutral solution is treated in agitating tanks with metallic zinc, freed from zinc and precipitated metals by means of filter presses and the solution

delivered to storage tanks for use in the elctrolytic zinc cells as desired. Sulphuric acid is regenerated on the electrolytic tanks and the acid electrolyte depleted in zinc is delivered from the electrolytic cells to a storage tank. From this tank the acid solution is delivered to the leaching agitators previously mentioned, together with the solids, slimes and colloids from the classifier and thickeners. The remaining soluble zinc is dissolved and the acid in solution partly neutralized. The solids are removed from the solution and washed by a second classifier and set of thickeners; the solution and wash water pass on to the neutralizing agitators, where it is again treated with calcine, completing the cycle. The solid from the thickeners is discharged to the dump. In the accompanying sketch the cycle of the solution is shown by the full line circle, the flow of solids by the dash and dot lines, and the wash water by the broken lines. (1,320,805; Nov. 4, 1919.)

Method of Obtaining Pure Tungsten.—JOHN B. EKELEY and W. B. STODDARD, of Boulder, Col., produce pure sodium tungsten from wolframite, hubnerite, ferberite, scheelite, tungstite or other ores of tungsten as follows: The ore is crushed and ground to a suitable degree of fineness, depending upon the facility with which it responds to subsequent treatment, and mixed with salt, sodium carbonate and, if necessary, silica. Sufficient carbonate is added to combine with all the tungstic acid and leave an excess; sufficient silica must be present to combine with the excess of carbonate. With some ores sodium nitrate or chlorate is added to provide an oxidizing agent. This mixture is fused in a suitable furnace. The fusion is cooled, crushed and lixiviated with twice its weight of water. The sodium tungstate is soluble and the solution in addition contains compounds of phosphorus and arsenic. The solution is heated and magnesium chloride or nitrate added in excess of the amount necessary to precipitate $MgHPO_4$. The solution is then boiled. To the boiling solution is added a mixture of sodium hypochlorite and ammonia. This precipitates almost immediately all but minute traces of arsenic and phosphorus from the solution. In addition to the sodium tungstate the solution will contain sodium chloride and small amounts of carbonate and sulphates. The precipitate is filtered from the solution and treated with a fresh charge of ore. Arsenic and phosphorus do not accumulate in the process, since the larger portion of the elements are removed in the slag of the fusion furnace. (1,322,485; Nov. 18, 1919.)

Treatment of Zinc-Bearing Ores for Recovery of Zinc by Electrodeposition.—The usual methods of purifying zinc sulphate electrolyte by treatment with limestone for the removal of iron and other impurities and with zinc dust for the removal of silver, copper, cadmium, antimony and arsenic do not remove cobalt. This element adversely affects the electrodeposition of zinc from this solution, but where cobalt has not accumulated to more than 200 to 300 mg. per liter this deleterious effect can be overcome by the addition of glue. In solutions containing up to 100 mg. cobalt per liter, 5 lb. glue per ton of zinc produced is required and it is desirable to add 1 lb. glue for each additional 50 mg. cobalt per liter present. When the amount of cobalt has accumulated in excess of 300 mg. per liter, it becomes necessary to remove this element from the electrolyte. This may be accomplished by adding to the solution 1.5 mg. copper as sulphate and 1.5 mg. arsenic as sodium arsenate for each milligram cobalt present and then agitating with from 8 to 10 times the quantity of zinc dust as there was copper added. This purification is carried out at a temperature of 75 deg. C. and removes cobalt and other impurities effectively. (H. W. GEPP, DAVID AVERY, R. H. STEVENS and H. W. SNOW. Assigned to Electrolytic Zinc Co. of Australia Proprietary, Ltd., of Melbourne, Australia. 1,322,104; Nov. 18, 1919.)

Hardening After Long Reheating.—GABRIEL VAN OORDT, of Basel, Switzerland, has found that many alloys and pure metals, when reheated to a certain moderate temperature (characteristic for each composition) for several days or weeks, convert castings or forgings which are machined with difficulty into pieces which cut satisfactorily, yet have a higher tenacity and hardness. Prolonged heating to a lesser temperature produces only a partial hardening. As instances of his patented method he cites the following:

Alloy	Original hardness	Reheat	Time	Subsequent hardness
85 Al : 15 Zn	50	70° C.	5 days	92.6
98 Al : 2 Cu	32.7	160°	10 days	55.3
Zn	35	300°	1 day	39.0
Cu	30	200°	20 days	42.9
72 Cu : 28 Zn	41.2	300°	3 days	47.4
Fe	85.7	300°	50 days	104

(1,326,775, assigned to Société Anonyme des Usines Giulini, Basel; Dec. 30, 1919.)

Combination Converter and Electric Furnace.—A side-blown converter is patented by P. F. SARRON and JULES SIMON, of Lyons, France, having a hinged door over the mouth, and two large removable plugs closing corresponding openings through the lining and shell between wind box and mouth. After a blow is completed in the ordinary way, the converter is tipped over horizonally, the mouth tightly closed, and the plugs, now on top of the shell, replaced by electrodes, with proper holders and operating mechanism. In this way the vessel is quickly converted into an electric furnace for final refining. (1,325,114; Dec. 16, 1919.)

Regeneration of Pickling Solution. — WILLIAM FEENIE of Buhl, Minn., and WILLIAM W. RHODES of Wilmington, Del., note that a pickling bath of sodium bisulphate solution gives a better surface for many uses than sulphuric acid, but the solution becomes inactive before all the reagent is consumed, resulting in a large waste in chemicals. The activity may be regenerated by decreasing the ratio of normal sulphates (especially of sodium) to the bisulphates, most easily done by cooling from 60 deg. C., the usual working temperature, to 30 deg. C., when a large portion of Na_2SO_4 and a smaller amount of $FeSO_4$ will salt out. (1,326,585, assigned to E. I. du Pont de Nemours & Co.; Dec. 30, 1919.)

Melting Light Scrap in Acid Open-Hearth.—SIR ROBERT HADFIELD, of Westminster, England, patents a method of melting turnings in an acid open-hearth without adding pig iron and without damage to the furnace. As an instance he covers the hot bottom with crushed slag from a previous heat, and then with a layer of equal parts of 50 per cent ferrosilicon and anthracite crushed to ¾ in. (2 cm.). Nine tons (9,100 kg., or one-third the charge) of turnings was then quickly charged and melted to protect the loose material from oxidation and the remainder of the charge

introduced over a period of four hours. Immediately before each batch was charged, a layer of the ferro-carbon mixture was spread on the banks, and after the final melting, a layer of fine anthracite thrown around the edge of the bath. About 550 lb. (250 kg.) of Cumberland iron ore was introduced just before the charge came to boil, and the boil maintained until the carbon was as low as necessary; then being stopped with the usual addition of ferrosilicon. Ferromanganese was then added to desulphurize. (1,326,861; Dec. 30, 1919.)

Personal

E. M. Bond, formerly metallurgist and chemist of the American Platinum Works of Newark, N. J., has resigned to assume similar duties with the Interstate Smelting & Refining Co., Newark, N. J.

Elmer H. Bunting has accepted a position as research associate in ceramics at the University of Illinois.

Dr. Charles E. Caspari, professor of chemistry at the St. Louis College of Pharmacy, has just been elected chairman of the St. Louis Section of the American Chemical Society and will have charge of the general arrangements for the national meeting to be held in St. Louis, April 13 to 16.

E. B. Clark, formerly in the laboratory of the Ward Baking Co., New York City, is now chief chemist of the Omaha Flour Mills Co., Omaha, Neb.

H. S. Emlaw has been appointed general manager of the American Trona Corp. in California, and Frederick Vieweg assistant general manager.

Leo Finkelstein has resigned his commission as lieutenant in the Chemical Warfare Service and has resumed duties as instructor in chemistry at the University of Chicago.

N. J. Gothard has resigned his position in the laboratory of the Sanitary District of Chicago to accept a position with the Sinclair Refining Co., East Chicago, Ind.

Dr. A. O. Lundell has become associated with the Allbright-Nell Co., manufacturer of packing house machinery and equipment. Dr. Lundell has been in the U. S. Bureau of Animal Industry Service for fifteen years, and has been prominent in the development of mechanical packing house equipment for the conservation of meat food products.

Dr. C. S. Miner read a paper on "The Verification of Percentage Formulas" before the annual convention of the Association of Feed Control Officials at Washington recently.

Dr. H. W. Morse has resigned from the position of technical manager of the American Trona Corp. and accepted the position of consulting physical chemist to the company.

A. V. H. Mory, recently director of the technical laboratories of Sears, Roebuck & Co., has resigned this connection to engage in executive duties as head of the chemical division of the Procter & Gamble Co., at Cincinnati. Mr. Mory was graduated from Ross Polytechnic Institute in 1894; was assistant chemist of Armour & Co. 1896-1901; in charge of the laboratory of Armour Packing Co., Kansas City, 1901-1907; chief of the U. S. Food and Drug Inspection Laboratory, Kansas City, 1907-1911. In 1911 he was invited by Sears, Roebuck & Co. to put into effect his ideas concerning the organization of a technical department, applying the spirit of the food and drug act to a general line of merchandise, including almost every article of commerce. His marked success in this work during the past nine years is well known to the members of the profession.

R. W. Mumford has accepted the position of chemical engineer in charge of development at the American Trona Corp. plant at Searles Lake, Cal.

E. C. Prins, chemical engineer of the University of Delft, Holland, is in the United States for the purpose of visiting industrial chemical plants.

Oliver C. Ralston of Colorado Springs, Col., has been appointed superintendent of the Seattle experiment station of the Bureau of Mines. Mr. Ralston is a chemist and an electrometallurgist. He was formerly connected with the Salt Lake City experiment station of the Bureau of Mines, but for the past two years has been engaged in electrochemical work at Niagara Falls for private interests.

Edward N. Roberts has resigned his lieutenancy in the Sanitary Corps and has accepted a position as assistant professor of chemistry at the University of West Virginia.

Dr. W. F. Straub, who was formerly with the Abbott Laboratories, has recently organized a chemical and biological laboratory with Dr. C. A. Zell, to be known as the Zell-Straub Laboratories, located at 1611 Masonic Temple, Chicago, Ill.

U. B. White, who has been connected with the administrative branch of the experiment station work of the Bureau of Mines, has resigned to become assistant secretary of the American Chemical Society. He will be attached to the office of Dr. Charles L. Parsons, in Washington.

Obituary

Richmond Levering, president of Richmond Levering & Co., Inc., promoters and developers of oil interests, died on Jan. 28, of pneumonia, in his thirty-ninth year, at his residence, 1 East 56th St., New York City.

Mr. Levering was graduated in 1902 from Sheffield Scientific School at Yale, where he rowed on the crew. Going to the Middle West, he became a pioneer in the development of the Illinois oil fields. His first large promotion was that of the Indian Oil Refining Co. Later he organized many oil properties in Texas and Mexico. Two of the leading concerns he promoted, both often in the public prints as a result of the enormous speculation of the period, were the Metropolitan Petroleum Corp. and the Island Oil & Transport Co.

During the war Mr. Levering was chief of the secret service division of the American Protective League in New York and special representative of the Department of Justice in Latin-American countries. With the rank of major he was chief engineer of the mechanical section of the American University Experiment Station in Washington. He was director of a half dozen oil companies.

Current Market Reports

The Non-Ferrous Metal Market

New York, Feb. 2, 1920.—The metal market was very firm last week. The only changes were in tin, zinc, silver and mercury.

	Cents per Lb.
Copper, electrolytic	19.50
Aluminum, 98 to 99 per cent	32 @ 33
Antimony, wholesale lots	11.00
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	60.12½
Lead, New York, spot	8.62½
Lead, E. St. Louis, spot	8.30
Zinc, spot, New York	9.40
Zinc, spot, E. St. Louis	9.05
Silver (Dollars per oz.)	1.34½

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	27.50
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00
Brazed brass tubing	37.00
Brazed bronze tubing	41.75
Seamless copper tubing	33.50
Seamless bronze tubing	34.50
Seamless brass tubing	30.50

RARER METALS*

Cadmium	lb.	$1.50 @ 2.50
Cobalt	lb.	1.90
Platinum	oz.	150.00
Iridium	oz.	250.00
Palladium	oz.	150.00
Mercury	75 lb.	85.00

SCRAP METALS

	Cents Per Lb.
Aluminum, cast scrap	23½ @ 24½
Aluminum, sheet scrap	22½ @ 23½
Aluminum clippings	25½ @ 27
Copper, heavy machinery comp.	14½ @ 14¾
Copper, heavy and wire	13¾ @ 14
Copper, light and bottoms	12½ @ 12¾
Copper, heavy cut and crucible	15½ @ 16
Brass, heavy	7½ @ 8½
Brass, casting	10½ @ 10¾
Brass, light	5¾ @ 6¾
No. 1 clean brass turnings	8¼ @ 8¾
No. 1 comp. turnings	12 @ 12½
Lead, tea	5½ @ 5¾
Lead, heavy	6½@ 7
Zinc, scrap	4½@ 4¾

The Iron and Steel Market

Pittsburgh, January 30, 1920.

The aspect of the steel market has changed radically in the past week. The recent prospect has now disappeared that the market would be stabilized by the independents definitely restraining the advancing tendency after Steel Corporation leadership, on the basis of March 21 or Industrial Board prices, had been renounced. Definite and precise action was necessary to avoid a runaway, and this action has not been taken. Prices quoted by the various independents show a wide variation and show no direct relation with either of the price schedules upon which the independent market might possibly have been stabilized, those two being the war control prices and the prices ruling from Dec. 12, 1918, when certain reductions were made, to the date of the Industrial Board reductions of March 21, 1919. It had become clear several weeks ago that the independents would not follow the Steel Corporation leadership. The corporation has not departed from its policy, and it has not only adhered to the March 21 prices but has sold rather heavily at those prices, necessarily to its regular customers only.

The Steel Corporation has now announced a general wage advance of 10 per cent, this percentage to apply to common labor, while other wage rates will be adjusted in keeping. The independents will necessarily follow. While price changes and wage rate changes are naturally supposed to have more or less relation with each other, it is of interest to note that while it is the independents that have been advancing prices, the Steel Corporation making no change, it is the Steel Corporation that takes the lead in advancing wages.

Not only are independent steel producers advancing prices, some of them remain practically out of the market, having definite sales that will carry them only until about April 1, while they have made some promises to regular customers to the effect that they will take care of their requirements in the second quarter, at prices to be named later, perhaps by March 1 or March 10. These conditions add to the nervousness of consumers, who are even more disposed to make bids to producers in hopes of securing protection. All the conditions are conducive to there being a runaway instead of a stabilized market.

Runaway in the Steel Market

It is reasonably clear, therefore, that a runaway in the steel market has actually begun. It is entirely a matter of doubt why the runaway is permitted and how long it will last. The independents may have wished that a runaway could be prevented, but felt powerless to hold the market, or they may have felt that the profits to be secured during a runaway would overbalance the obvious disadvantages involved. There has been only one complete runaway in the steel market's history, that of 1899, and thus there is no experience as to how long a runaway in steel may last. In 1917 a runaway started, but the expectation of the imposition of Government control dampened it long before the actual control was established. The runaway of 1899 lasted only a few months. Then there was no Steel Corporation, and it is possible that the independents feel now that whenever the ground covered by their sally becomes untenable they can retire to the Steel Corporation's line of defense. It may possibly be found that the farther the independents advance their prices above the March 21 schedule the more strongly, if possible, the Steel Corporation will be disposed to adhere to that schedule. Though without abandoning one iota of the policy adopted, the Steel Corporation is free to make moderate advances in its prices, in keeping with increases in production costs, and particularly the increase caused by the 10 per cent wage advance effective Feb. 1, which will increase costs on several millions of tons of steel sold at March 21 prices and still to be manufactured.

The argument need not be elaborated that there are no alternatives but a stabilized steel market and a runaway. Except from the long range view the market is not a matter of actual production and actual consumption, but one of demand and offerings. Even in a market that is safe against radical advances and with producers relatively free in selling, buyers become nervous and seek to purchase farther and farther ahead. Now there is no assurance of price advances being moderate, but rather the contrary prospect, and the independent producers are very reserved in the matter of selling, some having been almost out of the market for months. Consumptive requirements may exceed production, but apart from that the demand greatly exceeds the offerings, hence the only alternatives are a runaway and a stabilized market.

While the Steel Corporation has absolutely stabilized its own prices up to date by refraining from making any sales at above the March 21 schedule, the independents have done nothing to stabilize their market and the time when such a thing could be done has in all probability passed. There is no coherence between prices quoted by one independent and another, and the same producer frequently quotes different products at different levels, offering one product at the Jan. 1 price, another at the war control price and another at a price still higher. The theories recently propounded that the independents would by individual action adopt either the Jan. 1 price schedule or the war control schedule has been exploded by the prices they actually quote to prospective buyers, and at which they have made sales to regular customers of long standing.

Pig Iron Market Likewise in a Runaway

The pig iron market is likewise engaged in a runaway. It had the earmarks of a runaway in the rapid advances that occurred from about the beginning of October until the short holiday dullness intervened, but at that time there was the influence of steel prices, which were not advancing markedly, and thus the steel market might have held the pig iron market within some kind of bounds. That influence has now disappeared. Basic and foundry iron have advanced to $40, valley, and bessemer to $41, further advances being in clear prospect since the furnaces that are selling—second half delivery being about all that is available—profess to be selling some "backlog" business only. The Eastern market has advanced to $44.35, delivered Philadelphia, for No. 2X. While $50 pig iron is being predicted, that price is merely selected as a round figure for predicting purposes. It does not represent the buyers' limit any better than $45 or $55 would, since the buyers' limit is not known.

Some independent steel mills recently sold sheet bars to regular customers at $50, the March 21 price being $42, but will sell no more at that figure, and now ask $55 from regular customers, and about $60 from chance buyers.

Ferro-Alloys

Producers of ferromanganese continue to jump prices, and are said to be fully sold up for the first half, quotations now being $150 to $160, delivered, for 76 to 80 per cent. Spiegeleisen is quotable at $47.50 for spot and $50 to $55 for futures, at furnace.

Electrolytic ferrosilicon is quoted at $80 for 50 per cent and at $140 for 75 per cent, delivered Pittsburgh, valleys and Cleveland. Bessemer ferrosilicon is quoted still by some sellers at $59.50 for 10 per cent, $62.80 for 11 per cent and $66.10 for 12 per cent, but one or two producers are reported to have made advances and others may follow.

The Chemical Market

New York, February 2, 1920.

Firmness was the predominating note of last week's heavy chemical market. No drop has occurred in foreign inquiry, the alkalis receiving special attention. Spot material on any item is hard to find, the supply still remaining limited, which has sustained the present price level. Contract business with year-end delivery is being sought, as many producers are all sold up until that time.

Heavy Chemicals

Soda ash has been causing trouble, as it is practically off the market at present. The quotation of $2.25 per cwt. is nominal, as whatever material is on hand is being quoted at higher prices. Manufacturers are pressing their plants to the limit in order to meet contracts, and it is evident that it will be some time before this item recovers. *Bichromate of soda* is stronger and another jump is expected soon. Small lots are to be had on spot, but the 20@21c. quotation on contract prevails.

Epsom salts have increased in demand at a quotation $2.50@$2.70 per cwt., varying with the quantity. The association's price on *caustic soda* remains $4.25 per cwt., but it is unable to furnish any at this price. The average quotation is about $4.35 with no increased stocks in sight. *Formaldehyde* is stronger at 51@52c. per lb., with the entire output filling contracts. Even small quantities used by jobbers are practically exhausted. *Sal ammoniac* continues strong at 12¼@14c. per lb. and a rise in this item is due owing to an increased demand and decreased supply. The quotation on English material jumped 1c. to 11¼c., with the supply falling off. Exporting from England to this country is considerably less than it was a few months ago due to a shortage of ammonia liquor, and when these stocks are depleted a rise is expected on the domestic. *Chloroform* remains firm at 30@31c., most business being done on small lots. *Cream of tartar* has been active, but previous quotation of 56@60c. still holds. *Permanganate of potash* has been rather quiet, but owing to the scarcity of spot material the price still remains 65@75c. per lb. *Borax* continues under good demand with the same prices holding. The offerings on this item have fallen off slightly.

Coal-Tar Products

The extreme shortage in nearly all branches of this field has not become any easier. Large producers have withdrawn a number of items from this market and are reserving them for their own use. Expansion of plants has been going along steadily, but until there is some definite arrangement made whereby the American manufacturer will be protected from foreign markets, production will continue to fall short of demand, as the present facilities are not sufficient to meet the requirements. *Solvent naphtha*, water white, is to be had at 22@27c. per gal. The supply is fair, but inquiry has been light. *Benzol* is practically unattainable at present and there is no immediate relief in sight from this pressure. The reserve stocks, surplus after the war, of *toluol* are now being drawn upon and this branch has been easier, 28@29c. still holding.

Waxes

The waxes have been quiet, with the usual trading in small quantities and prices remaining at the same level. *Montan* is back on the market after an absence of several years and the present quotation is 30@31c. per lb. *Paraffines* remain unchanged in price with no relief in supplies. Buyers are not overanxious to stock up at the present prices, which accounts for this firmness.

Naval Stores

Spirits of turpentine is still active at $1.97 per gal., with a good supply of material in this market. The Savannah market has been advancing steadily and at present is quoted $1.88¼, while the London market remains unchanged, speculation is ripe and supply remains far behind the demand. All grades of the *rosins* continue firm, with F grade in a place of special importance, quoted at $19.75 per ton.

The much abused difficulty of rate of exchange is accountable for the quietness in the *crude rubber* market. Buyers are not out for spot, and on the other hand sellers seem averse to parting with stocks that were bought at a higher rate of exchange, but despite this condition the market has remained fairly steady, with a slight drop of ½c. on *para*, upriver fine, to 47c. per lb. and also plantation, ribbed smoked, sheets, came down to 50@51c. per lb., against 51¾ of last week.

Vegetable Oils

Buyers of *linseed oil* seem well stocked up, as very few sales have been reported. The current price is $1.77 per gal. carlot, $1.80 less than carlot. A price of $1.65 can be obtained on forward delivery of May or June. *Soya bean* remains firm, with little new business, Manchurian remaining firm at 19@23c. per lb.

Cincinnati, February 2, 1920.

The continued scarcity of all raw materials has created a very firm tendency to the market for chemicals in Cincinnati. The market in all lines is very strong and in some instances stocks are sold up to as far as April. No improvement in the situation is looked for until the new stocks arrive in the spring.

Chemical plants, in an effort to meet the heavy demand for their products and to catch up with orders which have been delayed because of various adverse circumstances, are working three shifts daily.

Only current prices are available, as the price changes are noted daily. Some changes in prices have been made within the past few weeks, but these have been only to the extent of a cent or two. Spot stocks are few. Many bids have been made, with very few offerings. The coal situation has now righted itself in this district to a great extent and no further discontinuance of operations because of a fuel shortage is looked for, at least for the remainder of the winter.

Heavy Chemicals:—The market for heavy chemicals is firm with the demand strong. *Sodium bichromate* is quoted at 18½c. in carload lots and is very scarce. The price on this particular item has not changed within the last month. Some offerings have been made at 35@37c., but none has changed hands at that price. *Ammonium chloride* rules firm, with gray at 12¾c. and white at 16½c. No change was noted in the prices of this article in the past two weeks. Solid *caustic soda* is firm at $4.75 per cwt. f.o.b. Cincinnati. *Tin* is still very scarce and is quoted at 60c., an increase of 1c. over the quotation two weeks ago.

Coal-Tar Products:—A rise of a cent or two has been made in some products, with the market ruling firm. No spot stocks are available and in some instances stocks are sold up to April 1. *Benzol* is quoted at 41c., against 40c. two weeks ago. *Aniline oil* is selling at 37c., against 36c. two weeks ago; *aniline salts* is quoted at 41c., an increase of 1c. over the price of two weeks ago; *nitrotoluol* at 18c., there having been no price change over the quotation two weeks ago; *orthonitrotoluol* was selling at 27c. two weeks ago and has been increased to 28c.; *salicylic acid*, quoted at 92c., was quoted two weeks ago at 90c. *Benzoic acid* increased from $1.50 two weeks ago to $1.55.

Vegetable Oils:—The market for vegetable oils is very strong with no spot stocks. *Cotton oil* crude for February shipments did not increase, the quotation at 21¾c. two weeks ago ruling at this time. *Corn oil* continues active, with no price change at 21½c. in bbl. lots. *Menhaden fish oil* jumped 5c. on a gal., from $1.20 to $1.25. *Soya bean oil* in sellers' tanks is selling at 17¾c., against 17½@18c., with the demand strong. *Manila cocoanut oil* in sellers' tanks jumped to 19½@20c., against 18¾c., the price of two weeks ago. No price change was made in *linseed oil*, the present quotation being $1.79 in less than 5-bbl. lots.

Naval Stores:—The market is very firm. *Turpentine* in single barrels jumped to $2.03 over the price of $1.74. The market is very strong on this particular item, with no spot stocks, the supply being sold up to April. The market for *rosin* is very strong, with the prices on the increase, the latest quotation on F grade being $19, against $17.75 two weeks ago. *Raw white* is the same, at $22.35.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0.60 – $0.65
Acetone	lb.	$0.16 –$0.20	.21 –
Acid, acetic, 28 per cent	cwt.	2.50 – 3.00	3.00 – 3.25

Litharge	lb.	—	.09½– .10½
Lithium carbonate	lb.	—	1.50 –
Magnesium carbonate, technical	lb.	—	.13 – .14½
Magnesium sulphate, U. S. P.	100 lb.	2.15 – 2.63	2.75 – 3.00
Magnesium sulphate, commercial	100 lb.	1.75 –	2.00 – 2.50
Nickel salt, double	lb.	.14 –	.15 –
Nickel salt, single	lb.	.12 –	.15 – .16
Phosgene (see carbonyl chloride)		—	—
Phosphorus, red	lb.	—	.75 – .90
Phosphorus, yellow	lb.	—	.35 – .37
Potassium bichromate	lb.	.28 – .33	.34 – .35
Potassium bitartrate (cream of Tartar)	lb.	—	.56 – .60
Potassium bromide, granular	lb.	—	.50 – .65
Potassium carbonate, U. S. P.	lb.	.60 –	.65 – .70
Potassium carbonate, crude	lb.	.26 – .27	.28 – .30
Potassium chlorate, crystals	lb.	.16 – .20	.21 –
Potassium cyanide, 98-99 per cent	lb.	nominal	
Potassium hydroxide (caustic potash)	lb.	.23 – .32	.35 – .42
Potassium iodide	lb.	—	3.35 – 3.60
Potassium nitrate	lb.	.19 –	.21 –
Potassium permanganate	lb.	—	.65 – .95
Potassium prussiate, red	lb.	—	1.10 – 1.20
Potassium prussiate, yellow	lb.	—	$0.40 – $0.70
Potassium sulphate	ton	$225.00 –	—
Rochelle salt (see sodium potas. tartrate)		—	—
Sal ammoniac (see ammonium chloride)		—	—
Sal soda (see sodium carbonate)		—	—
Salt cake (sodium sulphate)	ton	18.00 –21.00	—
Silver cyanide	oz.	—	1.25 –
Silver nitrate	oz.	—	.81½– .82½
Soda ash, light	100 lb.	2.05 –	2.25 –
Soda ash, dense	100 lb.	2.25 – 2.35	2.50 – 2.75
Sodium acetate	lb.	.06¾– .07	.07 – .08
Sodium bicarbonate	100 lb.	2.40 –	2.75 – 3.00
Sodium bichromate	lb.	.20 – .21	.22 – .25
Sodium bisulphate (nitre cake)	ton	6.00 – 8.00	10.00 –
Sodium bisulphite	cwt.	1.80 – 1.90	2.00 – 2.10
Sodium borate (borax)	lb.	— .08	.08½– .09
Sodium carbonate (sal soda)	100 lb.	1.40 – 1.55	1.50 – 1.75
Sodium chlorate	lb.	.10 –	.12 – .14
Sodium cyanide, 96-98 per cent	lb.	.30 –	.31 – .34
Sodium fluoride	lb.	.14 –	.15 – .16
Sodium hydroxide (caustic soda)	100 lb.	—	4.35 – 4.50
Sodium hyposulphite	lb.	—	.03¾– .04
Sodium molybdate	lb.	2.50 –	3.25 –
Sodium nitrate	100 lb.	3.00 – 3.25	3.75 – 4.00
Sodium nitrite	lb.	.15 – .17	— .18
Sodium peroxide, powdered	lb.	—	.30 – .32
Sodium phosphate, dibasic	lb.	.03¾– .04¼	.04¼– .05
Sodium potassium tartrate (Rochelle salt)	lb.	.40 – .42	.43 – .45½
Sodium prussiate, yellow	lb.	.23 – .39	.24 – .40
Sodium silicate, solution (40 deg.)	lb.	.01¼– .02	.02 – .02½
Sodium silicate, solution (60 deg.)	lb.	.02½– .03	.03½– .04½
Sodium sulphate, crystals (Glauber'ssalts)	cwt.	1.30 – 1.50	1.60 – 2.00
Sodium sulphide, crystal, 60-62 per cent. (conc.)	lb.	—	.05 – .06
Sodium sulphite, crystals	lb.	.03½–	.04 – .06
Strontium nitrate, crystals	lb.	.25 –	.28 –
Sulphur chloride	lb.	.05¼–	.06 –
Sulphur, crude	ton	22.00 –	—
Sulphur dioxide, liquid, cylinders	lb.	.09 –	.10 – .12
Sulphur (sublimed), flour	100 lb.	3.35 –	3.40 – 3.65
Sulphur, roll (brimstone)	100 lb.	3.20 –	3.30 – 3.40
Tin bichloride (stannous)	lb.	.42½–	.46 – .50
Tin oxide	lb.	.43 –	.60 –
Zinc carbonate, precipitate	lb.	—	.20 –
Zinc chloride, gran	lb.	.12¼–	.13½– .15
Zinc cyanide	lb.	.49 –	.50 –
Zinc dust	lb.	.11¼– .12½	.13 – .15
Zinc oxide, dry American	lb.	—	.09½– .12
Zinc sulphate	lb.	.03½– .03¾	.04 – .04½

*Nominal quotations.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.34 —	.36
Aniline oil, drums extra	lb.	.34 —	.36
Aniline salts	lb.	.45 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.25 —	1.30
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.52
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U.S.P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.75 —	.80
Cresylic acid, 95-97%, dark, in drums	gal.	.72 —	.75
Cresylic acid, 50%, first quality, drums	gal.	.60 —	—
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline	lb.	.90 —	1.00
Dinitrobenzol	lb.	.26 —	.37
Dinitroclorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.58 —	.75
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.27 —	.30
Ortho-amidophenol	lb.	3.00 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.90 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.15 —	.18
Paranitraniline	lb.	1.00 —	1.20
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.50 —	4.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.60 —	1.00
Phenol, U.S.P., drums (dest.), (240 lb.)	lb.	.12¾ —	.19
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.55 —	.60
Salicylic acid, U.S.P.	lb.	.42 —	.50
Salol	lb.	.90 —	.95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.22 —	.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30

Toluidine	lb.	$1.70 —	$2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.45
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white, pure	lb.	.63 —	.68
Carnauba, No. 1	lb.	.80 —	.88
Carnauba, No. 2, regular	lb.	.65 —	.78
Carnauba, No. 3, North Country	lb.	.46 —	.48
Japan	lb.	.18½ —	.20
Paraffine waxes, crude match wax(white) 105-110 m.p.	lb.	.06 —	.07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.... —	.07
Paraffine waxes, refined, 118-120 m.p.	lb.	.... —	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½ —	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	.... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	.... —	.14
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist.	gal.	....
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp.gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref.	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots:

Rosin B-D, bbl.	280 lb.	$17.00 —	$17.50
Rosin E-I	280 lb.	17.85 —	18.40
Rosin K-N	280 lb.	19.75 —	22.50
Rosin W. G.-W. W.	280 lb.	22.50 —	24.25
Wood rosin, bbl.	280 lb.	17.00 —	17.50
Spirits of turpentine	gal.	.... —	1.97
Wood turpentine, steam dist.	gal.	.... —	1.70
Wood turpentine, dest. dist.	gal.	1.64 —	....
Pine tar pitch, bbl.	200 lb.	8.25 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	14.75
Retort tar, bbl (500 lb.)	bbl.	15.00 —	15.25
Rosin oil, first run	gal.	.... —	.91
Rosin oil, second run	gal.	.93 —	.94
Rosin oil, third run	gal.	1.10 —	1.12
Rosin oil, fourth run	gal.	.... —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V.M. and P. naptha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.47 —	$0.48½
Upriver coarse	lb.	.34 —	.35
Upriver caucho ball	lb.	.33½ —	.34½
Plantation—First latex crepe	lb.	.52 —	.54½
Ribbed smoked sheets	lb.	.50 —	.51
Brown crepe, thin, clean	lb.	.48	.48½
Amber crepe No. 1	lb.	.53 —	....

Oils

VEGETABLE

The following prices are f.o.b., New York, for carload lots:

Castor oil, No. 3, in bbls	lb.	$0.18 —	$0.19
Castor oil, AA, in bbls	lb.	.21 —	.23
China wood oil, in bbls	lb.	.23½ —	.24½
Cocoanut oil, Ceylon grade, in bbls	lb.	.21 —	.21½
Cocoanut oil, Cochin grade, in bbls	lb.	.20½ —	.23
Corn oil, crude, in bbls	lb.	.19 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19 —	.20
Cottonseed oil, summer yellow	lb.	.22 —	.27
Cottonseed oil, winter yellow	lb.	.24½ —	.25½
Linseed oil, raw, car lots	gal.	1.77 —	1.87
Linseed oil, raw, tank cars	gal.	1.70 —	1.80
Linseed oil, boiled, car lots	gal.	1.75 —	1.80
Olive oil, commercial	gal.	2.50 —	2.60
Palm, Lagos	lb.	.17 —	.18
Palm, bright red	lb.	.16½ —	.17½
Palm, Niger	lb.	.16 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½ —	.24
Peanut oil, refined, in bbls	lb.	.27 —	.28
Rapeseed oil, refined in bbls	gal.	1.45 —	1.68
Rapeseed oil, blown, in bbls	gal.	1.60 —	1.70
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.19 —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17½ —	.20

FISH

Winter pressed Menhaden	gal.	$1.20 —	....
Yellow bleached Menhaden	gal.	1.23 —	....
White bleached Menhaden	gal.	1.25 —	....
Blown Menhaden	gal.	1.26 —	....

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$35.00 —	$40.00
Barytes, off color	ton	20.00 —	25.00
Blanc fixe, dry	lb.	.03½ —	.04½
Blanc fixe, pulp	ton	30.00 —	50.00
Casein	lb.	.16 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	$ .04½ —	$ .06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	25.00 —	35.00
China clay (Kaolin), imported, powdered	ton	30.00 —	60.00
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	13.50 —	18.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30.00 —	35.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35.00 —	45.00
Fuller's earth, domestic, powdered	ton	25.00 —	30.00
Fuller's earth, imported, powdered	ton	35.00 —	40.00
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	....
Shellac, TN	lb.	1.10 —	1.15
Shellac, D. C.	lb.	.... —	....
Shellac, V. S. O.	lb.	.... —	....
Shellac, Diamond I.	lb.	.... —	....
Shellac, orange, fine	lb.	1.25 —	....
Shellac, orange, superfine	lb.	1.20 —	1.30
Shellac, A. C. garnet	lb.	1.10 —	....
Shellac, bleached, bone dry	lb.	1.35 —	....
Shellac, bleached, fresh ground	lb.	1.10 —	1.15
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	60.00 —	70.00

Refractories

Following prices are f.o.b. works:

Chrome brick	net ton	$75-80 at Chester, Penn.
Chrome cement	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay	1,000	38-45 at Clearfield, Penn.
Clay brick, 2nd quality	1,000	33-35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80-85 at Chester, Penn.
Silica brick	1,000	45-50 at Mt. Union, Penn.

Ferro-Alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$250.00
Ferro-chrome per lb. of Cr contained, 6-8% carbon	lb.	.20 —	.40
Ferro-chrome per lb. of Cr contained, 2-4% carbon	lb.	.21 —	.50
Ferro-manganese, 70-80% Mn	gross ton	140.00 —	155.00
Spiegeleisen, 16-20% Mn	gross ton	40.00 —	50.00
Ferro-molybdenum, per lb. of Mo	lb.	3.00 —	3.50
Ferro-silicon, 50%	gross ton	85.00 —	95.00
Ferro-silicon, 75%	gross ton	150.00 —	175.00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.	lb.	1.25 —	1.40
Ferro-uranium, 35-50%, of U	lb.	7.00 —	....
Ferro-vanadium, 30-40% per lb. of contained V.	lb.	5.50 —	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.60 —	$0.85
Chrome ore, 48% and over	unit	1.00 —	1.25
*Coke, foundry, f.o.b. ovens	net ton	7.00 —	7.50
*Coke, furnace, f.o.b. ovens	net ton	6.00 —	6.50
Petroleum coke, refinery, Atlantic seaboard	net ton	.... —	14.00
Fluorspar, gravel, f.o.b. mines	net ton	.... —	25.00
Manganese ore, 45% Mn and over	unit	.50 —	.75
Manganese ore, chemical (MnO_2)	gross ton	60.00 —	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over, per unit of WO_3	unit	9.00 —	15.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	7.50 —	10.00
Uranium oxide, 96%	lb.	2.75 —	3.00
Vanadium pentoxide, 99%	lb.	6.00 —	....
Pyrites, foreign, lump	unit	.17 —	....
Pyrites, foreign, fine	unit	.17 —	....
Pyrites, domestic, fine	unit	.16 —	.17½
Ilmenite, 52% TiO_2	lb.	.02 —	....
Rutile, 95% TiO_2	lb.	.11 —	....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	2.75 —	3.00
Zircon, washed, iron free	lb.	.10 —	....
Monazite, per unit of ThO_2	unit	42.00 —	....

* Government prices.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags, delivered	bbl.	$2.80
Lump lime, common, including container, at plant	300 bbl.	2.75
Common brick, delivered	M.	25.00
Yellow pine, 3x4 to 8x8, 20 ft. and under	M.	58.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at Chicago	M.	70.00
Yellow pine, 3x4 to 8x8, 20 ft. and under at St. Louis	M.	44.00
Roofings, tar felt (14 lb. per 100 sq. ft.)	ton	84.00
Roofings, tar pitch (in 400-lb. bbl.) carlots	ton	21.00
Roofings, asphalt pitch carlots	ton	34.00
Roofings, asphalt felt carlots	ton	88.00
Roofings, slate-surfaced, per roll of 108 sq. ft. carlots		3.00
Roofings, slate-finished shingles, 100 sq. ft. carlots		7.25
Linseed oil, raw in barrels	gal.	1.80
Linseed oil, 5 gal. cans	gal.	2.00
Red lead, dry, 100 lb. keg	lb.	.14½
Red lead, in oil, 100 lb. keg	lb.	.16
Red lead, dry, 5 lb. cans	lb.	.16½
Red lead, in oil, 5 lb. cans	lb.	.17
White lead, dry and in oil, 100 lb. keg	lb.	.14½
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.14½
White lead, dry and in oil ,5 lb. cans	lb.	.16½

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Ridgeway Paper Stock Co., 1619 Ave. E., plans to construct a 100x250-ft. paper mill with a daily capacity of 50 tons. Estimated cost, $250,000. B. G. Ridgeway, pres.

California

PASADENA—The Throop College of Technology plans to build a physical laboratory building in connection with College on East California St. Estimated cost, $150,000. Bertram G. Goodhue, 2 West 47th St., New York City, archt.

Connecticut

WESTPORT—The Dolge Chemical Co. has awarded the contract for the construction of a 1-story factory, to Barney-Ahlers Constr. Co., 110 West 40th St., New York City. Estimated cost, $40,000.

Illinois

CHICAGO—Schmidt, Garden & Martin, archts., 104 South Michigan Ave., will soon award the contract for the construction of a 2-story, 50x250-ft. addition to the plant of the Chicago Solder Co., 218 North Union Ave. Estimated cost, $100,000.

Iowa

DES MOINES—The Hawkeye Tire & Rubber Co., 215 East 3rd St., has awarded the contract for the construction of a 3-story, 80x280-ft. factory, to John M. Benson, 422 V. M. B. Bldg. Estimated cost, $300,000.

Kansas

ELGIN—The North Amer. Refining Co. plans to build an oil refinery to refine the high-grade crude oil produced here. Estimated cost, $350,000.

Maryland

BALTIMORE—The Locke Insulator Co., Victor, N. Y., is having plans prepared for the construction of two buildings and twenty-four kilns for the manufacture of porcelain insulators, on Light St. and Ferry Bar, here. Estimated cost, $1,000,000.

CURTIS BAY (Baltimore P. O.)—The Kennedy Corp., Charles and Wells Sts., plans to build a plant here. Four open-hearth melting furnaces fired by fuel oil and seven annealing furnaces using powdered coal will be installed in same. J. P. Kennedy, pres. Noted Sept. 30.

Michigan

DETROIT—The Amer. Electrical Heater Co., Woodward and Burroughs Sts., has awarded the contract for the construction of a 1-story, 60x417-ft. factory and boiler house addition and a 23x32-ft. assembling room for electrical heating devices, on Commer and Dequindre Sts., to Conrad Keller, 210 Moran St., at $35,000.

New Jersey

EDGEWATER—The Barrett Co., 17 Battery Pl., New York City, has awarded the contract for the construction of a 2-story, 25x73-ft. laboratory building, here, with el 27x50 ft., to the Turner Constr. Co., 244 Madison Ave., New York City.

HOBOKEN—J. C. Schaeffler, archt. and engr., 40 West 32nd St., New York City, will receive bids about Feb. 16, for the construction of a 6-story, 135x135-ft. factory and a 3-story, 20x80-ft. foundry, for the White Metal Mfg. Co., 1006 Clinton St.

NEWARK—The Celluloid Co., 290 Ferry St., has awarded the contract for the construction of a 3-story, 40x50-ft. factory addition on Charles St., to Eustice Bros., 40 Clinton St.

TRENTON—The Union Electrical Porcelain Co., Hamilton and Clark Sts., plans to build a large porcelain manufacturing plant to replace the one recently destroyed by fire with a loss of $90,000. T. A. McKenzie, 1404 Greenwood Ave., pres.

New York

BALDWINSVILLE—The Morris Machine Wks. are in the market for a large oil-burning brass furnace. Address, L. L. Hofmann, secy. and treas.

CLAYTON—The Toggarts Paper Co., Sherman Bldg., Watertown, has purchased a 100-acre site at Steeles Point along the waterfront of the St. Lawrence River and adjacent to the New York Central R.R., and plans to construct a wood-preparing plant, etc., on same. Estimated cost, $100,000.

NEW YORK—J. M. Felson, archt. and engr., 1133 Bway., will soon award the contract for the construction of a 25x100-ft. factory addition at 12 West End Ave., for the Natl. Gum & Mica Co.

RYE—The city rejected all bids for the construction of sanitary sewers and sewage disposal units, involving 31,100 ft. of 8-in. and 580 ft. of 15-in. vitr. pipe sewers, etc. Estimated cost, $300,000. G. E. Hill, 45 7th Ave., New York City, engr. Work will be readvertised.

UTICA—The Utica Cutlery Co., 820 Hickory St., has awarded the contract for the construction of a 3-story, 55x200-ft. addition to its plant at Hickory St. and Wheeler Ave., to Griffith & Pierce, 618 Charlotte St. Estimated cost, $125,000.

Ohio

CLEVELAND—The Regar Brass Co., 1523 East 45th St., has awarded the contract for the construction of a 1-story, 24x42-ft. furnace building at East 45th St. and Superior Ave., to the Du Perow Constr. Co., Plymouth Bldg. Estimated cost, $7,000.

DAYTON—The Dayton Rubber Mfg. Co., West River St., plans to construct a 1-story, 70x200-ft. rubber manufacturing plant. Estimated cost, $35,000.

ST. BERNARD (Cincinnati P. O.)—The Jarecki Chemical Co. has awarded the contract for the construction of a 2-story, 150x500-ft. factory, here to the Austin Constr. Co., 16112 Euclid Ave., Cleveland. Estimated cost, $500,000.

WILLOUGHBY—The Thor Tire & Rubber Co., 802 Society for Savings Bldg., Cleveland, plans to construct a 1- and 2-story, 82x180-ft. rubber factory, on Main St. and New York Central R.R. Estimated cost, $150,000.

Oklahoma

FREDERICK—The Frederick Oil & Refining Co. has awarded the contract for the construction of a refinery, to A. H. Kruse. Estimated cost, $100,000.

MADILL—The city plans to improve the water-works, including the construction of a filtration plant, etc. Bonds for $410,000 were voted for this project. Johnson & Benham, Firestone Bldg., Kansas City, Mo., consult. engrs.

PAWHUSKA—The Osage Mutual Oil & Refining Co. plans to build an oil refinery, with a daily capacity of 1,500 bbl., on the Prairie along the Midland Valley Track. Estimated cost, $200,000.

Oregon

PORTLAND—The Oregon Brass Wks., 73 North 2nd St., have awarded the contract for furnishing and installing one 2,000-lb. capacity, and one 100-ton capacity electric steel furnaces, to the Detroit Electric Steel Furnace Co., 698 Hart St., Detroit, Mich. Estimated cost, $20,000.

PORTLAND—The Palmolive Co. plans to rebuild the 2-story, 100-ton capacity, copra mill which was recently destroyed by fire, and will install machinery for copra reduction and oil extraction in same. Estimated cost, $30,000.

Pennsylvania

JOHNSTOWN—The Lee-Strauss Co., formerly the Johnstown Chemical Co., 232 Levergood St., will soon receive bids for a 3- or 4-story, 55x100-ft. chemical plant and office building on Levergood St. Estimated cost, $150,000. Henry M. Rodgers, Trust Bldg., archt.

Rhode Island

WOONSOCKET—The Woonsocket Rubber Co., 87 Fairmount St., has awarded the contract for the construction of a 1-story, 40x50-ft. factory addition on Fairmount St., to the Fiske-Carter Constr. Co., 11 Foster St., Worcester, Mass. Estimated cost, $15,000.

Texas

STEPHENSVILLE—The A1-Tex Refining & Holding Co. has purchased a 20-acre site just outside of the city limits and plans to build a 2,500-bbl. capacity oil refinery on same. Estimated cost, $400,000.

Virginia

ROANOKE—The Bd. Educ. is having plans prepared for the construction of a 3-story school on Park St. A chemical laboratory will be installed in same. Estimated cost, $450,000. H. C. Richards, 1713 Sansom St., Philadelphia, archt.

Wisconsin

MILWAUKEE—The Pelton Steel Co., 672 Kinnickinnic Ave., is receiving bids for the constructon of a 1-story, 60 x 100-ft. foundry addition. Estimated cost, $35,000. Judell & Bogner, 1st Wisconsin Natl. Bank Bldg., archts. and engrs.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention in St. Louis, May 10 and 11.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23 to 26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will have a joint meeting with the American Chemical Society and the Society of Chemical Industry, Feb. 6, 1920. On Feb. 27 another meeting will be held, the subject for which is "Electric Furnace Reducing Agents." Another meeting will be held on March 26, the subject of which is Peace Uses for War Products.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16 to 19.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE FARADAY SOCIETY (London) will hold a joint meeting, March 1, with the London Section of the Society of Chemical Industry to receive and discuss a report of Dr. T. Martin Lowry, and E. C. Hemmings on the "Setting of Salts and Other Crystalline Substances." Another meeting will be held March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE INSTITUTE OF METALS will hold its annual general meeting March 11 and 12 at the Institution of Mechanical Engineers, Storey's Gate, Westminister, S. W. 1, London, England.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MATERIAL HANDLING MACHINERY MANUFACTURERS' ASSOCIATION will hold its convention at the Waldorf-Astoria Hotel, New York City, Feb. 26 and 27.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Industrial Notes

THE SULLIVAN MACHINERY CO. announces the appointment of Arthur E. Blackwood, hitherto manager of its branch office in New York City, as vice-president, in charge of finance and accounting, with headquarters at Chicago. Louis R. Chadwick, for a number of years manager of the company's office at Spokane, Wash., has been appointed manager at New York City, 30 Church St., succeeding Mr. Blackwood.

THE NEW JERSEY ZINC CO. announces the contemplated construction of additional zinc oxide and lithopone plants to meet the growing demand for these products. The company plans to construct its plants at strategic geographical points so as best to serve its customers located in various parts of the country. Construction work will be commenced immediately on zinc oxide and lithopone plants in Colorado and Pennsylvania.

THE ALLIED MACHINERY CO. OF AMERICA recently opened at Center and Walker Sts., New York City, a permanent exhibit of the products of fifteen non-competing manufacturers. This allied machinery center occupies 30,000 sq.ft. of space and is designed to serve the need of both export buyer and domestic purchaser who may be interested in general construction machinery.

THE ASSOCIATED WELDING COS., INC., Brooklyn, N. Y., is the title of a new organization which has recently consolidated thirteen welding companies operating in different parts of the country. As a holding company it operates and manages a chain of welding service companies, each of which is conducted as a separate unit with its own organization of engineers. An illustrated pamphlet entitled "Electric Arc Welding" has just been issued by the company.

MARDEN, ORTH & HASTINGS, New York City, announces that its sales department of coal-tar intermediates has been separated from the main company and incorporated under the firm name of Calco Chemical Co. No change in the personnel has taken place and the new company will continue to occupy the same quarters.

THE BLAW-KNOX CO., Pittsburgh, announces that A. W. Ransom, formerly manager of the New England territory, with offices at Boston, Mass., has been transferred to San Francisco in the capacity of manager of the Pacific Coast territory, with offices in the Monadnock Bldg. O. A. Olstad, formerly with the New York office, has been made manager of the New England territory, with offices in the Little Bldg., Boston, Mass., succeeding A. W. Ransom.

THE FULLER ENGINEERING CO., Allentown, Pa., has entered into contract with the Trumbull Steel Co., Warren, Ohio, to remodel the pulverized coal plant of the latter. The new equipment will comprise two 57-in. dreadnaught gear-driven mills and a 5½-ft. x 42-ft. indirect-fired drier. The pulverized coal from the Fuller mills will be transported by the Fuller-Kinyon pumping system to the bins at the furnaces. Motor-driven screw feeders attached at the bottom of the bins will mix the coal dust and the air for injection into the furnaces.

THE UNITED STATES CAST IRON PIPE & FOUNDRY CO. announces the opening of an office in the Scollard Bldg., Dallas, Tex., in charge of T. W. Hanlon, Southwestern sales agent.

THE UNITED SMELTING & ALUMINUM CO., INC., of New Haven, Conn., announces the election of Frederick A. Merliss as vice-president and manager of sales. Mr. Merliss has been connected with the company for the past three years as assistant secretary, and his new appointment fills the place left vacant through the resignation of L. M. Brile, former vice-president and sales manager.

THE GENERAL CHEMICAL CO. has entered into a contract with the J. G. White Engineering Corp. covering the future designing, engineering and construction work incident to improvements and extensions to existing manufacturing plants, buildings, and other property, and in connection with any new projects or developments which may be undertaken from time to time. Two initial pieces of work, which are to be carried out immediately under the new arrangement, are the construction of a large warehouse at Pittsburgh, and improvements to the company's Delaware works near Marcus Hook, Pa.

THE QUIGLEY FURNACE SPECIALTIES CO., New York City, has been awarded a contract by the Inland Steel Co., Indiana Harbor, for the engineering work and installation of a complete milling plant of twenty tons hourly capacity with provision for extensions, compressed air distribution system for transporting pulverized fuel to furnace bins through small diameter standard wrought pipes, and the necessary fuel feed controllers, air supply system and burners. For the initial installation, powdered coal will be applied to sixteen sheet furnaces, sixteen pair furnaces, three continuous plate-mill furnaces, two continuous bar-mill furnaces and three slab-heating furnaces. Arrangements are also being made for an extension to the boiler plant and other departments.

THE ALUMINUM CASTINGS CO., Cleveland, Ohio, announces the change of its name to Aluminum Manufacturers, Inc.

THE CLINTON-WRIGHT WIRE CO. has acquired the Wickshire Steel Co., and the combination will be known as the Wickshire-Spencer Steel Corp.

K. TEKN. HOGSKOLANS MATERIALPROVNINGSANSTALT announces that from Jan. 1, 1920, it has been organized as a state institution of Stockholm, Sweden, under the name of Statens Provningsanstalt.

GANNET, SEELYE & FLEMING, consulting engineers, of Harrisburg, Pa., have established Southern headquarters in Randolph Bldg., Memphis, Tenn.

THE PERFECT PRODUCTS CO. is establishing a manufacturing plant at 674 South Main St., Memphis, Tenn., for the production of automobile and furniture polish, automobile top and fabric dressing and shellac.

THE BAKER LABORATORIES, of Dallas, Tex., have established a manufacturing plant at 166 North Front St., Memphis, Tenn. This company manufactures toilet goods and dye products for all classes of leather. George W. Baker is president and W. K. Baker secretary.

THE COMBUSTION ENGINEERING CORP., New York City, has enlarged its facilities for handling business in the Philadelphia territory. The office of the company in this territory is located in the Lincoln Bldg., and W. C. Stripe, formerly of its Pittsburgh office, becomes manager. Associated with him on the selling force are C. L. Bachman, recently returned from military service abroad, and formerly manager of the Chicago office of this company, and E. F. Knehnle, formerly in the New York City office.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., is now devoting more floor space to the industrial electric heating department, which includes electric space heaters, soldering irons, linotype pot heaters, metal melting pots, immersion water heaters, circulation water heaters, etc.

JOSEPH T. RYERSON & SON, Chicago, and the CONRADSON TOOL MACHINE CO., Greenway, Wis., have recently formed an association for the sale of machine tools which will be marketed under the trade name of "Ryerson-Conradson."

THE QUIGLEY SYSTEM of preparing and burning powdered coal has been selected by the Philadelphia Rapid Transit Co. for its Mt. Vernon St. power station. This plant at present requires twenty 375-hp. Babcock & Wilcox water tube boilers, but with powdered coal firing the necessary power will be secured by using only ten boilers. By means of compressed air, pulverized coal will be transported through small diameter wrought pipes from an adjacent milling plant to the present coal bunker, which will be partitioned into ten sections, each section supplying coal individually to its corresponding boiler. The fuel is not mixed with air in transport, but travels through the pipes in compact masses. The equipment from milling plant to burners is entirely enclosed and dust tight. The change from hand fired to powdered coal will be made without interruption of service; and the new installation will be completed during the coming summer.

THE HIRSCH LABORATORIES, INC., is the name under which Dr. Alcan Hirsch has incorporated his laboratory. The company's office is in the Chemists' Bldg., 50 East 41st St., New York City, where it has been for the past eight years, but the laboratories and experimental plant have been removed to 593 Irving Ave., Brooklyn, N. Y. The officers of the new corporation are: Alcan Hirsch, president; Marx Hirsch, vice-president, and Harry W. Wolff, general manager.

HERVEY J. SKINNER, formerly of A. D. Little, Inc., announces the opening of an office in the Garden Bldg., 248 Boylston St., Boston, Mass., as a consulting chemical engineer. Particular attention will be paid to pulp and paper problems and the development of processes and their commercial application.

THE NATIONAL FOREIGN TRADE COUNCIL, India House, Hanover Sq., New York City, has published a pamphlet of interest to those engaged in export business. It defines the meaning of export quotations and the responsibility falling upon the seller and the buyer in each case and it also contains some general recommendations for the standard American export practice.

THE BIRMINGHAM COKE & BYPRODUCT CO., Birmingham, Ala., has completed its byproduct coke plant which was started under the direction of the Ordnance Department during the war. Work began in September, 1918, but on the signing of the armistice in November all work was discontinued. Work was again begun by the War Department April 1, 1919, and the plant is to be taken over April 1, 1920, by the Birmingham Coke & Byproduct Co. The plant has now a daily capacity of 825 tons of coke, 400 gal. of toluol and 11¼ tons of ammonium sulphate.

THE YARNALL-WARING CO., Philadelphia, Pa., has opened a branch office in the Builders' and Traders' Exchange, Penobscot Bldg., Detroit, in charge of Walter G. Heacock, as branch manager.

Manufacturers' Catalogs

THE BAUSCH & LOMB OPTICAL CO., Rochester, N. Y., has issued a booklet entitled "What Lens Shall I Buy?" This booklet is intended to furnish information which will assist the purchaser in the proper selection of a photographic lens.

HOLZ & CO., INC., New York City, has issued a leaflet describing the Holz universal photomicrographic and macrographic metallographic bench model 1920.

THE PENNSYLVANIA SALT MFG. CO., Philadelphia, is distributing a booklet listing its heavy chemicals.

THE WESTINGHOUSE ELECTRIC & MFG. CO., East Pittsburgh, Pa., has published a 50-page illustrated bulletin on the application of electricity to the metallurgical and chemical industries. Among the subjects treated at considerable length are the use of electric furnaces in ferrous and nonferrous metallurgy, industrial heating and the manufacture of such materials as carbide, electrolytic processes for the fixation of nitrogen and the precipitation of suspended matter in gases. The catalog contains information that will be suggestive of a variety of applications of electricity.

WESTINGHOUSE, CHURCH, KERR & CO., INC., New York City, has issued a folder entitled "Shops." It gives actual illustrations of industrial plants and describes what a shop is.

THE NELSON VALVE CO., Philadelphia, Pa., announces a new book just received from the press, entitled "Nelson Valves." This 156-page book illustrates and describes the many different types, which include bronze, iron and steel valves in gate, globe, check and non-return patterns, in fact, a type for every class of service found in power plant work, industrial establishments and large building construction.

THE WORTHINGTON PUMP & MACHINERY CORP., New York City, has issued an attractive 116-page book on "Condensing Apparatus," which is well illustrated and described. There are four sections, which include: surface condensers, with auxiliaries and pumping equipment; high vacuum surface condensers and equipment; jet and barometric condensers; useful information, condensation. This book also contains useful tables, notes and general information.

THE TECHNICAL PRODUCTS CO., INC., 501 Fifth Ave., New York City, calls attention to a catalog entitled "The Economist," in which are listed the surplus and idle equipment recently purchased at various plants. The material includes equipment of every sort used in the chemical and allied industries and is ready for immediate shipment.

THE KOPPERS CO., Pittsburgh, Pa., is issuing a 68-page bulletin on byproduct coke and gas oven plants, benzol recovery plants, motor fuel recovery plants, tar distilling plant, and ammonia recovery apparatus which it has designed and built. Many illustrations of actual installations are given, together with descriptive matter.

The Report of the British Nitrogen Products Committee

ONE of the revelations of the World War was the unpreparedness of the allied nations in the matter of nitrogen fixation. Not only did the beginning of the war find the principal English-speaking nations without a nitrogen-fixation industry and depending on Chile for sodium nitrate, but the war ended before either Great Britain or the United States had brought to completion their plans for the production of synthetic nitrates on a large scale. Germany alone developed her Haber process from insignificant proportions at the beginning of the war to an industry of great magnitude before hostilities ceased. True, with Germany it was a more vital matter than with the Allies, as the latter could still obtain some supplies of Chilean nitrate. In order to augment this supply Great Britain had, before the end of the war, considered the establishment on a large scale of the calcium cyanamide process, and on a development scale of the synthetic ammonia and ammonia oxidation processes. The United States had practically completed a similar program.

With the end of the war developments ceased abruptly and neither Great Britain nor the United States has made more than nominal progress since that time. As a consequence the plans of either nation are of the greatest importance to the other, reflecting as they do the best possible thought on the subject. The British Nitrogen Products Committee, appointed in June, 1916, to consider the establishment in Great Britain of some of the newer processes for fixing atmospheric nitrogen, has recently published its final report, and while a copy has not yet reached this office, we are enabled to review the salient features of the report from an abstract appearing in a late issue of the *Chemical Age* (London).

The recommendations of the Committee are significant in view of the program actually under way in the United States at the time of the Armistice. Calcium cyanamide is apparently recognized as the most likely fixed-nitrogen product that can be made on a commercial scale without further research or experimentation. The Committee recommends the establishment without further delay of a plant using this process on a scale sufficient to yield 60,000 tons of cyanamide per annum. The synthetic ammonia process and the oxidation of ammonia are recognized as yielding the greatest promise for the future, and the Committee recommends the establishment forthwith of the synthetic process "on a commercial unit scale and its expansion as rapidly as possible" to a production of 10,000 tons of ammonia per annum. Likewise, the ammonia oxidation process should be established on a scale sufficient to yield about 10,000 tons of nitric acid per annum.

With reference to power, the Committee's conclusion points quite logically to hydro-electric developments as the cheapest source on a large scale. Of more than ordinary interest is the Committee's conclusion that the present state of our knowledge on the application of low-temperature carbonization of coal as a preliminary to power production, in order to conserve ammonia and other byproducts, is not sufficiently encouraging to warrant the establishment of plants on a large scale.

Undoubtedly the development of a nitrogen-fixation industry in Great Britain, as in the United States, is vital to the national welfare. Great Britain's Committee is of the opinion that its development will require the active support of the Government. A similar question confronts the United States, and it will be necessary in the near future for our own Government to decide what its policy will be toward nitrogen-fixation in its relation particularly to the fertilizer industry in peace times. The report of the British Committee undoubtedly will be studied with profit as soon as copies are available for distribution in this country.

Industrial Research And New Technology

UP TO comparatively modern times the progress of industrial development was slow. Industrialists were confined mainly to the results of their own limited observations or to those of their immediate associates, and it was thus only by means of empiricisms, ideas unaided by even approximate theoretical conceptions, that any advancements were made in the industrial arts. There were no scientific or technical publications that carried knowledge to and fro through the isolating factory walls that secluded these men. They toiled alone; passed on their art through apprenticeship and left it practically as they had received it from their master. They were jealous minded, secretive and generally indisposed toward any changes being made in their art.

In recent times the progress of some of the industrial arts, through the aid of research and our present system of scientific co-operation, has been nothing less than revolutionary as well as exemplary for those still continuing to tread around on the same old spot where they started. The modern achievements in mechanics, electricity and chemistry as fruits of research need no elucidation here. But in order to show our readers some actual indication of the scope for the application of research to almost every variety of industry, we publish in this issue a brief exposition of the work now being carried on at the Mellon Institute. A year or two ago the administration of the Institute made an extensive inquiry to determine what expenditures were being made for research in the various industries of this country. Twenty million dollars was decided to be approxi-

mately the amount, one-half of which was expended in industrial laboratory investigations and the remainder on engineering developments.

Compared with other items to be found in our national budget, this research cost seems to have been kept at too conservative a figure, especially when it is considered from the point of view of what the credit column of this account would show if it were possible to assign a monetary figure to it. It is believed that a yearly return of at least $100,000,000 would not be too optimistic an estimate of it.

Industrial research is performed for gain, and to be properly evaluated should be run on sound business principles. This means that it should be charged for what it receives and credited for what it yields. Its expenditures should be so gaged that maximum gains will be obtained. To accomplish this, executive talent of the first order is required. If this were done, there is no doubt that it would be much more appreciated by the captains of industry, to whom only the balance sheets from their accounting departments are to be taken as navigating guides.

Carbon and Molybdenum As Producers of Flakes in Steel

PRACTICALLY all the evidence on flakes brought out at last winter's meeting of the American Institute of Mining and Metallurgical Engineers can be harmonized with the hypothesis that aside from deep-seated shrinkage cracks or strain cracks in ingots, the so-called flake—or its first cousin woody structure—in a finished piece is due to the presence of oxidized impurities of extreme tenuity. Several American metallurgists have expressed the opinion that flakes probably would be found in commercial steel of almost any composition if transverse testing would be regularly done, and with but two or three notable exceptions would not subscribe to the suggestion that the chemical specification was of determining weight in causing flakes. The French metallurgist J. J. COHADE, of Le Creusot, is a firm believer in the latter as being a very important factor, and his paper before the fall meeting of the British Iron and Steel Institute cites explicitly his experience that molybdenum or high carbon-nickel analyses engender woody fractures solely by virtue of the chemical composition. Woody structure thus appears in charges much less difficult to work sensibly free of inclusions than similar analyses lower in the objectionable elements but treated to give comparable tensile strengths.

English metallurgists were apparently as chary of accepting this conclusion as are their American brethren. For instance, in the discussion of Mr. COHADE'S paper Sir ROBERT HADFIELD and Dr. W. H. HATFIELD agreed that the quality of steel was largely influenced by the furnace and casting temperature, Dr. WALTER ROSENHAIN seconding them with the statement that high hearth heats and long high annealing will eliminate woody structures. In detail T. M. SERVICE notes that good armor required a high working temperature—and here he agrees with Mr. COHADE—a careful adherence to chemical specification, and a very fluid slag during the boil eventually to exclude solid non-metallic impurities. Steel cast at 1,560 deg. C. would therefore be much better than that cast at the more usual heat of 1,420 deg., while high forging temperature further aided in the production of superfine metal. E. H. SANITER, on the other hand, gave the opinion that woody structure was due to a state of strain existing in the steel, while W. H. DICKINSON thought that the original structure of the ingot was responsible, and that the effect of invisible inclusions was most important, the latter conclusion being supported by Dr. J. E. STEAD. Dr. GIOLITTI and COSMO JOHNS united in emphasizing the idea that while inclusions were doubtless responsible for defective transverse tests, the result was due not so much to the presence of the inclusion as to its effect on the surrounding metal.

Thus, much dissent was expressed to the hypothesis that carbon, nickel or molybdenum is a flake producer *per se*. Mr. COHADE himself probably aims to emphasize not so much the danger of carbon in steel as the effect chemical composition plays on segregation, since at the outset he quotes the first of four causes of woody structure as "mostly from the presence of non-metallic inclusions," and in the body of his paper he says of defective high-nickel steel that "it appears probable to the author that the improvement due to a lower percentage of carbon is the result of less segregation around the dendritic crystals formed during solidification, owing to the greater speed with which this takes place."

Apparently, in the case of carbon and nickel, segregation is again the culprit, so the difference between the author and his critics is less real than apparent. Perhaps, although Mr. COHADE is silent on this point, molybdenum acts as a litterer or a dispersing agent, as a very antithesis of scavengers or flocculators such as manganese or titanium; and its hesitant acceptance by meticulous tool-steel makers is due to this fact unconsciously rather than to a series of transverse tests.

Bribery of Dyers In Textile Mills

THE Federal Trade Commission gives out the news that complaints have been made against the United Chemical & Color Co., of New York, Andreykovicz & Dunk, Inc., of Philadelphia, the Arkansas Distributing Co., F. Bredt & Co., the New York Color & Chemical Co., the Franklin Import & Export Co., and the Heller & Merz Co., all of New York, alleging as follows: "That the respondents have been giving and offering to give to employees of both their customers and prospective customers, and their competitors' customers and prospective customers, without the knowledge or consent of their employers, sums of money" (and in some cases "and other gratuities") "as an inducement to influence their employers to purchase or contract to purchase from the respondents, dyestuffs, chemicals, etc., or to influence such customers to refrain from dealing or contracting to deal with competitors of respondents."

These are charges and not findings. So far as certain of the parties named are concerned we are convinced that if any efforts at bribery were made it was without the sanction of the men at the head. But that is not the affair of the Federal Trade Commission. Its duty is to try these complaints impartially, and, if it finds still in existence any continuations of the old habit of bribing the dyers, to call down the penalty of the law upon the offenders.

For many years this has been an infernal nuisance to the textile industry. It is a mean, underhanded trick, and its practice was very widespread. The color agent had to deal with the dyer, to teach him to use the dyes, to "make it right with him," and to leave

him satisfied. The easy way is to give him a rebate which is charged to the consumer—and the dyer is used to it. Without doubt a considerable number of these precious crooks declare that everybody else is offering these presents, and of this the salesman is finally persuaded. Bribery was a standard feature of German commercial practice, "and," as an old dyesalter said, "they didn't even know it was wrong. The rest of us did—but we bribed the dyers all the same."

We know of one concern that has laid down the law to its entire force that under no circumstances or provocation shall any kind of so-called "gratuity" be paid, and we understand that a goodly number of others hold to the rule. To break it is to offend against the law and to encourage dishonesty. There is nothing in the practice of the dyer's art to make him less dependable than other men except this German tradition, and if dyers as a class are so poor in spirit that they cannot stand up against it we hope that manufacturers and dealers will be made to find it unprofitable to give in to them. The whole country has a business reputation to make in some things, and to bear in all things, and it will not do to let a lot of hold-over dyers with itching palms jeopardize its fair name.

Maybe the textile industry will see a light some day and induce textile chemists to supervise their tinctorial work instead of working by the rule-of-thumb methods of some boss dyer who learned his trade and his cupidity in secret from some one no better than himself. If a chemist indulges in such practices he is guilty of unprofessional conduct and there is abundant warrant to expel him from any learned society.

Business Men For Exalted Positions

In proportion to one's labour, eminences are gained; and he who seeketh eminence passeth sleepless nights.
Whoso seeketh eminence without labouring for it, loseth his life in search of vanity.

WELL applied, indeed, are the words of the Arabian poet to the conduct of life in these times, and most aptly fitted to the career of the present-day politician. There is a call for men who study and know the factors that influence our economic and industrial life. Business men are needed in administrative government positions from the President down. The most hopeful prospect is HERBERT HOOVER.

Wages and Hours In Steel Industry

THE 10 per cent wage advance to common labor, announced by the United States Steel Corporation as effective February 1, may be readily interpreted as indicating that the Steel Corporation has no present intention of eliminating the twelve-hour shift, which now applies to something like 20 per cent of the total number of men employed in the iron and steel industry. It is easily recognized that were the elimination of the twelve-hour shift feasible in other respects, it would be necessary to compromise matters with the men involved by paying them a larger rate per hour for the smaller number of hours of employment provided, and the time when the employer is disposed to accept a higher labor cost or feels that the workmen require an improvement in their condition is the natural time for such a compromise.

Under the rate for common labor that obtained in the iron and steel industry from August 1, 1918, to February 1, 1920, 42 cents an hour, and with the "eight-hour basic day" established October 1, 1918, the man who is on duty twelve hours is paid fourteen times the hourly rate, while with the same rate for an eight-hour day he would be paid for eight hours' time, or only 58 per cent as much. Obviously, such a change would make an impossible condition for the man. Under the expiring rate, a man working twelve hours and being paid for fourteen hours' time received $5.88, making $11.76 for two men, to complete the twenty-four-hour cycle. A straight 10 per cent wage advance increases this to $12.94. The same sum distributed to three men, thus leaving the labor cost unchanged, would give $4.31 to each man, this being 27 per cent decrease in the day's earnings instead of 42 per cent, therefore constituting a long step toward a compromise.

In order to employ three men in place of two an extra man must be found, and the Steel Corporation management was evidently of the opinion that this would be difficult if not impossible, while it is fair also to presume that it was known that the men individually do not wish the change, that as a rule they prefer to work the long hours and receive the correspondingly greater pay. Such conclusions are important, since there is no reason to doubt either that the Steel Corporation desires to be fair with its workmen or that it is very well informed as to labor conditions and the attitude of the men.

The incident furnishes no ground for a conclusion that abolition of the twelve-hour day is to be postponed forever. We are in a transitionary condition. There is a shortage of labor in the sense that there are more jobs seeking men than there are men seeking jobs. There is much reason to doubt whether there is a shortage of ability on the part of the workers in the United States, taken as a whole, to do the work that is seeking to be done. Probably the time will come when men individually will be willing to work harder, and then the iron and steel industry may be able to obtain more men.

In another sense there is a transitionary condition. The common labor of the iron and steel industry has been very largely foreign born in the past, and the supply of such labor is practically shut off. Eventually men with different ideas as to the length of time they are willing to be on duty will have to be employed to operate the blast furnaces and steel mills. Those men may prefer to work eight hours for eight fourteenths, or ten hours for eleven-fourteenths, as much money as for twelve hours. Were such a time to come the problem would solve itself with no effort by employers.

There is no occasion to fear that at any time in the future there will be a protracted shortage of labor in the iron and steel industry such as would prevent the furnishing of supplies desired by consumers. The amount of labor involved in making a ton of finished rolled steel is so small relative to the industrial value of the steel that it will always be commercially feasible for the iron and steel industry to bid the prices necessary to obtain the labor. A large amount of labor is required in the consumption or employment of steel. In case of competition for labor, the typical consumer of steel is more likely to find his own labor cost prohibitive than to find the cost of the steel prohibitive, if enhanced only by the necessary increase in the labor cost of producing that steel. Market conditions never remain unchanged long enough to enable the economic law to work out the result.

The Eventual Retort Plant for the Distillation of Oil Shales

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a recent article entitled "The Eventual Retort Plant for the Distillation of Oil Shales," by Louis Simpson (CHEM. & MET. ENG., vol. 22, p. 71), there appears the following staggering statements:

"It is, however, now known that to obtain the recovery of the maximum yield of nitrogen as ammonia gas, every particle of the spent shale should be exposed to a temperature of 1,125 deg. C., or 2,060 deg. F. It is also known that a decrease of comparatively few degrees of temperature will result in a very large and entirely disproportionate decrease in the yield, while an increase in temperature over the critical temperature increases the yield only slightly."

I seriously doubt the veracity of those assertions. According to Ramsay and Young, ammonia commences to decompose into its elements at about 500 deg. C. under the most favorable circumstances, and on passing the gas through a porcelain or iron tube the decomposition is *complete* before 800 deg. C. is reached, the actual temperature being about 780 deg. C. The temperature of 1,125 deg. C., mentioned by Simpson as the most favorable for a maximum ammonia yield, would disintegrate the NH_3 molecule with great violence, and it would be impossible for the elements (N_2 and H_2) to recombine to any appreciable extent under the conditions he assumes, because of the peculiar physical nature of the equilibrium represented by the equation

$$N_2 + 3H_2 \leftrightarrows 2NH_3.$$

This reaction is exothermic, therefore a high temperature will inevitably shift the equilibrium to the left, and the absence of pressure aids this decomposition, because the formation of ammonia is attended by a contraction in volume, while its decomposition proceeds with an increase in volume. This is merely an application of the principle of Le Chatelier. (See also F. Haber, *Zeit. für Etektrochemie,* vol. 16, p. 244.) Even under the most favorable conditions, hydrogen and nitrogen combine to ammonia very slowly, unless the velocity of the reaction is increased by the use of a catalyst. Hence it is self-evident that the physical conditions which Simpson suggests as ideal would play havoc with the ammonia molecule, and make the yield of this product practically zero. ARTHUR J. FRANKS.

Colorado School of Mines,
Golden, Col.

To the Editor of Chemical & Metallurgical Engineering

SIR:—The reaction cited by A. J. Franks is doubtless correct, so far as the decomposition of *pure* ammonia is concerned, but the problem, in the case criticized, is different and involves the claimed decomposition of ammonia, diluted in steam and other gases.

Dowson claims that at low temperatures only a small percentage of steam decomposes, and it is only with the decomposition of steam that the formation of ammonia, when treating oil shales, becomes possible.

The ammonia produced by the decomposition of steam, in the presence of nitrogen, does not remain subjected to the high temperatures needed to secure the decomposition of the steam used, the combination taking effect in the presence of an excess of steam and of other gases.

Since the war, German chemical literature teems with information as to the influence of steam and other gases upon this and similar combinations of gases.

Were Mr. Franks' ideas correct in practice, it would be possible to secure a maximum recovery of ammonia only through the use of a very great excess of steam. The Scotch practice demonstrates, and demonstration is safer to follow than any theory, which, as in this case, may be incorrectly applied, that there is something not sound in Mr. Franks' contention.

Whether the 1,125 deg. C., mentioned by me, be too high a temperature or not is really of small consequence at this moment. It is known that the Scotch retort could not stand up against the high temperature required for a maximum yield of ammonia, so it was necessary to devise a plant that would stand up. If my plant will stand up against 1,125 deg. C., and a temperature much lower than 1,125 deg. C. is required, so much the better. The chemical reaction employed is not different from that used in Scotland for many years, with more or less success, so that a plant that will satisfactorily endure the highest temperatures used in the Scotch retort, and even higher, and which is so designed that the heat can be regulated and also applied more regularly and intimately, must of a necessity be an improvement. LOUIS SIMPSON.

Ottawa, Canada.

Resistance of Absorption Tower Packing to Gas Flow

To the Editor of Chemical & Metallurgical Engineering

SIR—In my paper on "Resistance of Absorption Tower Packing to Gas Flow," printed in your number of Dec. 24-31, an error occurs on page 766.

You have printed formulas 1 and 2 as:

$$p = \frac{ks^2}{v}$$

and $s = a$

respectively, whereas they should read:

$$p = ks^2$$

and $s = \frac{v}{a}$

Wilmington, Del. FRED C. ZEISBERG.

Cellulose Symposium

To the Editor of Chemical & Metallurgical Engineering

SIR:—Will you let me make the correction of the little slip made on page 708, vol. 21, of CHEMICAL & METALLURGICAL ENGINEERING? In this you report me as saying that "the art of hydration of paper making fiber has not yet been discovered." Of course the art of hydration by mechanical means has been known for a long time, but I was endeavoring to point out the desirability of substituting the use of chemicals to replace part of the long mechanical treatment now necessary in the manufacture of such papers as grease-proof and glassine. My conclusion was that although many suggestions have been made, no one has succeeded in making the chemical hydration of wood pulps a commercial success. W. P. COHOE.

New York, N. Y.

Hoover for President

To the Editor of Chemical & Metallurgical Engineering

SIR:—In accordance with the instructions of the Joint Council of Engineers of San Francisco, I have the honor to transmit to you copy of a resolution hereto attached, favoring the "Hoover for President" movement. It is the intention of the Joint Council, in forwarding this letter and its accompanying resolution to engineering organizations throughout the United States, to arouse engineers generally to the importance of having for our next Chief Executive of the nation a man of proved administrative ability, unquestioned integrity and absolutely free from partisan politics.

Engineers can well appreciate the exceptional fitness of Mr. Hoover for President, and through their organizations are in a position to form the nucleus of a non-partisan movement to improve materially the running of the biggest business organization in the world—the Government of the United States. C. H. SNYDER,
Secretary Joint Council.

The following is the resolution unanimously adopted by the Joint Council of Engineers of San Francisco, Jan. 13, 1920:

> Whereas there is at this time a strong and widespread sentiment for Herbert C. Hoover for President of the United States as an independent candidate, free from political deals and pre-election pledges; and
>
> Whereas Mr. Hoover, by his work in Europe, has shown executive and administrative abilities of the highest order, particularly fitting him for handling both the economic problems of reconstruction at home, and our relations with other nations; and
>
> Whereas the Joint Council of Engineers of San Francisco has a patriotic duty to perform at this time, not only as representing engineers, but also as a representative body of American citizens; be it therefore
>
> *Resolved*, That the Joint Council of Engineers of San Francisco, representing 2,000 engineers in the Bay district, indorses Herbert C. Hoover for President and invites the engineering bodies of the United States to join with it in forming an organization to further Mr. Hoover's election, and in such other activities as will insure the affairs of the nation being handled on an efficiency and non-partisan basis, and be it further
>
> *Resolved*, That copies of this resolution be sent to all engineering organizations and technical journals throughout the United States, and that such other steps be taken as will further the movement of "Hoover for President."

Spring Meeting of the American Electrochemical Society

Plans for the meeting of the American Electrochemical Society in Boston, April 8, 9 and 10, are maturing rapidly and give promise of an excellent meeting. Joint sessions will be held with the American Institute of Electrical Engineers on the subject of electric-furnace alloys and power for electrochemical purposes. A symposium on the regular program will cover the subject of colloid chemistry. Among the trips already planned is one to the General Electric Co.'s plant at Lynn, to inspect the manufacture of the tungar rectifier and the kenetron tube. Headquarters will be at the Copley-Plaza Hotel.

Chemical Warfare Service

No change was made by the Committee on Military Affairs in the Chemical Warfare section of the Army reorganization bill when it was reported to the Senate. The exact language drafted by the sub-committee in providing for a separate Chemical Warfare Service is part of the bill which is now before that body.

A.I.M.E. Annual Meeting

A CIRCULAR has been issued giving the program of the 121st meeting of the American Insitute of Mining & Metallurgical Engineers, to be held in New York City, Feb. 16 to 19, 1920. Programs of interest to metallurgists will be held as follows:

Non-Ferrous Metallurgy, Institute of Metals Division, Tuesday, Feb. 17, 10:30 a.m. Papers to be presented: Intercrystalline Brittleness of Lead, by H. S. Rawdon; A Peculiar Type of Intercrystalline Brittleness of Copper, by Henry S. Rawdon and S. C. Langdon; Relationship of Physical and Chemical Properties of Copper, by Frank L. Antisell.

Milling and Smelting Session, Tuesday, Feb. 17, 2 p.m. Papers to be presented: Volatilization in Assaying, by Frederic P. Dewey; Reverberatory Furnace for Treating Converter Slag at Anaconda, by Frederick Laist and H. J. Maguire; Coal Pulverizing Plant at Nevada Consolidated Copper Smelter, by R. E. H. Pomeroy; Milling Plant of the Alaska Gastineau Mining Co., by E. V. Daveler.

Iron and Steel Sessions, Wednesday, Feb. 18, 10 a.m., and 2 p.m. Papers to be presented: Blast-Furnace Flue Dust, by R. W. H. Atcherson: Manufacture of Semi-Steel for Shells, by Frank E. Hall; An Experiment in One-Piece Gun Construction, by P. W. Bridgman; Tensile Properties of Boiler Plate at Elevated Temperatures, by H. J. French: Microstructure of Iron and Mild Steel at High Temperatures, by H. S. Rawdon and Howard Scott; Physical Changes in Iron and Steel Below the Thermal Critical Range, by Zay Jeffries; Graphitization of White Cast Iron, by R. S. Archer; Application of the Microscope to the Malleable-Iron Industry, by Enrique Touceda.

Alloy Steels Session, Wednesday, Feb. 18, 2 p.m. Papers to be presented: The Coefficient of Expansion of Alloy Steels, by John A. Mathews; Critical Ranges of Some Commercial Nickel Steels, by Howard Scott; Forgeability of Iron-Nickel Alloys, by T. D. Yensen.

Among other papers included in the program are the following: Rise and Decline in Production of Petroleum in Ohio and Indiana, by J. A. Bownocker; Petroleum Resources of Kansas, by Raymond C. Moore; Rôle of Bed-Rock in the Distribution of the Hydrocarbons, by M. M. Monte-Flores; Water Displacement in Oil and Gas Sands, by Roswell H. Johnson; Oil Fields of Kentucky and Tennessee, by L. C. Glenn; Petroleum in the Philippines, by W. D. Smith; A Résumé of the Pennsylvania-New York Oil Field, by R. H. Johnson and Stirling Huntley; Petroleum in the Argentine Republic, by Stanley C. Herold; A Foreign Oil Supply for the United States, by George Otis Smith; Petroleum Resources of Great Britain, by A. C. Veatch; Geologic Distillation of Petroleum, by Bailey Willis; International Aspects of the Petroleum Industry. by Van H. Manning; The Composition of Petroleum and Its Relation to Industrial Use, by C. F. Mabery; Low-Temperature Carbonization of Coal, by S. W. Parr and T. E. Layng; Examination of Ores and Metals in Polarized Light, by Fred E. Wright.

Registration will begin, as usual, at 9 a.m. at the Institute headquarters. Lunches will be served daily at the Engineering Societies' Building. The smoker, which has become an institution, will be held for the members and male guests on Monday evening—during this time the ladies will attend a theater party. Tuesday evening the banquet will take place, while Thursday

an excursion will be taken to the Bush Terminal, Brooklyn.

Institute of Metals Division members are requested to make their headquarters at the Hotel Seville, Madison Ave. and 29th St. This hotel served the Division nicely last February. It will be glad to do so again this year and the members of this Division find special advantages in being together.

The ladies who are visiting the meeting with members are especially invited to attend the luncheons, the banquet, and other functions which have been arranged by the Ladies' Committee for each day of the meeting. An Entertainment Committee from the Ladies Auxiliary, headed by Mrs. Arthur S. Dwight, has prepared a very attractive program which will insure them a pleasant stay.

Bill to Prohibit Export of Helium

Exportation of helium is prohibited without special permit in the draft of the bill which has been submitted to Congress by the Secretary of the Navy. The President is authorized by the bill "to prescribe appropriate rules and regulations to govern the exportation of helium." Exportation of that gas without such a permit is to be punishable by imprisonment for not more than 5 yr. and not less than 1 yr., or by fine of not less than $5,000, or both. Secretary Daniels in recommending the adoption of the measure wrote to the chairman of the Interstate and Foreign Commerce Committee as follows:

"The sources of supply of helium in the United States are not numerous and the quantity obtainable is very much limited. This gas is non-inflammable and is consequently of inestimable value for balloons of all kinds and especially for those of the dirigible types that the Navy Department is endeavoring, under authorization by Congress, to develop and bring to a state of greatest efficiency.

"It is manifest therefore that the public interests imperatively require conservation of the supply of this gas, as the demand for it abroad is insistent and great enough to consume, in all probability, within a short time the available supply in this country.

"The accompanying draft of a bill would admit of the control of the supply of this gas so that the interests of the Government would be given the maximum of protection so far as affected by this matter."

Criticism of Government Expenditures at Muscle Shoals

Government nitrate plants at Muscle Shoals, at Toledo, and at Cincinnati came in for particularly severe criticism at a hearing Feb. 3 before the Graham committee of the House of Representatives. The author of the more serious charge of inefficiency in the handling of the Muscle Shoals project is Fred H. Wagner of Johns Hopkins University. Mr. Wagner formerly was a Lieutenant Colonel in the Ordnance Department and from July, 1918, to May, 1919, was Director of Operations at Muscle Shoals. Patriotism was forgotten at Muscle Shoals, Colonel Wagner asserts. Extravagance not only was permitted but was encouraged, he says. Among points brought out by Colonel Wagner was the fact that a number of former New York City officials held some of the more prominent official positions connected with the Muscle Shoals work. These officials, whom he named, formerly were connected with the New York Fire Department, Street Cleaning Department, and other municipal activities which were in no way connected with the chemical industry.

Colonel J. W. Joyes of the Nitrate Division of the Ordnance Department was called before the committee to explain the purchase of a limestone quarry at Waco, Ala., thirty miles from the Muscle Shoals plant. It had been charged that this action on the part of the Government had put private enterprise engaged in lime industries out of business. Colonel Joyes explained that the purchase was necessary in order to have an absolutely reliable source for limestone.

Hugh L. Cooper, who was connected with the construction of the Keokuk dam, with a large plant at Niagara Falls and other important projects, testified to the effect that he had been recalled from service in France to make an examination of the Muscle Shoals project and had spent three months there. He made recommendations as to changes which were adopted. He expressed the opinion that with a free hand he could have built the Muscle Shoals plant in three years. The Government's estimate was six years. He also stated that four or five years probably will be required to complete the Muscle Shoals plant. He explained the difficulties involved in a 24-hr. use of power as necessary in the production of nitrate as compared with the 10-hr. period for which power is required for industrial purposes in the area supplied by the Keokuk power plant.

The Government is likely to lose nearly $15,000,000 if the Toledo (Ohio) nitrate plant should be salvaged at this time, is the opinion of Henry G. Tyrrell of New York, who also appeared before the committee. Mr. Tyrrell is a member of a firm of plant appraisers. He attempted to appraise both the Toledo and Cincinnati plants for the Government. Before the work was completed he was recalled to Washington and is still awaiting orders which never came. He attributes his separation from the work to the fact that his figures differed so widely from those of the War Department. He also stated that his efforts to appraise these plants were hampered by the failure of the officials to cooperate. He expressed the opinion to the committee that both the Toledo and Cincinnati plants were in unsuitable locations, as is the picric acid plant at Little Rock. At the time these locations were chosen it was done to satisfy certain influential interests as well as to scatter the plants to avoid congestion.

Institution of Mining and Metallurgy Awards Medals

The following awards have been made by the Institution of Mining and Metallurgy (London):

Gold Medal of the Institution (premier award) to H. Livingstone Sulman, M.Inst.M.M., in recognition of his contributions to metallurgical science, with special reference to his work in the development of flotation and its application to the recovery of minerals.

"The Consolidated Gold Fields of South Africa, Ltd.," Gold Medal to William Henry Goodchild, M.Inst.M.M., for his papers on "The Economic Geology of the Insizwa Range" and "The Genesis of Igneous Ore Deposits."

"The Consolidated Gold Fields of South Africa, Ltd.," Premium of Forty Guineas to Dr. Edward Thomas Mellor, M.Inst.M.M., for his paper on "The Conglomerates of the Witwatersrand."

A Compendium of Chemical and Physical Constants

ONE important outcome of the war is the recognition that the United States of America must take a more active part in scientific work than ever before. America has done wonderful things in chemistry, physics and other branches of science, but in spite of this she has not been accorded recognition as a scientific nation. What is more, America serenely accepted the world's estimation and made no effort to get her just dues. This fact we accepted so absolutely that no teacher of the science thought his education complete unless he received a degree after taking a course of study in some foreign university. And many a man has gone to get a foreign education which might or might not be better than that which he could have obtained in this country, simply for the éclat which a foreign diploma gave him. Few non-scientific people realize that the best and most complete works on chemical and physical constants are written in German. To be sure, these are woefully out of date in many respects and they are perhaps known as much for the vast amounts of fundamental knowledge which is missing as for what is contained therein. Much of the knowledge contained therein is incorrect and many divergent values are given without any critical comment to enable the searcher to pick the right one. They are poorly indexed and abominably compiled. But in spite of all these drawbacks and many others which might be mentioned, they are still the most complete source of information gathered in one volume. Being written in German they are hard to understand and American industry because of this fact obtains only a fraction of the matter available therein.

German Literature an Aid to Allies in the War

A fact which is not generally known is that during the war the colleges, universities and the industries were combed for copies of Landolt and Börnstein's Tabellen, and that hundreds of these works were in daily use in the Army, Navy, Airplane and Medical Departments, to say nothing of those used by the Council of National Defense, National Research Council, Shipbuilding and Explosive Departments and many other departments too numerous to mention here. Many Germans figure that it was their literature that defeated them in this war.

It is proposed to issue a critical compendium of chemical and physical constants, which shall be up to date and correct; and which shall contain such new constants as can be determined before the time of publication as well as many which have been determined but which are not now generally available.

Decision to Publish Tables

At a meeting of the Inter-Allied Chemical Conference held in London, July 14-17, 1919, there was formed an International Union of Pure and Applied Chemistry, and it was voted that "Critical tables of physical and chemical constants shall be published in the United States and there shall be created an American publication committee charged with the general organization and the prosecution of the work."

At the meeting of the International Research Council held in Brussels on July 22, 1919, the International Union of Pure and Applied Chemistry became the Chemical Section of the International Research Council. The vote in regard to the publication of critical tables of physical and chemical constants was confirmed by the Chemical Section and by the Physical Section.

Board of Trustees Appointed Here

This work has been undertaken by the National Research Council in co-operation with the American Chemical Society and the American Physical Society. The business arrangements are to be in the hands of a board of three trustees: Mr. Hugh K. Moore, chairman, (appointed by the National Research Council); Mr. Julius Stieglitz, (appointed by the American Chemical Society); Mr. Edward P. Hyde, (appointed by the American Physical Society). By a vote of the National Research Council, these gentlemen have been authorized to raise by subscription $100,000 and as much more as may be found necessary in order to meet the probable deficit which will result from carrying out the task assigned to the United States by the International Research Council.

Aid Asked in the Tremendous Task

It will be seen that America has undertaken a tremendous task. All our colleges have certain information which they can impart. There is a vast amount of knowledge in the research laboratories of the industries. It will be the duty of those in charge to collect and tabulate all this information. Not only this, but an effort will be made to obtain from the business concerns of the country a list of the physical and chemical constants which they require in their business and as far as possible have these determined and included in the work. The information contained therein will be of immense value to all industries using chemical or physical processes.

It is hoped that when manufacturers are approached for funds they will contribute liberally. It is not only good business to support this movement, but it is a patriotic duty. How can the United States hope to be a leader in scientific development, if everyone has to go to foreign publications for information?

In fact, it appears already as though even this information will no longer be all available, since it is reported that there is a movement on hand to prevent the exportation of any more German scientific literature. It is therefore becoming increasingly important that the United States should not only be self-sustaining in regard to this matter, but should take the leadership.

Civil Service Examinations

The Civil Service Commission announces the following examinations:

Associate physicist qualified in physical metallurgy, for men only, at salaries ranging from $2,000 to $2,800 a year. Applications will be received until further notice.

Assistant physicist qualified in physical metallurgy, for men and women, at salaries ranging from $1,400 to $1,800 a year. Applications will be received until further notice.

Pyrotechnic engineer. Duties will be to assist in development of design, test and manufacture of military pyrotechnics, and, in addition, will be those of an observer and firer from aircraft. Salary: Grade 1, $2,400 a year; Grade 2, $3,600 a year. Apply on Form 1312 before Feb. 17.

Proposed Substitute for Dye Licensing System

WHILE the last word has not been heard in the controversy over the licensing of dye imports, it seems certain that the main objections of the opponents of this plan have been met by the modifications now under consideration by the sub-committee. The sections referring to the licensing system in the original Longworth bill[1] have been striken out and replaced by the United States Tariff Commission's plan. The final wording is still uncertain, as Joseph H. Choate, Jr., has suggested certain changes.

Changes in Dutiable List

The following articles have been removed from Group III., sec. 500, that is, the finished product group, for which a duty of 45 per cent ad valorem is provided:

Natural alizarin and natural indigo, and colors, dyes, stains, color acids, color bases, color lakes, leuco-acids, leuco-bases, indoxyl and indoxyl compounds obtained, derived or manufactured in whole or in part from natural alizarin or natural indigo; natural methyl salicylate or oil of wintergreen or oil of sweet birch; natural coumarin.

In place of these natural products the following higher sugars have been substituted:

Adonite, arabinose, dulcitol, galactose, inosite, inulin, levulose, mannitol, mannose, melezitose, raffinose, rhamnose, sorbitol, xylose, and other of the higher saccharides required for scientific purposes.

Tariff Commission Plan

The new section 504 provides that no article on the dutiable list shall be imported into the United States unless the Tariff Commission shall determine that such article (or a satisfactory substitute) is not obtainable in the United States on reasonable terms as to quality, price and delivery, and that the article is required for use by an actual consumer in the United States. In addition, Mr. Choate proposes that the Tariff Commission prepare, after investigation, a list, to be known as the importable list, of such products as may be found by it to fulfill the above requirements for admission to import.

The phrase "reasonable terms as to price" for any article is defined as the lowest price, for the time being, which, in the judgment of the Tariff Commission, shall be sufficient to insure the maintenance in the United States of the production of such article by an efficient plant operating on a substantial commercial scale.

Suggestions as to Procedure

All details as to practice and procedure are to be determined by the Tariff Commission. Mr. Choate suggests that such rules and regulations shall be so framed as to prevent the importation of any article in quantities sufficient to discourage manufacture of the same in the United States, or to provide any consumer with supplies from any source exceeding his needs for six months in advance, or to cause an accumulation in the United States of more than a six months' supply for the country as a whole.

Extension of War Trade Board Licenses

Notwithstanding the prior termination of the present war the provisions of the trading with the enemy act are to be continued for ninety days after the date of the taking of effect of this act and all individual licenses issued by the War Trade Board section of the State Department during this period are to remain in effect. At the end of this period all records, etc., relating to individual import licenses for articles on the dutiable list are to be turned over to the Tariff Commission.

For the purpose of enforcing this act, the Tariff Commission has the right to demand from manufacturers, dealers and importers sworn statements as to production, stocks on hand, cost of production, price, etc. Such information shall be confidential, of course, and shall not be published except in the form of tables, averages and summaries which shall not disclose the operations of individual domestic manufacturers.

[1] H. R. 8,078; Sec. 503(a) to 503(d) inclusive, Sec. 504. The bill passed the House of Representatives Sept. 26, 1919, and was referred to the Senate Committee on Finance Sept. 29, 1919.

American Chemical Society, Chicago Section Meeting

The January meeting of the Chicago Section of the American Chemical Society was held at the City Club, Jan. 16. The principal speaker of the evening was Dr. Clarence W. Balke, who spoke to the members on the metallurgy and manufacture of tungsten.

Dr. Balke covered at considerable length the process of manufacture employed at the Fansteel Products Co.'s works in North Chicago, a full description of the operation of which was published in the Jan. 7 issue of Chemical & Metallurgical Engineering.

New York Section, A. I. M. E., Elects Officers

At the regular February meeting of the New York Section of the American Institute of Mining and Metallurgical Engineers held on Feb. 4, the following officers were elected for the ensuing year: Chairman, E. P. Mathewson; vice-chairmen, William Y. Westervelt and D. M. Liddell; treasurer, E. L. Gruver; members of the executive commitee, S. H. Ball and A. F. Keene.

The subject of the meeting was Foreign Trade. The speakers were G. A. O'Reilly, of the Irving National Bank, and V. Gonzalles, of the Mercantile Bank of the Americas, and Dr. John F. Crowell, of the R. G. Dun Co.

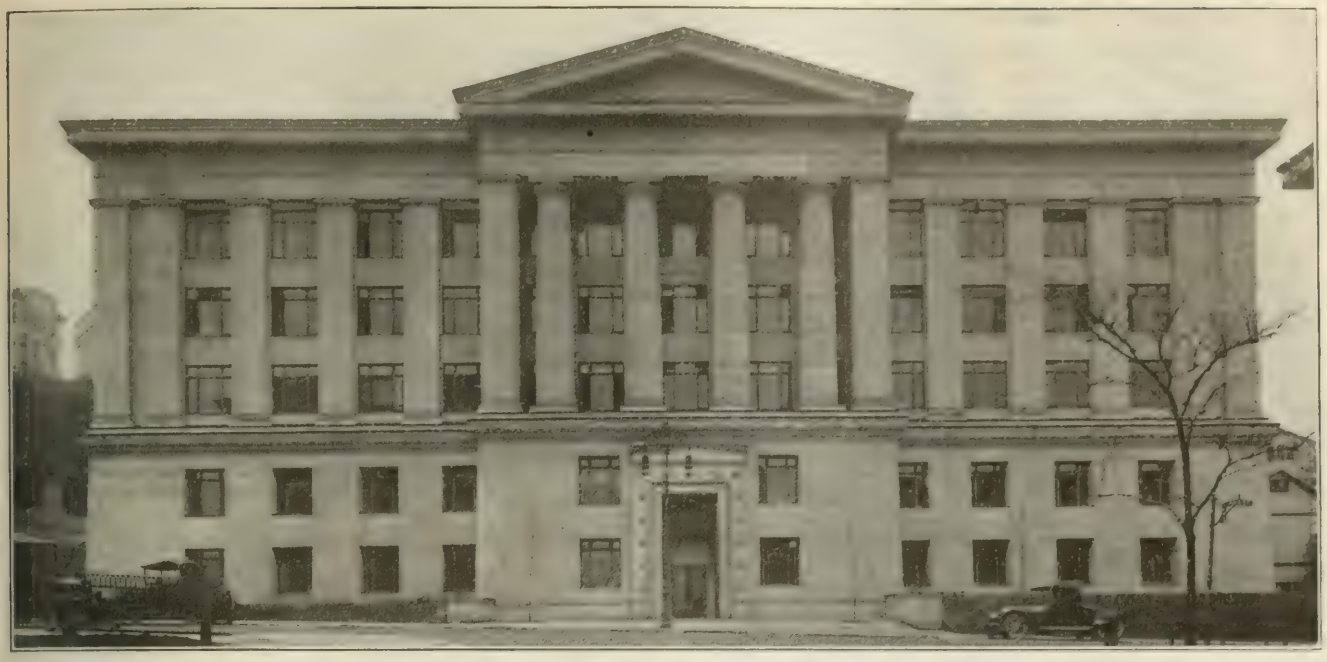
Stretched Wire Apparatus for Measuring Thermal Expansions

An unfortunate piece of printers' pi was dished up to the readers of A. W. Gray's article on the above subject in Chemical & Metallurgical Engineering of Nov. 26-Dec. 3, 1919, prepared during the printers' strike. The matter immediately preceding the first subtitle on page 668 should read:

"Molybdenum repeats better than most substances, and is, therefore, well suited for exhibiting the reliability of expansion apparatus.

"The precision easily attainable with stretched wire expansion apparatus is also well illustrated by the routine practice of plotting to a large scale the deviations of individual measurements from the quadratic which best represents an entire series. This method is useful not only for adjusting observations, but also for locating transition regions with precision, as can be seen by examining the deviation curves published by Merica and Schad."

On page 670 the word "or" in line 16 of the first paragraph should have been "of." In the seventh line of the last paragraph of this section the fraction "$\frac{5}{4}$" is omitted before the words "the expansion of *AJ*."



MELLON INSTITUTE OF INDUSTRIAL RESEARCH

Industrial Research at the Mellon Institute

A Concise Account of the Fellowship System of Industrial Research—Developments in Bread, Laundering, Refractories, Dental Cements, Magnesia Insulation, Insecticides, Protected Metals, Paper Containers, Flotation, and Testing of Leather Belting

By WALLACE SAVAGE

BEING inquisitive to know just what the accomplishments were that had created the great repute in industrial circles of the Mellon Institute of Industrial Research in its brief eight years of activity in Pittsburgh, the writer made a survey of the pertinent literature. Reviewing backwards, the first clue was found in "Some Present-Day Problems of Chemical Industry."[1] Here was listed a selection of problems such as are taken at the Institute for investigation, together with a few preliminary general remarks on the methods of industrial research. Being in quest of solved problems, "The Industrial Fellowships of the Mellon Institute"[2] was scrutinized next. The progressive growth in the number of industrial fellowships and fellows, together with the increase in contributions, shown

TABLE I. ANNUAL RECORD

March to March	Number of Fellowships	Number of Fellows	Amounts Contributed
1911–1912	11	24	$39,700
1912–1913	16	30	54,300
1913–1914	21	37	78,700
1914–1915	21	32	61,200
1915–1916	36	63	126,800
1916–1917	42	65	149,100
1917–1918	42	64	172,000
1918–1919	47	77	238,245

in this report, as recorded in Tables I and II, was certainly excellent evidence of the merits of the industrial fellowship system, in even a greater measure than the founder, the late Dr. Robert Kennedy Duncan, had ever predicted in his writings.[3] However, after examining the indexes of several of the publications especially representing industries having fellowships, it soon became apparent that the reports on the findings were voluminous as well as widely scattered, and that the most convenient source for the desired information was to be had by direct interview with the directors and the industrial fellows of the Institute.

Organization and Administration

In the spring of 1913, Andrew W. and Richard B. Mellon gave a sum of money which was sufficient to erect a substantial home, purchase a large amount of equipment and supply an annual income of $65,000. At present about $250,000 are received from the fellowship donors, making the total available funds $315,000 per annum. While the Institute is operated as a part of the University of Pittsburgh, it is independent financially and under its own management. The functions of the administrative organization are shown in the chart.

In establishing an industrial fellowship, an agreement is made between the donor and the director of the Institute, in which the donor agrees to furnish a stated amount of money, the expenditure of which shall be limited to his problem and for which he shall receive exclusive title to any results obtained. Assignments to all patents on inventions made during and germane to the fellowship are made by the fellow to his donor. The

TABLE II. INDUSTRIAL FELLOWSHIPS IN OPERATION, 1919

Numbers and Names of Industrial Fellowships	Industrial Fellows, Names and Degrees	Foundation Sums and Dates of Expiration
117—Window Glass	(Fellow to be appointed)	$3,000 a year. Bonus: $2,000.
127—Collar	H. D. Clayton (B. A., Ohio State University)	$2,800 a year. June 14, 1919.
129—Illuminating Glass	A. H. Stewart (B. A., Washington and Jefferson College)	$2,100 a year. October 1, 1919.
145—Soap	(Fellow to be appointed)	$2,000 a year.
150—Enameling	R. D. Cooke (M. S., University of Wisconsin)	$2,600 a year. April 1, 1919.
151—Leather Belting	P. G. McVetty (M. E., Cornell University), senior fellow	$4,900 a year. April 1, 1919.
	R. H. Edson (B. A., Clark College)	
152—Refractories	R. M. Howe (M.S., University of Pittsburgh), senior fellow	$7,000 a year. May 1, 1919.
	B. M. Burchfiel (B.A., Southwestern College). E. N. Jessop (B.S., University of Pittsburgh). S. M. Phelps (assistant).	
153—Canning	M. R. Daughters (M.A., University of Nebraska), (second fellow to be appointed)	$6,000 a year. May 1, 1919.
154—Paper	Howard Curtis (B.A., Washington and Jefferson College)	$2,175 a year. June 1, 1919.
155—Protected Metals	J. H. Young (Ph.D., Ohio State University)	$3,000 a year. June 1, 1919.
156—Physiological Research	K. K. Jones (M.S., Kansas State Agricultural College)	$4,000 a year. August 1, 1919.
157—Dental Products	C. C. Vogt (Ph.D., Ohio State University)	$2,000 a year. July 1, 1919. Bonus: Royalty on sales.
158—Leather soling	C. B. Carter (Ph.D., University of North Carolina)	$3,500 a year. June 1, 1919.
159—Copper	C. L. Perkins (B.S., New Hampshire College)	$5,400 a year. July 1, 1919.
	R. E. Sayre (M.S., University of Wisconsin)	
160—Oil	W. F. Faragher (Ph.D., University of Kansas), senior fellow	$10,000 a year. Sept. 1, 1919.
	W. A. Gruse (Ph.D., University of Wisconsin)	Bonus: $10,000.
161—Glass	R. R. Shively (Ph.D., University of Pittsburgh)	$4,000 a year. Sept. 1, 1919.
162—Gas	J. B. Garner (Ph.D., University of Chicago), senior fellow	$7,500 a year. Sept. 15, 1919.
	H. B. Heyn (B.S., University of Wisconsin).	
163—Aluminum	E. O. Rhodes (M.S., University of Kansas), senior fellow	$6,500 a year. Sept. 15, 1919.
	R. B. Trusler (B.S., Syracuse University).	
164—Alloy	O. E. Harder (Ph.D., University of Illinois)	$3,500 a year. Oct. 1, 1919.
165—Coffee	C. W. Trigg (B.S., University of Pittsburgh)	$2,250 a year. Oct. 1, 1919. Bonus: 2 per cent of gross profits.
166—Food Container	F. W. Stockton (B.A., University of Kansas)	$5,000 a year. Oct. 16, 1919.
167—Magnesia	M. S. Mason (M. S., University of Illinois)	$6,000 a year. Jan. 1, 1920.
	R. H. Heilman, assistant (University of Pittsburgh)	
166—Yeast	Ruth Glasgow (M.S., University of Illinois), senior fellow	$15,000 a year. Nov. 1, 1919.
	Grace Glasgow (M.S., University of Illinois). G. S. Bratton (B.A., University of Tennessee). F. M. Hildebrandt (Ph.D., Johns Hopkins University). W. H. Randall, assistant (George Washington University).	
169—Copper	G. A. Bragg (B.S., University of Kansas), senior fellow	$6,000 a year. Nov. 1, 1919.
	J. W. Schwab (B.S., University of Kansas).	
170—Household Utilities	F. F. Rupert (Ph.D., Massachusetts Institute of Technology)	$5,000 a year. Nov. 1, 1919.
	E. R. Edson (B.A., Clark College).	
171—Asbestos	A. F. Shupp (Ph.D., University of Pittsburgh)	$3,500 a year. Nov. 1, 1919.
172—Silicate	M. G. Babcock (M.S., Iowa State College)	$2,500 a year. Dec. 1, 1919.
173—Fiber	J. D. Malcolmson (B.S., University of Kansas)	$3,000 a year. Nov. 15, 1919.
174—Glycerine	R. K. Brodie (M.S., University of Chicago)	$5,000 a year. Nov. 15, 1919.
	Melvin DeGroote (B.Ch.E., Ohio State University)	
175—Light Metals	P. V. Faragher (Ph.D., Massachusetts Institute of Technology)	$4,000 a year. Dec. 1, 1919.
176—Fuel	J. G. Davidson (Ph.D., Columbia University)	$5,000 a year. Jan. 1, 1920.
177—Toilet Articles	(Fellow to be appointed)	$3,500 a year.
178—Silverware	H. E. Peck (B.S., Clarkson Memorial College of Technology)	$2,500 a year. Dec. 11, 1919.
179—Organic Solvents	L. M. Liddle (Ph.D., Yale University), senior fellow. H. W. Greider (M.S., University of Kansas)	$5,600 a year. Jan. 1, 1920.
180—Keratin	B. A. Stagner (Ph.D., University of Chicago)	$4,000 a yr. Jan. 1, 1920. Bonus: $5,000.
181—Synthetic Resins	(Senior fellow to be appointed). A. E. Coxe (B.S., University of Chicago)	$5,000 a year. Dec. 23, 1921.
182—Byproducts Recovery	Walther Riddle (Ph.D., University of Heidelberg). H. E. Gill, assistant (University of Pittsburgh)	$3,000 a year. Jan. 1, 1920.
183—A, Organic Synthesis	G. O. Curme, Jr. (Ph.D., University of Chicago), senior fellow. H. R. Curme (Ph.D., University of Pittsburgh). J. N. Compton (M.S., Columbia University). C. O. Young (Ph.D., University of Pittsburgh). E. W. Reid (M.S., University of Pittsburgh).	$32,400 a year. Jan. 1, 1920.
183—B, Organic Synthesis	H. A. Morton (Ph.D., University of Pittsburgh), senior fellow	
	C. J. Herrly (B.S., Pennsylvania State College)	
184—Coke	F. W. Sperr, Jr. (B.A., Ohio State University), advisory fellow	$7,020 a year. Jan. 1, 1920.
	O. O. Malleis (M.S., University of Kansas)	
	L. R. Office (B.S., Ohio State University).	
	H. S. Davis (Ph.D., Harvard University).	
185—Insecticides	O. F. Hedenburg (Ph.D., University of Chicago)	$3,500 a year. Jan. 1, 1920.
186—Fertilizer	H. H. Meyers (B.S., University of Pennsylvania)	$4,000 a yr. Jan. 5, 1920. Bonus: $5,000.
187—Glue	R. H. Bogue (M.S., Massachusetts Agricultural College)	$2,500 a year. Jan. 5, 1920.
188—Distillation	David Drogin (M.S., University of Pittsburgh)	$3,000 a year. Jan. 18, 1920.
189—Laundry	H. G. Elledge (M.S., University of Pittsburgh)	$5,000 a year. Feb. 15, 1920.
	Alice L. Wakefield, assistant (B.S., Margaret Morrison).	
190—Bread	H. A. Kohman (Ph.D., University of Kansas), senior fellow	$10.000 a year March 1, 1921.
	Roy Irvin (M.S., University of Kansas)	Bonus: $10,000.
	R. J. Cross (B.A., Leland Stanford Jr. University).	
191—Fruit Beverages	H. A. Noyes (M.S., Massachusetts Agricultural College)	$3,000 a year. March 1, 1920.

fellow and the directors are granted open access to the donor's factory and the co-operation of its operating staff. Reports on the findings of the research can be published with the consent of the company at any time or after three years from the completion of the fellowship work by permission of the director upon the decision that such publicity would not unduly injure the interests of the donor.

The Institute in its relation to a fellowship has two important functions. It brings into association a body of men having a wide variety of knowledge in pure and applied science and furnishes them with extraordinary facilities for augmenting and applying the same. While interconsulting among the fellows is largely done through the directing staff, free direct intercourse on scientific matters is permitted. The potency of this aggregation of specialists increases with the number of fellowships and the variety of industries represented by them. At the conclusion of a research, the donor of a fellowship often will have available the services of a man of training superior to that obtainable in the university or technical school and immediately adaptable to his particular requirements. The Institute is producing industrial specialists of its fellows, in the increased ability of whom the community will eventually be more benefited than by the most successful conclusion of any of their researches.

Industrial Fellowships

Industrial fellowships are usually founded by individual companies, but there are at present nine important association fellowships. These are shown in Table III. It is the intention of the administration to encourage this class of donors, because the benefits derived from their type of investigations will normally have the widest distribution.

Where the research involves more work than can be performed by one fellow, a sufficient staff, known as a multiple fellowship, is appointed, responsible through a senior fellow to the administration.

ADMINISTRATION
H. S. Coleman W. A. Hamor E. W. Tillotson
R. F. Bacon E. R. Weidlein D. S. Pratt

A very brief description showing the accomplishments of six of the association fellowships and four of the company fellowship investigations will now be given as affording examples of the work done at the Institute.

Laboratories[4], outside unit plants and experimental equipment will not be described further than can be done by the accompanying selection of illustrations.

Bread Fellowship

During the pioneer days of the industrial fellowship system at the University of Kansas, Dr. Henry A. Kohman isolated and grew a pure culture of spores concerned in the fermentation of "salt-risin" bread. This was very noteworthy, as it was the first scientific contribution of importance to the ferment bread-leavening industry. Since the introduction of these spores, "salt-risin" bread has been steadily increasing in commercial importance. Less than ½ per cent of the weight of the bread stock is lost in this spore-leavening process, which, when compared to the 5 per cent loss in ordinary yeast leavening, will be readily acknowledged by any one acquainted with baking finances to be of vast economic importance. While nothing has been accomplished toward elucidating the enzyme action of the spore, its products have been found to be mainly edible organic acids, such as lactic, and gases consisting of one-third carbon dioxide and two-thirds hydrogen. Dr. Kohman now markets these spores in quantity lots to the bakery trade.

In 1911, after reading Dr. Duncan's chapter on "Bread" in "Some Chemical Problems of Today," George S. Ward, of the Ward Baking Co., of New York, decided to establish a multiple fellowship and find out whether science could improve on the art of bread making as it had been passed on after the lifelong and collective efforts of hundreds of generations of bakers.

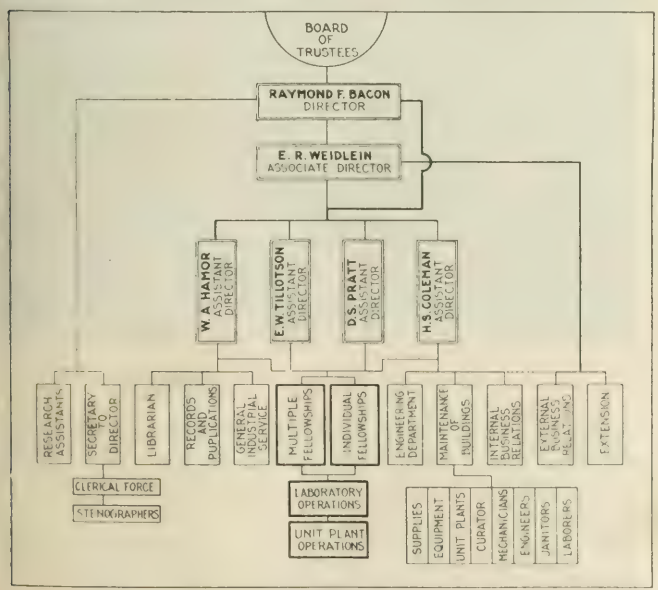
TABLE III. ASSOCIATION FELLOWSHIPS

	Companies	Foundation Sum
Leather belting	40	$4900
Refractories	84	7000
Canning	71	6000
Leather soling	60	3500
Magnesia products	4	6000
Asbestos	10	3500
Fiber board containers	20	3000
Insecticides	9	3500
Laundry	2500	5000



ADMINISTRATION CHART

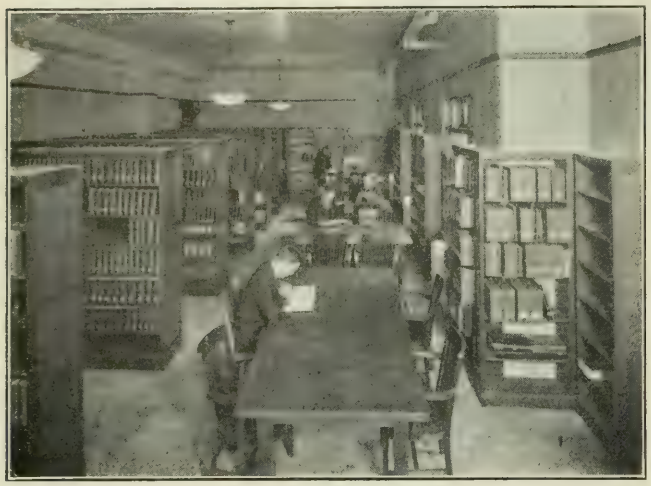
FELLOWS' ROOM

Dr. Kohman, already being the recognized genius in applying science to this industry, was chosen to take the fellowship.

Within a short time "Arkady" yeast food was evolved. In the old process of leavening, the yeast derived its nourishment mainly from the soluble sugar, mineral salts and protein contents of the dough. Considerable time appeared to be lost in the breaking down of the proteins by the yeast, so Dr. Kohman experimented with ammonium salts as a substitute for this complex source of nitrogen. The yeast thrived and generated the leavening carbon dioxide in a much more efficient manner. The brewing industry for generations had known that lime salts were an important tonic,

so Dr. Kohman studied their application and found that they were of great value. Hints taken from the chemical fertilizer industry did not prove so profitable, with the result that potash and soluble phosphates were found to contribute nothing. The wheat flour carried a sufficient content of these latter salts, while the others, though present, were in insufficient amounts adequately to supply the appetite of the yeast.

After Dr. Kohman had mastered the yeast-feeding problem, he found that it was possible to hasten the aging or maturing process. This was believed to be an



LIBRARY AND READING ROOM

oxidation phenomenon, wherein the leavened dough cell walls became more viscid and elastic. A small addition of potassium bromate was eventually found to give the desired oxidation necessary to the aging process. The most efficient mixture of salts so far determined has been found to be 100 g. of ammonium chloride, 240 g. of calcium sulphate and 3 g. of potassium bromate to the 200 kg. of flour used. The decrease in the amount of sugar lost in leavening fermentation is about 27.5 lb. per ton of flour. Only half as much yeast is required, so it can be said that the cost of leavening bread with yeast has been cut in two by the discovery and adoption of "Arkady" yeast food.

Laundryowners' National Association Fellowship

About one-half the laundry companies in the United States, representing a business of at least $150,000,000, through their Association, are the donors of the laundry multiple fellowship. Harvey G. Elledge, assisted by Miss Alice L. Wakefield, has given individual attention to numerous problems as they have arisen in the plants of the Association throughout the country. Poor textiles and dyes nearly always do not impressively come into evidence until they have been laundered. An accompanying photomicrograph, Fig. B, illustrates what to the unaided eye would pass for silk cloth. The large cotton filling threads and the few bushed out unspun silk fibers make a combination which is almost as delicate as a spider web. A shirt made of this material failed to survive intimate contact with soap and water even when carefully laundered by hand.

A fading dye does not give as serious trouble as a mixed blend, one important member of which is not fast. The owner of what was a blue shirt can rarely be made to be contented with the delivery of the same article washed out to some other color. More serious trouble arises when the fabric has been tendered in dyeing, for then the oxycellulose formed passes into the soapsuds emulsion along with the soiling materials. Fig. A represents a blue bandana handkerchief, having white dots, which were made by removing the dye by printing with stripping salts. Failure to wash out these corrosive salts promptly, if at all, permitted the formation of non-fibrous oxycellulose, and, when the handkerchief was laundered, the product looked as though it had received pretty rough treatment.

Such occurrences, becoming more and more common in these days of higher prices and lowered production, have given to the laundry fellowship the added purpose of educating the public to the necessity for discrimination in purchasing, which is the only method that can successfully eliminate the present condition of unfair prejudice against the power laundry. This purpose, in connection with the original object of investigation of the actual problems of conducting a power laundry in so far as they are related to chemistry, has opened a field which, when it has been fully developed, shall have increased the store of chemical and industrial information many-fold. One of the most useful of the recent accomplishments of the laundry fellowship has been the working out of standard washroom formulas. These scientific procedures are now in use in the laundries of the Association membership.

Refractories Manufacturers' Association Fellowship

Two and one-half years ago, the Refractories Manufacturers' Association founded a multiple fellowship at the Institute for the main purpose of developing standard tests to be used in the specifications of refractories. Simple tests that could be interpreted to or would directly indicate the properties of a refractory in actual use were very much desired. A fuller understanding of the purpose of the tests and a discontinuance of mis-

TYPICAL SMALL LABORATORY

application of them in many specifications of consumers were also sought. Incidentally, it was believed that improvements in refractory products would be a sequel to better methods of testing.

Raymond M. Howe and a staff of three are amply meeting the expectation of the donors of the fellowship. They have aided much in clearing up the variation of

AISLE OF LABORATORY SUPPLY ROOM

fusion with respect to time of heating and under loads. Slag penetration and abrasion, spalling and changes in volume under reheating are all being kept under consideration. At present the clay silicates form too complicated a system for their properties to be resolved to and conceived by a few fundamental physical laws. Whatever advance is made in this direction will first be associated with simpler materials such as magnesia and silica products. In the case of magnesia, extensive investigations have been required to develop a domestic product having the properties of that formerly imported. The effect of the basic fluxes such as lime, iron oxide, etc., on the slaking, slagging and general stability in use was sufficiently determined to give the data required for the production of satisfactory magnesia products from domestic magnesite.

The most outstanding among the industrial contributions of this fellowship is an improvement in manufacturing auger machine-made brick. While such firebrick find wide commercial application because of their uniformity and density, they are sometimes regarded with skepticism because of a more or less laminated structure. These laminations are the result of the center of the clay column moving faster than the exterior, due to the resistance caused by the surface of the die. It has been found that this lamination may be removed by repressing the soft unburned bricks on edge, thus overcoming the prejudice of the mason who has trouble in accurately breaking a laminated brick, retaining the economy of the process, and extending the application of such bricks to larger fields.

The Dental Products Fellowship

The Lee S. Smith & Son Manufacturing Co. was not satisfied with the opaque dental cements in general use up to 1915 and desired to manufacture a translucent tooth-like product, highly resistant to physical and chemical action. Dr. C. C. Vogt was chosen to work on that problem at the Institute. The non-translucent cements used prior to the completion of Dr. Vogt's work consisted of an opaque aggregate of metal oxides, such as zinc, etc., bonded together by insoluble translucent phosphate salts, formed by the reaction between the basic aggregate and phosphoric acid. Dr. Vogt's problem ultimately simmered down to producing a basic translucent aggregate. By fusing his metal oxide with fluxes such as feldspar, silica and fluorides, he was eventually able to get just such a translucent basic aggregate as he desired. Considerable investigating was required to select the best formulæ and to meet all the specifications. The nation-wide adoption of the cement by the dental profession within the last three years is ample testimony of the success of this fellowship.

Magnesia Association Fellowship

Reliable heat data on insulation materials, especially 85 per cent magnesia, are required to enable manufacturers to know what a given investment in insulation materials will net them on their fuel account. In 1918 Glen D. Bagley and R. H. Heilman held the fellowship, and during the present year M. S. Mason and Mr. Heilman have proceeded with the investigation.

The method of procedure is to measure the electrical energy input required to maintain a given temperature difference between the test pipe and the air in the room. The pipe is heated by means of three separate electric heating coils which are arranged end to end within the pipe. When the thermocouples in the pipe wall indicate that the center and the end sections are at the same temperature, there is no longitudinal flow of heat within the pipe. Under such conditions the energy supplied to the center section of the pipe must flow radially through the covering of the center section and be lost by radiation and convection. From the heat equivalent of the electrical energy supplied to the center section, the loss per unit area of pipe surface can be calculated. The investigation will be continued to find how these losses are affected by variations in covering and ranges in temperature upon exposure under all possible factory conditions. Excellent sets of curves showing heat losses, steam costs and economical sizes of magnesia insulation have been put out by the association under whose auspices the research work is being carried out.

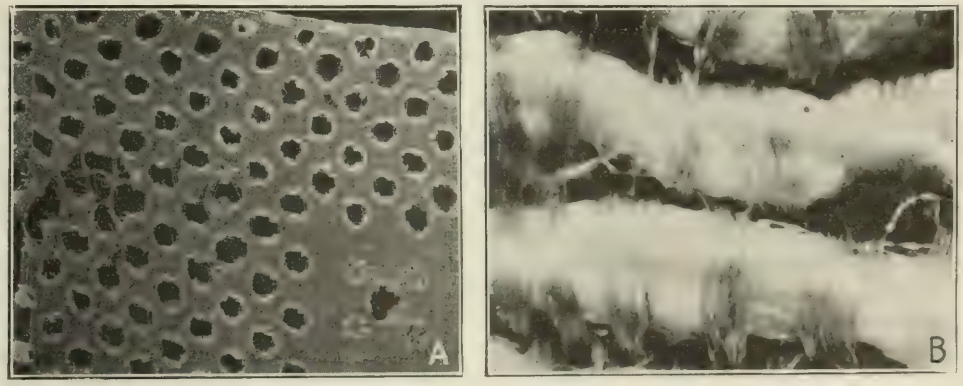


FIG. A. COTTON TENDERED WITH STRIPPING SALTS. FIG. B. UNIQUE COTTON-SILK WEAVE

The Rex Insecticide Fellowship

A number of arsenates and arsenites have been manufactured by various companies for insecticidal purposes, but the arsenates of lead and of calcium have proved to be the best. The former may be used on all

kinds of foliage, but the latter should not be used on stone fruits, although it may be used on other foliage, and especially in combination with lime-sulphur solution.

The Rex Spray Companies, desiring to improve their products and to manufacture other insecticides, became the donors of this fellowship. Dr. Oscar F. Hedenburg, industrial fellow, has made considerable progress with their problems during the past two years.

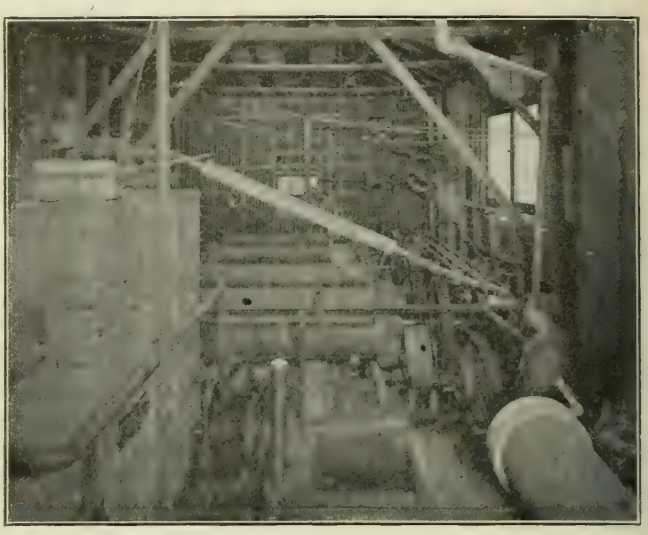
Arsenate of lead has been in use for a number of years. All brands are guaranteed to contain 30 or 31 per cent of arsenic oxide, As_2O_3, and may contain up to 32 per cent. Arsenate of lead must not contain more than 1 per cent of soluble arsenic, calculated as As_2O_5.

Since nearly all arsenate of lead is used in suspension in water, that product which remained in suspension the longest time, or which settled the most slowly, has been regarded the most satisfactory. Besides this property, adhesion to the foliage and spreading or covering power have been considered of great value.

As a result of work in connection with this fellowship, an arsenate of lead has been produced which exhibits to an unusual degree the properties mentioned above. It has been named "NuRexform" dry arsenate of lead. From suspension in water it separates only after standing several hours. It is so finely divided that the agitated suspension has a "silky" appearance. When sprayed onto a surface, it covers it uniformly, and, after the water has evaporated, the dry deposit cannot be washed off by a heavy flow of water. Even when a sulphide solution, such as lime-sulphur solution, is added to the suspension, this arsenate of lead darkens very little and the stability of the suspension is hardly affected. Other arsenates of lead, when treated thus, become flocculated and almost black, and as a result the property of suspension is lost. As applications for patents have only recently been filed, a more detailed account cannot be given at present.

The destructiveness of the cotton boll weevil made extensive research of effective control necessary. This work was carried on by the Government at the Delta Laboratory, Tallulah, La. Dusting cotton plants with calcium arsenate five times during the season was found to give the most effective control. An important demand for calcium arsenate was created without giving the various producers much advance notice.

UNIT PLANTS



UNIT PLANT—TUBE MILL INSTALLATION

Dr. B. R. Coad, in charge of the work, set the following requirements for calcium arsenate to be used in boll weevil control:

Not less than 40 per cent As_2O_5.
Not more than $\frac{3}{4}$ per cent soluble As_2O_5.
Density, 17 to 22 lb. per cu.ft.
80 to 100 cu.in. per lb.

The legal limit for soluble arsenic oxide is 1 per cent. The soluble arsenic value measures the tendency of an arsenate to destroy the plant tissue.

Research on this fellowship has made it possible to produce a fine, white calcium arsenate containing less than $\frac{1}{2}$ per cent of soluble arsenic, and some batches have shown only a trace of soluble arsenic.

Production of calcium arsenate containing soluble arsenic below the legal limit has been the greatest difficulty experienced by manufacturers. The manufacture of calcium arsenate with soluble arsenic far below the legal limit is a distinctive advance.

The Protected Metals Fellowship

A prominent manufacturer of a sheet steel building material which is coated with rust-proofing layers of asphalt and asbestos felt experienced great difficulty in preventing the coated sheets from sticking together, especially when they were subjected to any considerable pressure. On this account, the material could not be piled either during storage or shipment, without taking considerable risks.

Dr. J. H. Young found the solution of the problem within thirty days after the inception of the work. He obtained from cellulose an economical surfacing material, which adhered well to the asphalt coating as well as giving the desired break in contact between the asphalt surfaces.

The Container Club Fellowship

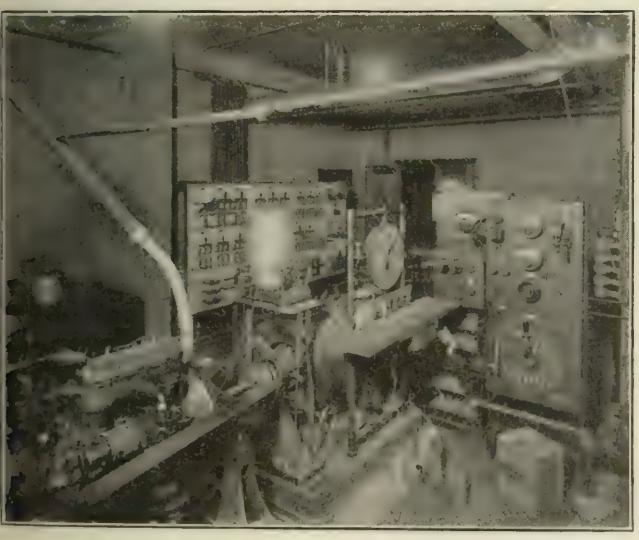
The recent advent of the Webb paper and box tester was due to the unreliability of the Mullen test on corrugated fiber board. The manufacturers experienced great difficulty with the railway testing laboratories on this account. J. D. Malcolmson has spent the last year in perfecting the Webb instrument with its various attachments. A small perforated foot fitting the corrugation is so arranged that perfect support is given to the fiber, the true breaking strength of which is then measured by the perforating force of the plunger. Each wall is measured separately and the strength of the

board is arbitrarily taken as the sum of the walls. Many of the instruments are now in operation and specifications are being drawn calling for its use. The tester is so calibrated that it gives Mullen figures on paper. A tensile strength attachment is provided so that the test figures of the Schopper instrument can also be obtained with it. A small pocket tester has also been perfected, which is intended for the use of inspectors in catching shipments that are suspected of being under specifications.

The adhesives and other raw materials used in the manufacture of boxes from the corrugated board have been considerably improved. The viscosity of waterglass has been found to rise enormously with the addition of sodium chloride. This is important in reducing the alkalinity and amount applied to obtain adhesion. Recommendations have been made to have the heavy fibers of the boards belted crosswise so as to give a maximum lateral strength. Up to the present ordinary tape has been used in strapping the boxes. This has the stronger cords running lengthwise and is designed to give high tensile strength. Resistance to lateral tears is required of box tape, so a special weave has been worked out that should prove more satisfactory than the tape now in use.

Copper Flotation Fellowship

The Institute has been studying the subject of flotation for about six years. In the beginning a great deal of attention was devoted to the theory of the froth process which was then in a very confused state. As



MOTOR FUEL POWER TESTING EQUIPMENT

one result of this investigation into the mechanism of the process, the great effectiveness of alphanaphthylamine and a few closely related compounds as flotation agents for the sulphide copper in the low grade disseminated ores of the Southwest was discovered by the late Dr. H. P. Corliss. In the opinion of J. M. Callow, perhaps the foremost authority on flotation in this country, this discovery marked the greatest single improvement in the art since its introduction into the United States.

The discovery of alphanaphthylamine also opened up a whole new field for research. Recently the work of the fellowship, carried on by C. L. Perkins and R. E. Sayre, has been largely confined to the study of this field, with results which will one day constitute a very interesting chapter in the story of the development of the flotation process.

The Leather Belting Fellowship

The Leather Belting fellowship was founded for the purpose of investigating the comparative power-carrying capacities of leather and substitute belts and to obtain definite scientific data in reference to the transmission of power by belts. For this work a complete belt testing outfit, consisting of two 100-hp. Sprague electric dynamometers, was installed at the Institute. One of these machines is arranged to operate as a motor and the other as a generator. These machines operate on 220 volts d.c. and are so connected that the output of the generator is pumped back into the line, thus making it necessary to draw on the outside source of power only to the extent of making good the losses in the machines. The fields of both machines are mounted on ball bearings to permit them to turn freely about the armature axis. The torque of the fields is indicated on dial balances through a system of levers. The dials and lever systems are so arranged that the dial reading multiplied by the r.p.m. divided by 1000 equals the horsepower. Connected to each armature shaft is a revolution counter and by the manipulation of a single switch both are either started or stopped through the medium of a magnetic clutch. By this arrangement it is possible to measure the slip of a belt to an accuracy of $\frac{1}{10}$ of 1 per cent. Since April, P. G. McVetty has been testing out all types of belting material.

Principles Applied in the Administration of All Fellowships

The principles applied in the administration of the investigational activities of the Mellon Institute of Industrial Research are much the same as those followed in any other effective business. It is general experience of mankind that if it is wished to get any work well done, the way to go about it is to select competent men, extend them the largest liberties compatible with order and hold them responsible for the attainment of the desired results.

To illustrate: The industrial fellowships of the Mellon Institute are placed in charge of research chemists and engineers selected solely by reason of their special fitness for the conduct of the investigatory work concerned, and these men are accorded the privilege of being the autocrats of their own destinies within the limits of the foundation sums of their industrial fellowships. In addition, every industrial fellow receives the constant advice and collaborative support of an administrative staff which is constituted of experts in scientific research. As stated by the Carnegie Institution of Washington, whose departments of research are similarly operated, the principle applied to the incumbents of all industrial fellowships is "autonomous freedom and reciprocal accountability."

No attempt has been made to offer the reader data on which to base a comparative opinion on research as commonly performed in company laboratories and under the fellowship system as cited above. The former does not lend itself readily to brief treatment because of its extreme variation in ways, means and results. However, from such information as has been made generally known concerning isolated plant and laboratory research work, it may be stated with confidence that the fellowship system is more certain, economical and speedy in attaining results.

Classifying Organic Compounds by the Prager-Jacobson System

By Donald W. MacArdle

OF THE various methods which have been proposed for the classification of organic compounds, only one, that of Richter, assigns to each compound a place determined solely by its formula. In the Richter system, the ultimate elementary composition of the substance is the criterion; this lays the system open to the grave objection that similar compounds, as ethane and propane, are in different sections, while such dissimilar compounds as allyl alcohol, propionic aldehyde, and acetone are grouped together because their empirical formulas are the same, C_3H_6O. To provide a system which shall avoid this defect, but which shall be sufficiently comprehensive to include all known organic compounds, Prager and Jacobson, the chief editors of the fourth edition of Beilstein's Handbook, have developed a method differing in many points from any heretofore proposed. The fundamental rules of this system form the introduction to the first volume of the Handbook, on which the present article is based.

Main Divisions

If we assume that in a compound all atoms or radicals, other than hydrogen atoms, directly attached to carbon, except such as form cyclic complexes, are replaced by an equivalent number of hydrogen atoms, we obtain the "stem nucleus" of the compound. Thus the stem nucleus of (1) aminochloracetic acid ($NH_2CHCl.COOH$) is ethane (CH_3CH_3); (2) of picric acid [$C_6H_2(NO_2)_3OH$] is benzene (C_6H_6); (3) of furfuraldehyde ($C_4H_3O.CHO$) is methyl furane ($C_4H_3O.CH_3$); (4) of methyl ethyl ether ($CH_3CH_2.O.CH_3$) is $C_4H_8 + CH_4$, etc. The stem nuclei are the first consideration in the systematic arrangement of compounds, and are divided into three groups; (I) Acyclic stem nuclei, in which the carbon atoms are united entirely in chain arrangement (examples 1 and 4 above); (II) isocyclic stem nuclei, in which carbon atoms are united in ring formation, and which have only carbon atoms for ring components (example 2); (III) heterocyclic stem nuclei, in which carbon atoms are united in ring formation not only to other carbon atoms, but also to polyvalent atoms of other elements; in this group would fall not only compounds like example 3, but such cyclic compounds as succinic anhydride, phthalimid, lactones, etc.

To these three main divisions of the system, acyclic, isocyclic and heterocyclic, a fourth division is added to include naturally-occurring organic products of incompletely known structure, such as rubber, starch, chlorophyll, etc., or complex mixtures like petroleum.

Principle of Latest Position in the System

If a compound has stem nuclei belonging to two or more main divisions, as, for example, phenyl ethyl ether ($C_6H_5.O.C_2H_5$), whose stem nuclei are C_6H_6 and C_2H_6, the compound falls in the same main division as the one of its component stem nuclei which in the system comes last. Accordingly, phenyl ethyl ether would be treated not with ethyl compounds in the first main division, but with phenyl compounds in the second. This "principle of latest position in the system" applies throughout for all such cases which arise not only in assignment to main divisions, but in further classification into classes, sub-classes, rubrics, etc.

In the case of heterocyclic compounds a complication arises not met with among acyclic or isocyclic compounds, due to the presence in the stem nuclei of atoms other than carbon and hydrogen. This makes necessary an arrangement of these compounds into "heteroclasses," according to the kind and number of the heteroatoms (that is, the atoms in the ring other than carbon atoms). Compounds containing one or more oxygen atoms are treated first, then those with nitrogen heteroatoms, and finally heterocompounds containing both oxygen and nitrogen. In all cases arising throughout the system, derivatives of sulphur and selenium are grouped, whenever possible, with the corresponding oxygen derivatives; thus mercaptans follow alcohols directly, and thiophenes follow furanes. Sulphonic and selenic acids have, of course, no corresponding oxygen derivatives; their place in the system will be shown presently.

Formation of Classes Within the Main Divisions

Alteration of the stem nuclei may take place by the replacement of one or more of the hydrogens attached to the carbon atoms by "inorganic" atoms or radicals (by "inorganic" is meant elements other than carbon and hydrogen). The most important of these inorganic elements are fluorine, chlorine, bromine, iodine, oxygen, sulphur and nitrogen. The halogens appear almost always as single atoms replacing a single hydrogen, but atoms of the three latter elements, by combination with each other and with hydrogen, give rise to a very considerable number of substituent radicals, such as OH, SH, SO_3H, NH_2, NO, NO_2, $NH.NH_2$, N_3, etc. It will be noticed that certain of these radicals contain one or more hydrogen atoms; these hydrogens may in turn be replaced by other atoms or groups, and thereby the number of derivatives greatly increased. These radicals containing hydrogen atoms are known as *functioning substituents*. Seven of the substituents, however—F, Cl, Br, I, NO, NO_2, N_3—do not contain hydrogen and so cannot undergo further substitution. For this reason they are called *non-functioning substituents*. Compounds containing non-functioning groups are considered substitution products of the compounds in which the non-functioning groups are replaced by hydrogen (or hydroxyl—see below); $NO_2CH_2CH_3$ is derived directly from CH_3CH_3; $ClCH_2CH_2OH$ from CH_3CH_2OH, etc., and these substitution products are included in the same class as the parent substance.

Rôle of Functioning Substituents

The functioning substituents, on the other hand, furnish the basis for the establishment of classes within the main divisions. The group -OH, for example, characterizes the class of hydroxy-compounds (alcohols and phenols); the group $-NH_2$ the class of amines. These classes are in turn divided into sub-classes according to whether the characteristic group appears in the molecule once or several times, whether as the sole functioning group or in conjunction with other dissimilar groups.

In the division of hydroxy-compounds it will be noted that when several hydroxy-groups are present, there are two distinct possibilities of arrangement. The hydroxyl groups may be attached to different carbons,

as in ethylene glycol ($CH_2OH.CH_2OH$) and pyrogallol [$C_6H_3(OH)_3$], or they may be attached to the same carbon, as in the compounds $RCH(OH)_2$, $RR'C(OH)_2$, $RC(OH)_3$. Compounds of this type are highly unstable, but by the splitting off of water they yield the aldehydes, ketones, and carboxylic acids, RCHO, RR'CO, RCOOH, compounds of great importance. It would be obviously unsuitable to consider these groups of compounds as polybasic alcohols; instead the groups =CO and -COOH are included in the list of functioning substituents which determine classes, forming respectively the carbonyl derivatives and the carboxylic acids.

Compounds which have a functioning group and one or two other functioning or non-functioning groups attached to the same carbon atom are considered derivatives of the carbonyl-compound or carboxylic acid which results from the replacement of these substituents by hydroxyl, with subsequent splitting off of water. Thus $CH_3CH(NH_2)(Cl)$ is a derivative of CH_3CHO, and $CH_3C(NH_2)(Cl)_2$ of CH_3COOH. The same rule is followed in the case of nitrogen bound by two or three valences to carbon: e.g., $CH_2CH{:}NH$ is a derivative of CH_3CHO; $CH_3C \vdots N$ is a derivative of CH_3COOH. However, when two or three non-functioning groups are attached to the same carbon without at the same time a functioning group being attached, this rule does not apply. For example, CH_2Cl_2 is a derivative of methane rather than of formaldehyde; $CH_3CBr_2(NO_2)$ is a derivative of ethane rather than of acetic acid.

Following these rules, and in particular the "principle of latest position in the system" mentioned above, the main divisions are divided into classes according to the functioning group present. In the complete system there are twenty-eight classes, as follows: (1) Stem nuclei; (2) hydroxy derivatives; (3) carbonyl derivatives; (4) carboxylic acids; (5-7) acids of sulphur and selenium; (8-22) nitrogen derivatives, such as amines, hydroxylamines, azo compounds, etc.; (23-28) compounds with direct bonding of carbon to polyvalent inorganic elements, as phosphine, cacodyl, etc.

Division of the Classes Into Sub-Classes

In the first and second main divisions and in each heteroclass, the first class is that of stem nuclei (in the acyclic and isocyclic divisions these are the hydrocarbons). These stem nuclei are divided into sub-classes (homologous series) arranged according to decreasing saturation; the homologous series are in turn divided into rubrics arranged in order of increasing number of carbon atoms. The series C_nH_{2n+2} would have the rubrics CH_4, C_2H_6, C_3H_8, etc.; under the rubrics the individual isomers are taken up. The arrangement of the isomers is based on a few simple rules, for the discussion of which space is not available here.

With the second class begins the series of classes characterized by functioning groups; the sub-classes are here determined by the number of functioning groups present. Thus the sub-classes of this group would be monohydroxy derivatives, dihydroxy derivatives, trihydroxy derivatives, etc. Each sub-class is in turn divided into homologous series, and these into rubrics, as in the case of the stem nuclei.

In the third class a further complication is introduced: The combination of the characteristic functioning group of the class with the functioning groups of previous classes; in addition to simple carbonyl compounds we must consider in the third group compounds containing both =CO and -OH. Such compounds with mixed functions are always included after all the compounds containing only the single type of functioning group (with, of course, their non-functioning derivatives). In the fourth class the sub-classes would be monocarboxylic acids, dicarboxylic acids, etc., hydroxycarboxylic acids (these and the following sub-classes are arranged in the order of increasing number of oxygen atoms), carbonyl-carboxylic acids, and hydroxy-carbonyl-carboxylic acids; the sub-classes are divided as before.

Index Compounds and Their Derivatives

In the division of the classes into sub-classes, homologous series, etc., we come finally to the individual compounds which are the true representatives of the class. These are known as "index compounds," and are followed directly by such of their derivatives as are not, according to the rules previously stated, considered as index compounds to be treated elsewhere. The derivatives are of three types: (1) Functional derivatives, resulting from the alteration of the functioning group; (2) substitution products of the stem nucleus or functioning group by non-functioning substituents; (3) derivatives resulting from the replacement of functioning oxygen by sulphur or selenium.

The arrangement of derivatives of the second type (substitution products) is according to the following order of substituents: F, Cl, Br, I, NO, NO_2, N_2. For each index compound derivatives containing fluorine alone come first, then that with one chlorine atom (with fluorine derivatives), with two chlorine atoms (with fluorine derivatives), etc. This procedure may be briefly expressed in the rule: "First combination of the new substituent with all that precedes it, then multiplication of the new substituent, with combinations as before."

Derivatives of the first type (functional derivatives) are considered as being formed by "anhydrosynthesis"; that is, by coupling of the functioning group (if carbonyl or carboxyl, in the hydrated form) with organic compounds containing hydroxyl attached to carbon, or with inorganic hydrogen-containing compounds, the coupling taking place with the splitting out of water. The component reacting with the index compound is known as the coupling compound. Such an alteration of the functioning group of the index compound is known as an *alteration of the first degree.* If the coupling compound is capable of undergoing similar substitution, alterations of the second, third, and higher degrees are possible. In the arrangement of derivatives of an index compound, if the first degree is considered higher than the second, the second higher than the third, etc., the rule may be stated that a new derivative of a higher degree is taken up only after all the lower degree derivatives of the preceding compound of the same degree have been included.

If a functioning group can undergo simultaneously more than one first degree alteration, as in the amino group, with two replaceable hydrogens, or the hydrated carboxyl group [$-C(OH)_3$], the same rule for arrangement in the system is followed as in the case of substitution products: First combine, then multiply.

In the case of a compound with two functioning groups, if the groups are the same, a first degree alteration is made in one group (the order of the sub-

stituents being the same as the order in the series of compounds with hydroxyl attached to carbon), all derivatives of this given; then the same substitution made in the other group, all alterations of the first group given, etc. If the groups are different, the one standing earlier in the list of functioning groups is caused to undergo all possible substitutions, the other group remaining unchanged; then a first degree alteration of the second group is made, and the complete series of substitutions of this compound given, and so on.

For a full explanation of how a given complex compound is located in this system, reference must be made to the complete exposition of the system in the Handbook. Suffice here to say that the method used is the reverse of the anhydrosynthesis; the compound is considered as being resolved into its component index compounds (or their substitution products) by hydrolytic splitting, and by the constantly-used "principle of latest position in the system" the compound is located under one of its hydrolysis products.

Space is also lacking here for a summary of the rules for the arrangement in the system of compounds of easily altered structure (tautomeric substances, pseudo-acids and pseudo-bases, etc.), of diphenylmethane and triphenylmethane dyestuffs, and of a few other less important types.

In a work like Beilstein, which in the fourth edition includes more than 150,000 compounds, the system of arrangement must of necessity be complex and subject to a considerable number of more or less arbitrary rules; for a person who makes frequent reference to the Handbook no summary of the system of arrangement can take the place of a careful study of the introduction to vol. 1 (pp. 1-46), in which the system is explained in detail, with numerous examples to clear up obscure points; if the present article assists in the understanding of the introduction, or serves as a passable substitute to occasional users of the Handbook, its purpose will have been accomplished.

Organic Compounds of Uncertain Structure Found in Nature 4720—4877

The division of the Isocyclic Compounds into Classes and Sub-Classes is the same as of the Acyclic Compounds. The numbers under each Class indicate the sections included therein. The whole work is divided into 4877 sections and will appear in fifteen volumes. The first volume includes sections 1—151.

Woody Structures of Fractures of Tranverse Test-Pieces Taken From Certain Special Steels*

Observations Seem to Indicate That Acid Open-Hearth Metal Is Less Liable to Give Woody Fractures, While Molybdenum and High-Carbon Nickel Steel Give Poor Transverse Tests by Virtue of Their Chemical Composition

By J. J. COHADE†

IT IS sometimes found in transverse tensile tests that the elastic limit and the breaking strain are practically the same or only slightly lower than n the longitudinal direction of the piece. On the ther hand, contraction and elongation are lower. mpact test bars withstand a smaller number of blows; otched bars withstand, section for section, fewer ilogrammeters, and the bent layers break at a lower ngle. At the same time, the fracture-surfaces are treaked with parallel lines resulting from the intersec- ion of that surface with surfaces parallel with the axis iven to the structure of the metal during forging. For his reason such fractures are described as "woody ractures."[1]

Origin of These Streaks

These streaks may result:

1. Mostly from the presence of non-metallic inclu- ions.
2. Much less frequently from numerous tiny blow- oles.
3. From the chemical composition of the metal.
4. From overworking.

We will leave aside the influence of working, which as been very minutely and very completely dealt with y Mr. Charpy.[2] If exception be made of the second ause enumerated above, the three other causes inter- ene simultaneously in all steels and make it difficult o separate the particular influence of each on the esults.

Presence of Non-Metallic Inclusions

The author will not dwell on the formation of non- netallic inclusions in steels, which has been explained y many metallurgists, and, more especially and with nuch care, by Dr. McCance.[3] The influence of such nclusions on defective transverse results, and there- ore on woody fractures, cannot be doubted. There is ometimes found, during the manufacture of gun steel arried out with every precaution and yielding very xcellent results, an occasional cast of normal composi- ion giving poor results and woody fractures. If these e examined under a magnifying glass there will enerally be seen more or less greenish inclusion stains, longated in the direction of the streaks. In cases here a simple examination with a lens does not suffice, microscopic examination of a small sample of the netal, after polishing and slightly etching, will reveal bnormal amounts of non-metallic inclusions. There will be seen on the surfaces of tensile test-pieces which have given these defective results, slight cracks or, at least, faint depressions. If the bar be broken carefully, by bending, at these points, inclusions will be found.

The formation of streaks in fractures, owing to the influence of inclusions, is easily explained. The original globules, more or less ovoid in form, become flattened and elongated parallel with the direction of the flow of the metal during forging. When the steel is subjected to a tensile stress perpendicular to this direction, it cannot elongate at the points at which these inclusions are found, for at these points fracture has already taken place. What occurs is as though the bar had a series of internal parallel notches preventing the elongation of the neighboring metal and fracture takes place suddenly, passing from one notch to the next and producing the typical stepped fracture which is described as "woody" and which characterizes these steels.

Presence of Numerous Tiny Blowholes

Tiny blowholes which have not been welded up during forging will similarly form planes of separation parallel with the direction of the working of the metal and play exactly the same part as inclusions.

Chemical Compositions of the Metal— Molybdenum Steels

The author was much struck in 1894 with the influence which the chemical composition of the metal might exercise on the defective results of transverse tests with woody fractures.

A series of molybdenum steels were studied in the form of small ingots cast from crucibles. The results having been very satisfactory, it was decided to run some charges in a 10-ton basic open-hearth furnace in order to ascertain what difficulties their furnace manufacture might present and to cast ingots of sufficient size to investigate their different possible applications.

One of these casts (No. 930) had the following composition:

	Per Cent		Per Cent
Carbon	0.360	Phosphorus	0.016
Silicon	0.041	Manganese	0.420
Sulphur	0.017	Molybdenum	0.470

The metal was therefore very pure and was prepared with great care.

One of the ingots was made into a gun tube. All the tensile test-pieces cut transversely gave low contractions and elongations, and woody fractures. The first impulse was to attribute this lack of success solely to the presence of oxides, or other non-metallic inclusions, inevitable when working by basic open-hearth.

It was possible, however, that the molybdenum itself

*A paper presented before the 1919 autumn meeting of the ron and Steel Institute, (British).

[3] *J. Iron and Steel Inst.*, 1918, No. 1, p. 239. See also H. Styri, Chem. & Met. Eng., vol. 20, p. 342.

might intervene, and to clear up this question the laboratory experiments were resumed. Two small ingots of 10 kg. each were made in the crucible, one with molybdenum and the other without. Their composition was as follows:

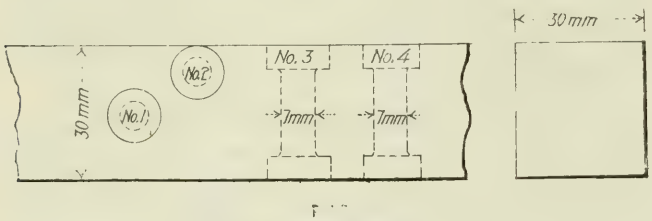
	With Molybdenum per Cent	Without Molybdenum per Cent
Carbon	0.300	0.450
Silicon	0.170	0.190
Sulphur	0.016	0.020
Phosphorus	0.029	0.026
Manganese	0.120	0.420
Molybdenum	0.530	nil

These small ingots, which were square in section (80 x 80 mm.) were transformed, by forging, into square bars 30 x 30 mm., and annealed at 900 deg. and cooled in air.

After cropping 4 per cent from the bottoms a piece 260 mm. long was cut longitudinally from each and two test-bars 13.8 mm. in diameter and 100 mm. long between punch marks were machined from them. They gave the following results:

	Elastic Limit per Sq.mm. Kg.	Tensile Strength per Sq.mm. Kg.	Elongation per Cent
With molybdenum	57.3	71.6	16.3
Without molybdenum	37.2	65.5	19.0

A length of 150 mm. was cut from the continuation of the bars which furnished the above test-pieces, quenched in water from 900 deg. C., and annealed at



LOCATION OF TEST-BARS

600 deg. C. Small transverse bars were also taken, as shown in the sketch (Fig. 1). Nos. 1 and 3 were at right angles to each other and followed the axis of the bar; Nos. 2 and 4 were similarly at right angles to each other and cut in such a manner that their heads were tangential to the side surfaces. The results of the tensile tests are given in Table I.

TABLE I. TESTS ON MOLYBDENUM STEEL

Description of the Bars		Tensile Strength Kilograms per Sq. mm.	Appearance of the Fractures.
Molybdenum steel	No. 1	96.6	Fine lines; low contraction
	No. 2	105.7	Lines hardly visible; fairly good contraction
	No. 3	94.0	Fine lines; low contraction
	No. 4	106.0	Lines hardly visible; fairly good contraction
Steel without molybdenum	No. 1	90.5	No lines, good contraction
	No. 2	92.3	No lines, good contraction
	No. 3	89.3	No lines, good contraction
	No. 4	91.9	No lines, good contraction

The elongation, owing to the dimensions of these bars, being meaningless, has not been given.

It will be seen that the ordinary steel gave no streaks, whereas all the molybdenum steel bars presented them. They are barely appreciable in the bars cut from the edges, although they actually exist; they are much more marked in the bars cut along the axis. The dimensions of the ingots being very small and the test-pieces having been cut from the portion corresponding with one-third of the ingot, it was hardly probable that the difference between the results was due to segregation; it might rather be attributed either to the differences in crystallization—needle-shaped along the edges, equiaxial in the center portion—or simply to some slight porosity of the latter. It will be noted later that microscopic examination of these small samples showed that the metal was practically free from inclusions.

It would therefore appear highly probable that molybdenum, even in small quantities, intervenes to accentuate the bad results of transverse tests.

Attempted Improvement of Molybdenum Steel

These tests can be grouped into three categories:

1. Modification of the structure of the ingot by more rapid cooling.
2. Modification of the structure by forging at a higher temperature.
3. Modification, after forging, by reheating and quenching.

First Group

Two small molybdenum steel ingots, of the same dimensions and practically of the same composition as the foregoing, were cast, after melting in crucibles, one in the ordinary way and one into an ingot mold plunged into water. The transverse fracture of these two ingots within 40 per cent of the bottom was very sound; that of the ingot cast into the water-cooled mold revealed bacillus-like crystallization going right through to the center, whereas in the other ingot this structure only occupied a superficial zone about 15 mm. thick. After forging the portions representing the 40 per cent lower ends of the ingots, a length of 150 mm. was cut from the bar, and this piece was quenched, annealed and transverse test-bars cut from it as previously described. The fractures of the pieces along the edges showed very fine, barely perceptible lines; those of the central bars were better marked; in spite of the difference in the crystallization the results were identical in both ingots, which shows that the difference in the results given by test-pieces along the edge and those from the center in the previous tests cannot be attributed to this cause, and was probably due to a slight degree of center porosity produced during solidification.

Second Group

An ingot from basic open-hearth cast No. 930, to which reference has previously been made, was cropped 40 per cent from the top, after which a slice 120 mm. thick was taken and divided into four portions, as shown in Fig. 2. The treatments to which each part were submitted were as follows:

Slab No. 1 was water-quenched from 1,050 deg. and then forged between 950 and 800 deg.

Slab No. 2 was water-quenched from 1,050 deg. and then forged between 1,100 and 950 deg.

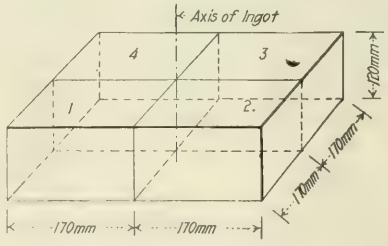


FIG. 2

SUBDIVISION OF INGOT 930

Slab No. 3 was given the same treatment as No. 2 above.

Slab No. 4 was unquenched but forged between 1,100 and 950 deg.

The slabs, which were originally 170 x 170 x 120 mm., were reduced by

forging to flats, 200 mm. long and 35 mm. in section, their length being parallel with the 120 mm. side—that is to say, with the axis of the ingot. Tensile test-bars were then cut in the directions of the thickness and width of the flats and the results obtained gave rise to the following observations:

First, quenching prior to forging effected no improvement.

Second, the fractures were "woody" whether forging was carried out between 1,100 and 950 deg. or between 950 and 800 deg.; except that the streaks were less marked in regard to the bars from slabs forged between 1,100 and 950 deg.

Third, the differences were fairly marked according to the position from which the test-pieces were cut. Those corresponding with the edges of the ingot were better than those corresponding with parts in the neighborhood of the centers.

Thus, with this ingot, of fairly large dimensions, the same peculiarities occur as in the small ingots of crucible steel cast in the laboratory.

Third Group

The test-bars were cut transversely from a 75-mm. gun tube forged from an ingot of cast 930, which furnished the slabs described above. They were divided into two groups. Those of the first set were quenched in water from temperatures of 780, 850, 1,000, 1,100 and 1,170 deg. respectively, as soon as the pyrometer showed that the required temperature had been reached. Those of the second group were treated the same way except that the temperature was maintained for one hour before the bars were quenched.

All the fractures showed lines; a slight improvement was, however, detected in the bars kept at between 1,100 and 1,170 deg. for an hour before quenching.

To conclude, it would appear that forging at a high temperature, and that quenching after keeping at a high temperature, will both improve the results, although this improvement is insufficient.

Tests on Various Special Steels

During the years 1894 to 1898 a large number of special steels had to be examined transversely in the laboratory, and the conclusion was arrived at that good results could be obtained—the fractures being free from streaks—when the carbon percentage did not exceed 0.25, even with fairly high percentages of the special elements, reaching, for example, in the case of nickel, as much as 7 per cent.

As a result of these conclusions a certain number of casts were made from an open-hearth furnace, some on a basic lining and others on an acid lining. Those made by the basic process showed few or no lines, but side by side with test-bars giving good fractures were others showing small whitish stains, oval and in all probability identical with the defect which has recently been described in various English and American reviews under the name of flakes, which prevented such steels being accepted as suitable metal for guns.

The casts from the acid open-hearth made with all the precautions observed in gun manufacture, such as much slower working of the charge and charging in several relays, gave on the contrary excellent results. Table II gives those obtained on a 75-mm. gun tube forged from an ingot of the first cast made under these conditions. Test-pieces were 13.6 mm. in diameter and 50 mm. long, cut transversely in the middle thickness.

The composition of this cast was: Carbon, 0.24 per cent; silicon, 0.216 per cent; sulphur, 0.022 per cent; phosphorus, 0.031 per cent; manganese, 0.43 per cent; and nickel, 5.55 per cent. The average working was 3:4.

This composition showed that the upper limit of 0.25 per cent fixed for the carbon may be raised to 0.30

TABLE II TESTS OF NICKEL STEEL FROM ACID OPEN-HEARTH

Treatment	Location of Specimen	Elastic Limit*	Tensile Strength*	Elongation, per Cent	Reduction of Area†
Annealed after forging at 900 deg.	Front	42.7	61.0	24.5	0.460
	Back	43.0	61.3	24.0	0.453
Quenched in water at 900 deg. C. and again quenched at 620 deg.	Front	61.0	82.5	19.0	0.389
	Back	57.7	79.5	23.5	0.468

NOTE—All fractures were what is known in England as "half-cup."

*In kg. per sq.mm.

†$(S - S^1) \div S$

and, even with 5 to 6 per cent of nickel, yield excellent fractures.

A fact that supports the foregoing contention on the subject of the upper limit of the carbon is the following:

During the war tests were made of six breech sleeves from abroad for 155-mm. guns. Five of these pieces had a composition closely agreeing with the above: Carbon, 0.25 per cent; silicon, 0.25 per cent; manganese, 0.50 per cent; nickel, 3.60 per cent; and chromium, 0.80 per cent. They yielded excellent fractures.

The composition of the sixth was: Carbon, 0.34 per cent; silicon, 0.32 per cent; manganese, 0.70 per cent; nickel, 2.76 per cent; and chromium, 0.115 per cent. These bars gave the same elastic limits and tensile strengths as the previous ones, but the elongations and reductions of area were much smaller and the fractures were woody.

Transverse Tests on Nickel Steels

The upper carbon limit of about 0.30 need not be kept to as long as the percentage of nickel does not exceed 2.5 per cent. Thus some hundreds of gun-steel casts have been made at Creusot by the acid process with carbon percentages of 0.35 to 0.50 and with 1.8 to 2.4 per cent of nickel, with excellent results when tested in a transverse direction. With more than 2.5 per cent of nickel, however, it is necessary to diminish the carbon in order to avoid woody fractures. This fact appears to the author a strong argument in favor of the hypothesis put forward, namely, that defective transverse results and correspondingly woody fractures may arise, not only owing to the presence of inclusions or blowholes or to overworking, but also owing to the chemical composition of the metal.

It can indeed hardly be doubted that if it be possible to make two casts by the acid open-hearth process, and with every imaginable precaution, one with, for example, 0.25 per cent of carbon and 4 per cent of nickel, and the other with 0.40 per cent of carbon and 4 per cent of nickel, it is more difficult to avoid oxidation and the presence of inclusions in the former than in the latter, yet, however, the former will give good transverse fractures and the second will give streaky fractures even when the treatment has been adjusted so as to give in both instances the same tensile strength on testing.

The latter condition is necessary to afford comparisons, as it may often be found that a steel which in the annealed state does not show a streaky fracture will show streaks once quenching has increased its tenacity. It appears probable to the author that the improvement due to a low percentage of carbon is the result of less segregation around the dendritic crystals formed during solidification, owing to the greater speed with which this takes place.

Improvement of High Carbon-Nickel Steels

The program of these experiments was drawn up in order to investigate the influence of percentages of carbon above 0.30, the end temperature of forging, the coefficient of working, and the position of the test samples with regard to the ingot. With these objects, four ingots of 130 x 130 mm. section, and weighing about 75 kg. each, were cast from the crucible furnaces of the steelworks, the lower ends of the ingots being smaller than the tops. Their composition is shown in Table III.

TABLE III. COMPOSITION OF NICKEL INGOTS

No. of Cast	Carbon per Cent	Silicon per Cent	Sulphur per Cent	Phosphorus per Cent	Manganese per Cent	Nickel per Cent
919	0.320	0.272	0.026	0.039	0.480	3.22
924	0.330	0 280	0.026	0.037	0.440	3.30
1004	0 451	0 257	0.030	0.037	0.500	3.25
1005	0.434	0.224	0.028	0.041	0 490	3.22

Forging

These ingots were forged under a 2,000-kg. hammer. The ingots from casts 919 and 1,005 underwent three reheatings at between 1,075 and 625 deg. C. The other

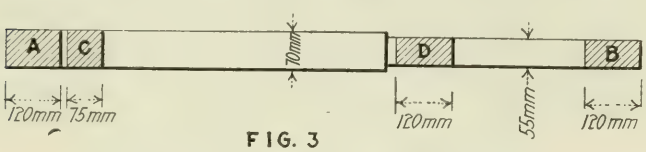

FIG. 3

TEST-PIECES FROM NICKEL FORGINGS

two were forged in five heats at temperatures between 1,050 and 600 deg. Table IV shows the dimensions of the pieces after forging as well as the percentage crops top and bottom.

TABLE IV. FORGINGS FROM NICKEL INGOTS

Cast	Bottom Crop, per Cent	Coefficient of Working 1:4, mm.	Coefficient of Working 1:7, mm.	Top Crop, per Cent
919	6.6	880	540	33.6
924	5.9	870	530	32
1004	5.6	860	460	32.5
1005	5.4	870	400	29.8

After forging the four rounds were annealed at 950 deg. and air-cooled. From each end of each round, a piece 120 mm. long was cut, marked A and B (see Fig. 3). The pieces taken from the bottom end were drilled along their axes with a hole 20 mm. in diameter, and those from the top end with a hole 10 mm. in diameter, in order to secure approximately the same thickness of metal and to be able to obtain smaller bars.

In casts 919 and 924 only, there were then cut, about midway along the length but on the portion reduced to 55 mm., a sample D, 120 mm. in length, and from the bottom end a sample C, 75 mm. long, which was reforged to 55 mm. The forging down was carried out at the same temperature as the first forging, that is to say, between 950 and 625 deg. for the round from cast 919 and between 1,000 and 900 deg. for the round from cast 924. The lengths obtained were like the previous ones bored with 10-mm. holes.

By acting thus it was possible to determine:

First, the influence of the carbon by comparing the results of the tests of the lengths:

A. Casts 919 1005	A. Casts 924-1004
B. Casts 919-1005	B. Casts 924-1004

These lengths have, in each series, undergone the same amount of working and the same method of forging. They likewise occupy the same relative positions in the ingot. The percentage of carbon is the sole difference between them.

Second, the influence of the end temperature of forging, by comparing the results of the tests of the lengths:

A. Casts 919-924	D. Casts 919- 924
B. Casts 919-924	A. Casts 1005-1004
C. Casts 919-924	B. Casts 1005-1004

These lengths had, so far as each series was concerned, undergone the same amount of work; they occupy the same relative positions in the ingot and have practically the same percentages of carbon. They differ solely in respect to the end temperatures of forging.

Third, the influence of the amount of working, by comparing the results of the tests of the lengths:

A and C in cast 919	A and C in cast 924

These lengths have the same carbon percentages and have undergone, in pairs, the same method of forging and occupy the same relative positions in the ingots. The amount of work they have undergone is their sole difference.

Fourth, the influence of the relative positions of the samples in the ingots, by comparing the results of the tests of lengths:

C, D and B in cast 919	C, D and B in cast 924

These lengths have the same carbon percentages; have undergone—as regards each cast—the same method of forging, and have undergone the same amount of work. Their positions, in respect to the ingots, are their sole differences.

All the lengths forged to 55 mm. were machined down to 50 mm., and the 70 mm. lengths were machined

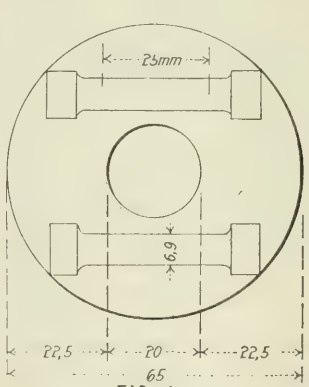

FIG. 4

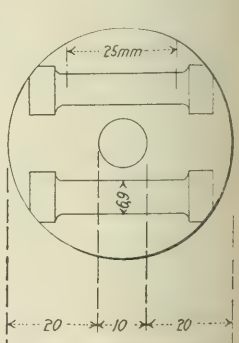

FIG. 5

METHOD OF CUTTING TRANSVERSE TEST-BARS

down to 65 mm., after which they were again annealed at 850 deg. and air-cooled. From each of them a rod 12 mm. thick was then cut for testing before quenching. Each rod furnished two tensile test bars 6.9 mm. in diameter and 25 mm. in length between punch-marks (homologous with those 13.9 mm. in diameter and 50

TABLE V. TESTS ON HIGH NICKEL-CARBON STEELS

*Tests made on a second bar. Strengths in kg. per sq.mm.

mm. long between punch-marks). These bars were cut as shown in Figs. 4 and 5.

The rods were subsequently quenched in oil from 875 deg., and in water from 640 deg. A fresh rod 12 mm. thick was taken from each sample and sliced as before.

The accompanying Table V sums up the results of these tests. In the column headed "fractures" the figures 0, 1, 2, 3, 4 and 5 have been used to signify the relative proportion of streaks. Those marked 0 show none; those marked 5 reveal the most.

By instituting the comparisons as already described, so that in each instance there is but one variable, it is found:

First, as regards the influence of the carbon: In eight examples five are favorable to the less highly carburized casts; one gives identical results in both cases, and two favor the more highly carburized casts. It may therefore be concluded, as before, that from the point of view of the test results it is advantageous to reduce the carbon percentage.

[EDITOR'S NOTE:—These figures are compared in Table VI. The author's comparison apparently has to do with the condition of the fracture. Averaging the figures, it appears that increasing carbon from 0.325 to 0.442 per cent increases the elastic limit of an annealed bar 4.4 kg. per sq.mm., increases the ultimate 6.9 kg. per sq.mm., decreases the elongation 2.1 per cent, the contraction 6.5 per cent, and increases the number of streaks in the fracture by about one-tenth. In tempered bars, the higher carbon increases the elastic limit 7.8 kg. per sq.mm. and the ultimate 8.2 kg., decreases the elongation 4.7 per cent, and the contraction 6.5 per cent and increases the number of streaks by about one-fifth.]

Second, as regards the influence of the end temperature of forging, it is found that out of twelve instances six favor high finishing temperatures, three are identical both as to high or low finishing temperatures, and three favor low temperatures. From this the conclusion can be drawn that it is preferable to finish the forging at as high a temperature as possible.

[EDITOR'S NOTE:—The figures again are compared in Table VII. It appears that in annealed bars decreasing the temperature of forging from 925 to 700 deg. C. leaves the elastic limit and condition of fracture practically unchanged, but decreases the tensile strength, the elongation and the contraction slightly. In tempered bars the results cover a wider range, but their average is nearly negligible, except that the number of streaks is increased about 10 per cent.]

Average	— 1.1	+ 1.3	0.8	0.004	+0.5

Third, in regard to the amount of working the results are indecisive. There are two instances where the 1: 4 working is advantageous and two instances where it is the reverse. The author believes this to arise from the small number of tests and, more especially, from the small dimensions of the ingots. [See Table VIII, by the Editor.]

Fourth, from an examination of the results from the bottom, the center and the head of the ingots it results that the bottom portion is distinctly better. The difference between the other portions is inappreciable. [See Table IX, by the Editor.]

Fifth, it should likewise be noted that, generally speaking, the fractures are more woody after quenching than in the annealed bars. Thus, the tests, before quenching, on test-pieces from the bottoms of ingots worked 1: 4 show no streaks, although they show them after quenching and annealing.

Conclusions

To sum up: What this investigation brings out is that forging finished at a high temperature improves the results of transverse tests, although it does not do so sufficiently. Hence, if very good results be sought it is preferable to diminish the percentage of carbon to below 0.30 per cent, if the percentage of nickel has to be increased in order to obtain the necessary tensile strength after quenching.

In addition to the part played by non-metallic inclusions, blowholes and amount of working, in giving bad results in transverse tests of forged parts, it is necessary to take into consideration the chemical composition of the steels and particularly of the percentage of carbon. When this is below 0.30 per cent, and better still below 0.25 per cent, good results are obtained if the metal has been properly made, even when adding a sufficiently high percentage of special metals to secure very high tensile strength after quenching and annealing. This rule applies up to steels which have undergone a 1: 8 working, but the author has no experience of higher coefficients of working.

It is not necessary to lower the carbon in nickel steels so long as the percentage of nickel is below 2.5. Very good results are indeed obtained with percentages of carbon reaching 0.5, as has been shown by numerous tests on steel manufactured for ordnance.

It would appear that the transverse tests are improved if the forging of the ingot be wholly carried out at a high temperature, but this improvement is insufficient when the maximum results are required in transverse strength, for example, in the case of steel for guns.

The different tests described in this paper, having been carried out at different times and over a prolonged period, lack the co-ordination they might have possessed had they been carried out as a whole. For this the author offers his apologies.

Growth of Research Associations in England

The formation of combinations or associations of specific trades for the purpose of research work under the British Government's plan, whereby $4,866,500 is made available for industrial research, continues to become more frequent. Research associations have been formed in connection with chocolate, cocoa, sugar, confectionery, jam, boot and shoe and allied trades, cotton, sugar, iron, motor and allied manufactures, photographic materials, portland cement, woolens and worsteds, scientific instruments, india rubber and tires, linen, and glass industries. The scientific and industrial research department has given its sanction to the formation of similar associations for refractory materials, non-ferrous metals, and Scottish shale oil. Other trades or industries whose applications have been made for the department's approval include launderers, electrical and allied industries, and makers of aircraft. Silk manufacturers, leather trades, master bakers and confectioners, and manufacturers of adhesives have under consideration details of proposed associations.

Before any association can come under the government scheme, the approval of the scientific and industrial research department must be obtained, and subsequently a license must be secured from the Board of Trade. The associations must be national in character and include the bulk of the manufacturers in any specified industry. A legal status is obtained through registration as a company under section 20 of the companies consolidation act, 1918. The associations are limited by guarantee of a nominal sum and may not divide profits; but the contributions of firms, being regarded as business costs, are exempted from income tax. The general scheme is to provide £1 from the department for every £1 subscribed by members up to five years after organization; but should an association's expenditure exceed £6,000 a special arrangement may be agreed to.

At present, the largest associations are those of the cotton and woolen industries. In the cotton association, growers, spinners, manufacturers of loom and knitted fabrics, dyers, bleachers, and finishers are combined; all sections of the woolen trades are represented in the association of woolen industries. With a view to improving supplies of wool, a conference has recently taken place between the woolen association and the Scotch, Welsh, and English sheep breeders.

Origin of the British National Physical Laboratory

At the recent Bournemouth meeting of the British Association for the Advancement of Science, the treasurer, Prof. John Perry, stated that the National Physical Laboratory, the scene of researches of which the importance to the nation during the war cannot be overestimated, had its origin in the Kew Observatory, which was maintained by the Association from 1842 to 1872.

A New Cyanide*

Description of the Process for Converting Calcium Cyanamide to a New Cyanide in a Modern Sodium Chloride Solution—Early European Developments—Recent American Achievements—Products and Production—Applications

By W. S. LANDIS

ABOUT thirty years ago the new use of cyanide in the gold industry brought to the attention of the chemical world the necessity of producing this material on a larger scale than previously, and at the same time of finding cheaper methods of preparation if the compound was to have an extended use. American, French, English and German chemists attacked the problem most energetically, and from their work arose the present-day processes, with which, as far as they have become commercially practicable, you are probably familiar.

Two German chemists, working on the barium carbonate process about twenty years ago, attempted to supplant the expensive barium salt with a cheaper calcium salt, and obtained a new product, cyanamide, which afterward formed the basis of development of the well-known cyanamide process. To a certain extent they were disappointed at the outcome of their work, as the new product, calcium cyanamide, had little in common with the object of their search, and after its discovery they sought for many years to convert cyanamide into cyanide. Their first patents on this transformation of cyanamide into cyanide were taken out eighteen years ago, these patents covering a process of fusing crude cyanamide with common salt in the proportions preferably of one part of cyanamide to two parts of sodium chloride. The mixture of cyanamide and sodium chloride was to be heated to fusion and until foaming of the mass ceased, which operation was reported to require from ½ to 1 hr. The resulting product was reported to contain cyanide of calcium, but no analyses were given.

In attempting to carry out this process on a commercial scale, apparently they met with a great deal of difficulty. I visited their plant in 1914 and found a great many types of equipment had been installed at one time or another, none of which had worked successfully, and the cyanide plant had been closed down and abandoned for several years.

Types of Equipment Tried and Abandoned

The earliest type of apparatus consisted of a row of iron crucibles set in a gas-fired furnace with the top flush with the roof of the furnace. These crucibles were about 48 in. deep and 20 in. in diameter and had been made at various times of cast iron, cast steel and welded soft steels. In operation salt was melted in the pot and cyanamide was then stirred in and the whole mass kept fused for a suitable length of time. The transformation efficiencies were extremely low, but no actual record of the same was made public.

The next development consisted in setting two iron crucibles side by side in the furnace. In one crucible they charged salt and melted it, and in the second they charged cyanamide and heated it to redness. Molten salt was ladled from the first crucible to the second, and when a proper quantity had been added the whole mass was kept melted until by chemical analysis the maximum yield of cyanide had been attained. The contents of the pot were then ladled out and cast into slabs.

The enormous amount of hand labor involved in this operation rendered it commercially impracticable, and a new equipment replaced the old. A revolving furnace was constructed with an enlarged melting hearth midway between the tires. Salt was melted in this hearth and tapped into an iron ladle and conveyed to a crucible containing red hot cyanamide. This operation was also unsuccessful in that there was considerable wear and tear on the salt-melting furnace, and further, great care had to be exercised in pouring the molten salt onto the heated cyanamide, as the initial reaction was very violent and the pot frequently boiled over.

The maintenance of the externally heated crucible at the required high temperature became quite burdensome, and a new type of furnace was developed in which an iron pot, provided with a spout, was set into a fuel-fired furnace. This pot was built of welded flange steel. It was 3 ft. deep and 2½ ft. in diameter. There was also provided an electrode 5 in. square hung on a chain block in line with the axis of the pot so that it could be lowered into the fused mass. In this way a single-phase furnace using about 40 volts and 1,200 amp. was made in a setting also provided for initial fuel firing. In operating, cyanamide was charged into the bottom of the pot and heated to redness by the fire underneath. Salt was melted in the rotating furnace previously described and was slowly poured into the electric furnace at such rate that no very violent reaction ensued. The carbon electrode was then lowered, the current turned on, and the whole mass kept heated electrically until the reaction was complete. The cyanide was tapped through the spout and cast into slabs.

This furnace and process were not successful—the efficiency of nitrogen transformation was very low and the final product contained a comparatively small percentage of cyanide. I was informed, however, that the same type of furnace was being used successfully in another part of Germany, where the salt was melted electrically, and there was being turned out in this second plant a grade of product containing 40 per cent equivalent potassium cyanide at an efficiency of nitrogen transformation of over 90 per cent. I accordingly visited this other plant and was much surprised to find there an entirely different type of apparatus in use.

Uneven Heating Cause of Low Efficiency

At this second place I found they had tried the combined fuel-fired and electric furnace just described, and had come to the conclusion that the uneven distribution of electric energy throughout the bath caused very uneven heating of its contents, which was believed to be the cause of the poor efficiency obtained from the process. The iron pot would last only two or three runs, due to cracking, and they had abandoned this type of apparatus for a resistance type of electric furnace built

*Read at the meeting of the New York Section of the American Electrochemical Society, Jan. 23, 1920.

of brick. This improved furnace was of the tilting type with a rectangular hearth and arch roof and lined with magnesite brick. The side walls were formed of carbon blocks and electrically connected with a source of current. In practice these blocks were short-circuited with a rod of carbon, and salt was thrown into the furnace and melted around the rod, thus establishing a path of current between the side electrodes. The furnace was then filled with salt. Cyanamide was added to the melted bath and the heating continued until, as shown by chemical analysis, the maximum content of cyanide had been formed, when the molten bath was poured out and cast into slabs. I witnessed several operations of this furnace and found that the furnace produced about 400 kg. of molten product in from 3 to 4 hr. The apparatus used about 21 volts and 2,800 amp. The equivalent potassium cyanide in the final product ran from 8½ to 17½ per cent in the various runs and the nitrogen transformation efficiency from 40 to 75 per cent. During the last run I witnessed, the furnace became blocked with a white spongy material and all operations were abandoned.

It is thus apparent that in the fifteen years elapsing between the initial experiment and my visit the Germans had been able to do little or nothing with the process of transforming cyanamide into cyanide. They had tried out many types of furnaces, none of which was successful in any marked degree, and had produced only a small amount of product of comparatively low grade and at great inefficiency. They were firmly convinced that it would be necessary to use more than two parts of salt to one part of cyanamide in order to make reaction take place at all and that for smooth working at least three parts of salt to one of cyanamide was absolutely necessary, also premixing of the charge was wrong chemically and must not be used. On the basis of these mixtures the final product should test between 15 and 20 per cent of equivalent potassium cyanide. There were many theories and ideas advanced on the subject, but I could find no comprehensive chemical study of the process and little information of scientific value. In fact, the outlook for this transformation was most discouraging.

Resistance Furnaces Tried in America

In the late fall of 1916 there was a sharp advance in the price of cyanide in this country and a great shortage in the available supply. The gold and silver mills of the continent faced a serious situation, and finally one of the large users of the material came to the American Cyanamid Co. with a request that it endeavor to co-operate in producing the necessary requirements of this material. With the discouraging report on the German process in hand and no time available for experimental work, the outlook was not particularly bright, but the problem was attacked and a plant was designed and equipped, using resistance furnaces of a modified design, and the older German procedure was altered somewhat with the hopes of obtaining results at least as good as the Germans had anticipated.

This plant was put into operation at Niagara Falls late in December, 1916. It was provided with five resistance furnaces of a tilting type and two salt-melting furnaces of fixed type. While completing the salt-melting furnaces, the resistance furnaces were put into operation as combined salt-melting and reaction units. They were very much larger than the German furnaces and the design and construction were quite new. They functioned extremely well as such furnaces go, considering the complicated operation. The time of an operation, including salt melting and reaction, was reduced to about 2½ hr., and the salt-melting furnaces were never used for their intended purpose.

Salt, charged cold, was first melted by adding it directly to the hot furnace, the heated walls conducting sufficient current to start the melting. Into this bath of molten salt cyanamide was fed by hand, the bath stirred up with an iron rod, and as soon as all the cyanamide was in, the furnace was tapped by pouring into chill cars. After cooling, the cake was broken up and loaded into caustic soda drums, which formed the shipping container of the final product. Later it was tapped directly into the shipping drums.

Improvements in the Process

The process was somewhat troublesome to carry out. The life of the low-grade magnesite brick lining, the only kind then obtainable, was at most six weeks. It then became so conducting, due to the iron content of the bricks being reduced by the cyanide and through its absorption of the cyanide itself, that relining was necessary. Further, the addition of the cyanamide had to be slow and cautious, as considerable foaming took place during the reaction and the contents of the furnace would frequently boil over. The first great improvement was the discovery that the addition of a very small amount of calcium carbide to the furnace would entirely stop the foaming. This permitted the cyanamide addition to be made very quickly, and the power input was, therefore, increased to obtain the additional melting speed. I had learned in Germany that the furnace men over there were of the very fixed opinion that at no time should the temperature of the bath rise above 960 deg. C. or decomposition of cyanide would result. Due to an accident to the electrical system at Niagara one of the furnaces received an undue amount of electrical power in one of the runs and the temperature shot up several hundred degrees above the limit set by the Germans, yet most excellent results were obtained. All furnaces were, therefore, operated at the highest possible temperature, and as a result within three months of the starting of the plant the Cyanamid Co. not only maintained a daily production rate of nearly four tons of sodium cyanide but had carried on experimental work which had enabled it to dispense entirely with the salt-melting furnace as well as some of the reaction furnaces, to cut down the time of reaction to half, to avoid foaming, and further to increase the test of the finished material up to approximately 24 per cent equivalent sodium cyanide.

New Type of Furnace Tried

The unsatisfactory performance of the tilting furnace led the company to experiment with a new type using a suspended electrode and the combination arc-resistance method of heating. The success following this development enabled it to abandon the numerous small-resistance furnaces and concentrate its efforts in a single unit and at the same time obtain a very greatly improved product. After a short period of development there was constructed at Niagara a single-phase furnace with conducting hearth and a single suspended electrode. This furnace started with an initial capacity of ten to twelve tons of product per day running about 28 per cent sodium cyanide equivalent, but it is now operating at nearly thirty tons of product per day aver-

aging 36½ per cent equivalent sodium cyanide. Additional furnaces are in process of construction.

Rapid Development of the Industry

The development of the industry has been quite rapid. In 1917 there was produced approximately 2,187,000 lb. equivalent of 100 per cent sodium cyanide. In 1918 this grew to 2,350,000. In 1919 a very considerable revision of the process and equipment was made, and as a consequence the plant operated only seven months, during which period it produced at the rate of over 4,000,000 lb. of NaCN per year. The quality of the product started at about 14 per cent equivalent sodium cyanide in January, 1917, and in August, 1919, ran uniformly between 36 and 37 per cent equivalent sodium cyanide. Material running as high as 50 per cent equivalent sodium cyanide has been produced and there have been shipped several carloads running around 45 per cent, of which I shall speak more later.

The process and apparatus used for manufacturing this product have been extensively described in the many United States and foreign patents covering the process. Essentially, cyanamide, salt and calcium carbide are mixed together and continuously fed to a single-phase furnace designed so that it has a very small cubical capacity as compared with the power input. Melting is extremely rapid and the fused product is removed from the furnace almost continuously to a cooling device, which instantly chills the product. This is necessary to prevent reversion of the initial reaction, whereby calcium cyanamide plus its contained carbon is converted into cyanide. The proportions of cyanamide and salt vary with the product to be made.

In 1917 operations were started with two parts of salt to one part of lime nitrogen and gradually decreased in salt content until, in making the present standard 36 to 37 per cent product, more cyanamide than salt is being used. The large furnace has been successfully operated with proportions as low as two parts of cyanamide to somewhat less than one part of salt, and the experimental furnace with no salt whatever.

The Product and Its Application in the Cyanide Process

The resulting product is marketed in the form of small thin scales of a grayish black to shiny black appearance, and the standard grade, known as Aëro Brand Cyanide "Grade X," contains between 36 and 37 per cent equivalent sodium cyanide. This method of expressing its composition is used because it is sold on the basis "per lb. of sodium cyanide equivalent." A constitutional analysis of the material has so far proved impossible of execution, but evidence points to the fact that it consists of a mixture of calcium cyanide, sodium chloride and free lime, with fractions of a per cent each of calcium carbide, calcium cyanamide, and other minor impurities obtained from the ash of the coke used in cyanamide manufacture. The product known as Aëro Brand Cyanide "Grade XX" contains about 45 per cent equivalent sodium cyanide—the cyanogen being actually present as calcium cyanide—a slightly higher percentage of free lime and a materially lower percentage of salt than the X grade.

As to the use of this material, it has found an enthusiastic reception in the mining industry. Being made from cyanamide, one of the cheapest forms of combined nitrogen, and common salt, its cost of manufacture and its selling price are materially less than the purer forms of cyanide hitherto on the market. The use of caustic soda drums for packing has cut down the expensive item of metal containers forced upon the early industry.

Use in the Precious Metal Industry

The first of this cyanide made in 1917 went into the precious metal industry after a short series of laboratory tests in which it was demonstrated that it would dissolve gold and silver with equal efficiency to the 98 per cent grade then in the market, and that the accumulation of soluble salts due to the cyclical use of solutions in the mill would not prove troublesome. In mill operations the drums were opened and the cyanide placed in a revolving tumbler which dissolved it in water, thus giving an opportunity for any acetylene produced to be evolved outside of the mill solutions. Containing as it does a small amount of insoluble material, part of which is carbon, difficulty with precipitation due to the presence of this carbonaceous material was feared, and the solutions were therefore filtered before passing into the mill circuit. Experimental work quickly determined that the carbonaceous residue had no precipitating effect upon cyanide solutions of the precious metals, and this early practice of presolution was quickly abandoned and from then to the present time the new cyanide is dumped directly into the mill circuit.

The presence of a small amount of sulphur in the cyanamide is carried through into the cyanide as a sulphide. Difficulty was feared with the presence of this sulphide, but several years' experience has shown that the aëration as employed in the cyanide mills quickly oxidizes these sulphur compounds and renders them harmless. As a result no trouble has been experienced from its sulphur content.

In the gold industry, where the cyanide consumption per ton of ore is comparatively small, no difficulty has ever been experienced with the accumulation of soluble salts. In the silver industry, where cyanide consumptions of not over 5 lb. equivalent potassium cyanide per ton of ore are experienced, they have similarly had no trouble from accumulation of the soluble salts, but where consumptions are considerably above that figure certain difficulties have made themselves known in several of the silver mills. The calcium chloride obtained from double decomposition of calcium cyanide and sodium chloride acts as a precipitating agent and greatly assists in the settling of the mill solutions. Its accumulation in such a solution, however, to an undue extent, particularly in the case where cyanide consumptions run from 10 to 100 lb. per ton of ore or concentrates, leads to a decrease in the available alkalinity of solutions, and steps have had to be taken to eliminate it. These steps consist in the addition of any simple precipitating agent for lime, the precipitated lime being removed in the filter with the mill tailings.

Advantages of the Product

In every case, either in the laboratory or in the mill, the cyanogen content of Aëro Brand cyanide has proved itself equally as efficient in the extraction of precious metals as that of the 98 per cent sodium cyanide pound for pound of contained cyanogen, added to which are the advantages of a considerably lower cost, slight alkalinity, and the marked influence on the rate of settling of slime in the solution. The new product has found a most favorable reception in the industry and is very widely and extensively used today. In the gold

mills it offers no problem in handling and causes no difference in the practice beyond the fact that the making up of a stock solution is not considered as good practice as the dumping of the cyanide directly into the barren solution along with the ore. In the silver mills, using a considerable quantity of cyanide per ton of ore, simple precipitating methods for eliminating accumulated lime are in use, otherwise their practice is in no way affected.

In its present state of development the new cyanide is not adapted to use in the case-hardening industry or in electroplating. For the case-hardening industry it is very questionable if it has anything to offer in the future, but in the electroplating industry steps are being taken to perfect a method to simply convert it into forms such as the electroplater can conveniently use, and it will undoubtedly make some headway in that industry.

Preparation of Cyanides, Pigments and Prussic Acid

For the preparation of cyanides it is a simple matter to dissolve the new product in water, adding sufficient soda ash to eliminate the lime, and filter. It is then ready for precipitation of the various insoluble cyanides.

For the preparation of ferrocyanide it is very satisfactory. A solution of ferrous sulphate is made up of suitable strength, and into this is dumped an equivalent amount of Aëro Brand cyanide and the mass agitated for a short time. Quantitative transformation of the cyanogen to ferrocyanide readily takes place. The insoluble material left in the treatment vat is filtered off, the filtering operation not being very complicated, but the amount of cake to be handled is considerable. The resulting ferrocyanide is then concentrated, and at a certain density about 95 per cent of it will separate out as a meal and the other 5 per cent will remain behind in solution with the chlorides of calcium and of sodium. The meal is separated in a salt filter attached to the evaporator and the solution is thrown away. Recrystallization of the meal with return of mother liquor to the original treatment tank yields a sodium ferrocyanide of remarkable purity. The transformation can be accomplished with not over 5 per cent loss of cyanide.

Recently the manufacture of anhydrous prussic acid from the crude cyanide has been successfully undertaken. Into an acid-proof generator, cyanide and water is charged, the apparatus closed and sulphuric acid run in. A considerable evolution of prussic acid gas takes place, and the solution in the generator is finally cleared of all prussic acid by the admission of live steam. A brine-cooled condenser liquefies the gas evolved from the still and condenses an impure acid containing about 80 per cent prussic acid. This is charged into an iron still and re-evaporated, the resulting condensate being about 98 per cent pure, in which state it is used in fumigating in the citrus-growing districts. The resulting liquefied product is water white and practically chemically pure, at most containing only minute traces of foreign products. The construction and operation of the liquid gas plant, as it is called locally, has been a most successful operation in every way, the only regret being that the installation was not about three times as large as originally planned, because of the great demand for the high quality material it has turned out.

There is no reason to doubt that this new cyanide will find a place in many other chemical industries, as up to the present time practically no limitations in its use have been found and no chemical properties which prevent its utilization in the many cyanide derivatives.

Quite recent developments have shown the feasibility of manufacturing the higher grade product containing about 45 per cent equivalent sodium cyanide. These developments are too new to present at this time, and a discussion of the process or of the use of the resulting product, which has several new characteristics, will be reserved for the future.

Conclusions

The development of the process of transforming cyanamide into cyanide marks another triumph of the American electrochemist.. We accomplished more in a few months than the foreign chemists accomplished in fifteen years. Three months after starting the designs of a plant our American chemists were producing to the extent of four tons of equivalent sodium cyanide per day of a much higher grade than the Germans had ever hoped for. Within a year we had reduced our operation to a single small electric furnace of a continuous type and produced a product of higher cyanide content than the Germans ever thought possible and at a nitrogen efficiency of over 90 per cent.

The resulting product, of uniform quality and excellent physical characteristics, has found a very increasing market in the various industries using such a product and is today pushing the pure high-grade product steadily out of its long entrenched fields. For the present year the outlook is for a consumption of Aëro Brand cyanide equivalent to nearly 5,000 tons of 100 per cent sodium cyanide. With further development along the lines of transforming this material into its many other derivatives, particularly in view of the very low cost of the raw materials entering into its manufacture, and the simple apparatus and process used, we confidently look forward to cyanide made from cyanamide dominating the world's cyanide market.

Laboratory for New York Department of Health

The Board of Estimate and Apportionment of the City of New York has voted a $1,000,000 appropriation to construct a new building for the Department of Health. Three or four floors will be given to laboratories. We wonder whether the gentlemen attached to the Board of Health laboratories who have lately joined a labor union will celebrate the completion of the building by a strike. Or if a non-union plumber is called in will they be obliged to quit work? Or suppose, in a threatened epidemic, Dr. Simon Flexner or Dr. Jacques Loeb were invited to come and help. So far as we are aware, despite all their scholarship and achievements, neither of these gentlemen has a union card; and if the laboratories are completely unionized they will become closed shops, whereby both distinguished savants would become "scabs."

Box-Making Course at Forest Products Laboratory

The Forest Products Laboratory is offering a course in box- and crate-making of particular value to superintendents, shipping-room foremen and others of similar qualifications. The course will require one week's time for a fee of $10. Application for enrollment should be made to the director, Forest Products Laboratory, Madison, Wis. The first week opened Jan. 26, and repetition will be made as often as found desirable.

A Study of the Lime-Soda Ash Water-Softening Process

Observations on the Changes in Alkalinity and Hardness With the Addition of Lime and Soda Ash Separately and Consecutively to Hard Water—Effects of Insufficient, Correct and Excessive Amounts of Reagents

By MAX R. HERRLE and FRANCIS M. GLEESON

IN THIS article it is our desire to call particular attention to that branch of factory control relating to the filtering, softening and purifying of water. It is an accepted fact among power plant engineers and users in general that pure clear water is essential for industrial as well as domestic use, and especially that soft clear water for boilers is a great factor in expense saving by reducing fuel bills, repairs and labor incidental to keeping boilers and heaters clean and in first class working condition.

All water on this earth has descended from the clouds at one time or another. This water in its descent has absorbed carbonic acid, air and many other impurities. The carbonic acid absorbed enables the water to dissolve many salts, chief among them being those of lime and magnesium. The common impurities are:

1. Carbonates of lime, magnesium, sodium and potassium.
2. Sulphates of lime, magnesium, sodium and potassium.
3. Nitrates of lime, magnesium, sodium and potassium.
4. Chlorides of lime, magnesium, sodium and potassium.
5. Silica and the oxides of iron and aluminum.
6. Suspended matter, as sand and mud.
7. Organic matter.
8. Carbonic acid.

These impurities are common to all waters to a greater or less extent, and it is their removal that has been the subject of many discussions and writings. There are several methods that are adaptable for the removal of these soluble impurities, and a discussion of their adaptability and practicability will now follow.

Three Classes of Water Purification

In a general sense the subject of water purification may be divided into three classes: Distillation, filtration, and chemical purification by precipitation.

Distillation, although ideal, is too expensive to be considered for supplying large quantities of water.

Filtration is of value only when a soft dirty water is to be had, as the dirt will be removed in the process, but should the water be hard due to the presence of soluble impurities, as is the case with most waters, filtration will be of value only after the soluble salts have been converted into the insoluble state.

Therefore, the only method remaining to purify a water for boiler use is chemical purification by precipitation. This method is the one that is used almost universally and the one that will give the best results under the most adverse conditions.

Having discussed the natural substances whose presence in the water supply is detrimental to steam boilers and in other industrial processes, the first thought which naturally occurs in studying the question is the use of some reagent or process which will effectively precipitate the scale-forming material so that the same may be readily removed before the water is used. The complete softening of a water requires the removal both of its temporary and of its permanent hardness. The temporary hardness of a water is caused by the carbonates of lime and magnesium being held in solution by an excess of carbonic acid. These carbonates, which are practically insoluble in pure water, can be precipitated by removing the carbonic acid. This removal is accomplished by means of lime.

This lime is added as a solution and the following equations illustrate the effect of this reagent upon the raw water:

$$CaCO_3 . CO_2 + CaO = 2CaCO_3$$
$$MgCO_3 . CO_2 + CaO = MgCO_3 + CaCO_3$$
$$MgCO_3 + Ca(OH)_2 = Mg(OH)_2 + CaCO_3$$

The lime unites with the acid carbonate of calcium to form the insoluble calcium carbonate, which then precipitates out. It also combines with the acid carbonate of magnesium to produce the insoluble carbonate of magnesium, which is further converted into the more insoluble magnesium hydrate and in turn precipitates out. The lime further effects a practically complete precipitation of the remaining magnesium compounds.

Thus we see that by the addition of lime as a reagent we secure a precipitation of the calcium and a practically complete removal of all of the magnesium compounds because of the fact that the lime removes the carbonic acid which holds the hardness-forming salts in solution.

Permanent hardness of raw water is caused by the sulphates, chlorides and nitrates of calcium and magnesium. Since magnesium compounds have been removed, the remaining permanent hardness of the water is eliminated by means of sodium carbonate, which precipitates the insoluble calcium compounds in accordance with the following equations:

$$CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4$$
$$CaCl_2 + Na_2CO_3 = CaCO_3 + 2NaCl$$

The sodium carbonate unites with the calcium sulphate to give the insoluble calcium carbonate, which precipitates out. The sodium carbonate further unites with the calcium chloride to give the insoluble calcium carbonate.

Thus we see that after the addition of the sodium carbonate all the hardness and scale-forming salts have been removed and only neutral and non-corrosive substances are left in solution.

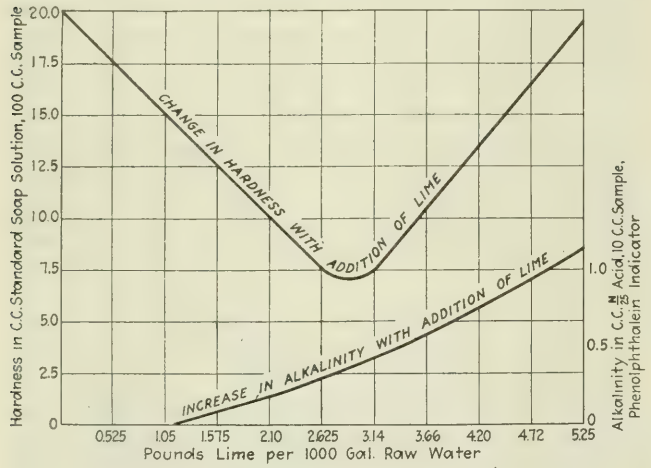
It is now evident that by means of the two reagents, lime and soda ash, an ideal water can be secured with but one problem to face us, that in order to secure this water having a relatively low hardness and alkalin-

ity great care must be taken in adding the reagents. We have carried out a series of tests which we hope will aid in effecting a correct proportioning of the reagents. They are as follows:

Test I. This test deals with the addition of lime to raw water and shows the effect of an insufficient amount of lime, the effect of the correct amount and the effect of an excess.

Test II. This test deals with the addition of soda ash to a raw water and illustrates the effect of an insufficient addition, a correct addition and the effect of an excess.

Test III. This test deals with the addition of both reagents to raw water and shows the correct adjustment of reagents which is absolutely necessary for the production of a good boiler feed water.



Hardness in C.C. Standard Soap Solution, 100 C.C. Sample
Alkalinity in C.C. N/25 Acid, 10 C.C. Sample, Phenolphthalein Indicator
CHANGE IN HARDNESS WITH ADDITION OF LIME
INCREASE IN ALKALINITY WITH ADDITION OF LIME
Pounds Lime per 1000 Gal. Raw Water

CHANGE OF HARDNESS AND ALKALINITY WITH ADDITION OF LIME

Following the tests there is a paragraph dealing with the value of water analysis which also contains the analysis of our raw and treated waters.

Test I. Effect of Lime (CaO) Upon Raw Water

A 30-gal. sample of raw water was taken for this experiment. The water had a hardness of 20.0 deg. with standard soap solution and no alkalinity with N/25 acid, using phenolphthalein as an indicator. The water was treated with successive charges of hydrated lime, which was added as a solution by mixing each charge with some of the water of the original sample. After each addition the entire sample was very thoroughly stirred so as to insure a complete and uniform precipitation. The hardness and alkalinity were then tested for as above.

Turning our attention to the graph, it will be noticed that the hardness of the water decreased uniformly after each charge until the hardness of 7.0 deg. was reached, which is the minimum that can be obtained with lime alone. Upon further charging, the hardness increases uniformly but much more rapidly.

The hardness curve may be explained as follows: The hardness decreases uniformly as long as the chemical action between the lime and raw water takes place. When this chemical action is complete the water is at its minimum hardness and any further addition of the lime tends only to introduce an excess of this reagent and increase the hardness and alkalinity of the water.

This conclusion is substantiated when an examination of the alkalinity curve is made. No alkalinity is observed until the second charge, after which the alkalinity rises uniformly until the minimum hardness is reached, then the alkalinity increases at a greater rate, owing to the excess free lime.

The results of this test were calculated to pounds of lime per 1,000 gal. of raw water to make them of more value to the engineer. Table I will show the amount and the effect of each addition.

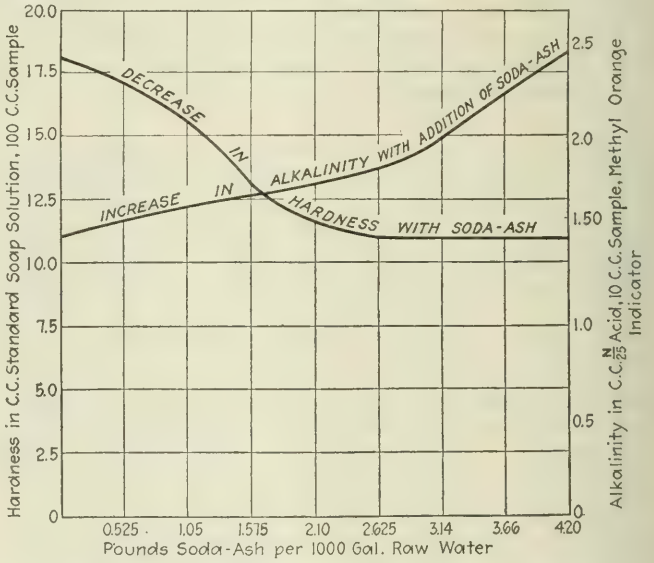
TABLE I. EFFECT OF LIME (CaO) UPON RAW WATER

Lb. Lime per 1,000 Gal. Raw Water	Hardness in c.c. Standard Soap Solution	Alkalinity in c.c. N/25 Acid Phenolphthalein as Indicator
0.0	20.0	None
0.52	17.5	None
1.05	15.0	None
1.57	12.5	0.08
2.10	10.0	0.20
2.62	7.5	0.30
2.91	7.0	0.36
3.14	7.5	0.43
3.66	10.5	0.58
4.20	13.5	0.75
4.72	16.0	0.93
5.25	19.5	1.13

The results of this experiment may be summarized as follows: Sufficient lime should be added to cause the chemical action between the lime and raw water to go to completion, but an excess of this reagent is to be avoided, as it will increase the hardness and alkalinity very noticeably.

Test II. Effect of Soda Ash (Na_2CO_3) Upon Raw Water

A second experimental run was made with 30 gal. of raw water, using successive charges of soda ash. The soda ash was added as a solution by mixing each charge with some of the water of the original sample. After each addition the sample was mixed and tested for



Hardness in C.C. Standard Soap Solution, 100 C.C. Sample
Alkalinity in C.C. N/25 Acid, 10 C.C. Sample, Methyl Orange Indicator
DECREASE IN HARDNESS WITH SODA-ASH
INCREASE IN ALKALINITY WITH ADDITION OF SODA-ASH
Pounds Soda-Ash per 1000 Gal. Raw Water

CHANGE OF HARDNESS AND ALKALINITY WITH ADDITION OF SODA ASH

hardness and alkalinity, as in the lime experiment, excepting that methyl orange was used as the indicator.

Turning our attention to the accompanying graph, it will be seen that the hardness decreases rapidly after each successive charge until the minimum of 11.0 deg. is reached. This is the minimum that can be obtained with the use of soda ash alone, and marks the point at which the chemical action between the soda ash and raw water is complete. Further addition of soda

sh produces no change, serving only to introduce an xcess of the reagent and consequently increasing the kalinity. An excess of soda ash is not to be feared, s apparently it has no effect on the hardness of the ater, although it does increase the alkalinity.

Turning our attention to the alkalinity curve, we see iat the alkalinity increases uniformly until the mini-ium hardness has been reached, after which the sud-en upward trend of the curve tells us that an excess f the reagent has been introduced and that no more oda ash need be added.

The results of this test were then calculated to pounds f lime per 1,000 gal. of raw water in order to make them iore convenient for the engineer to follow. Table II ill show the amount and the effect of each addition of ie reagent.

TABLE II EFFECT OF SODA ASH (Na_2CO_3) UPON RAW WATER

Lb. Soda Ash per 1000 Gal. Raw Water	Hardness in c.c. Standard Soap Solution	Alkalinity in c.c. N/25 Acid Methyl Orange as Indicator
0.0	18.0	1.45
0.52	16.0	1.55
1.05	15.5	1.65
1.57	13.0	1.70
2.10	11.5	1.75
2.62	11.0	1.85
3.14	11.0	2.00
3.66	11.0	2.25
4.20	11.0	2.43

The results of this experiment may be summarized s follows: Sufficient soda ash should be added so that slight excess of this reagent remains after the chem-cal action between it and the water has been completed. The excess will have no effect upon the hardness and ut little effect on the alkalinity, so that the engineer eed have no fear of its presence. This excess will rove of great value in case the raw water varies in nitial hardness, as such small fluctuations can be read-ly cared for by this reagent.

Test III. Effect of Lime and Soda Ash Upon Raw Water

We have heretofore discussed the effect produced by he addition of lime and soda ash with regard to each urve separately, and now we will discuss the effect of the addition of both soda ash and lime together pon a sample of raw water.

We have found that the addition of lime to raw water roduces a minimum hardness of 7.0 deg. by precipita-ing the soluble hardness-forming salts of magnesium nd lime, but other salts of these elements still re-nain in solution and cannot be removed by lime but will e removed by soda ash.

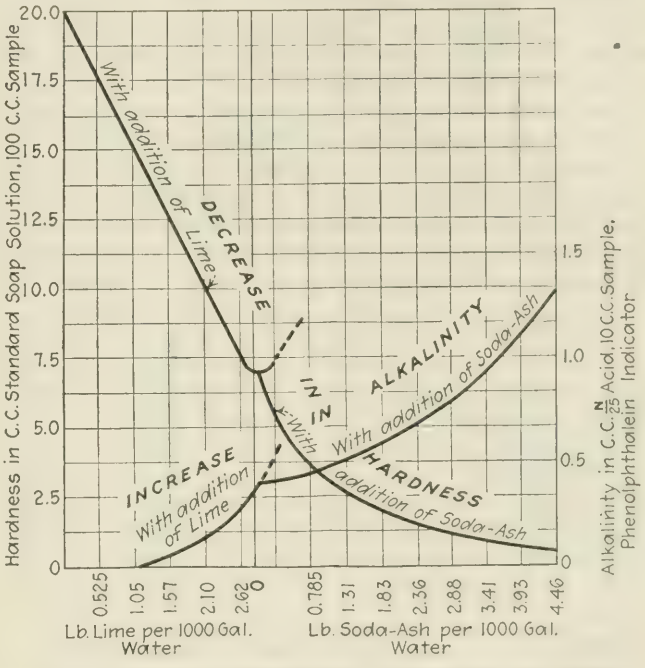
Now the addition of soda ash to raw water produces a minimum hardness of 11.0 deg. by removing to some extent the hardness-forming salts of lime and magne-sium, but other salts of these elements still remain in solution and cannot be removed by soda ash, but will be removed by the addition of lime.

Now it is obvious that by adding both reagents in their proper proportions, theoretically all the hardness-forming salts would be removed and an ideal water result. This is the experiment which will now be car-ried out to test the value of the theory.

A 30-gal. sample of raw water was obtained as in the preceding experiments and treated with sufficient lime to produce the lowest possible hardness obtainable with lime alone. This datum was obtained from the lime-water graph. Lime was added first instead of soda ash because an added excess of lime will be cared for by the addition of soda ash later on. The mixture was thoroughly stirred and allowed to set for some time. Upon testing we found that the water had dropped from a hardness of 20.0 deg. to one of 7.0 deg. Now successive charges of soda ash were added, as in the soda ash experiment, and the mixture thoroughly stirred after each addition and a sample taken to be tested as in the previous tests.

Turning our attention to the hardness curve, we find that the hardness decreases rapidly with the successive charges until the minimum of 0.5 deg. is reached, after which no further decrease is obtainable. The theoretical hardness of 0.0 deg. is not obtainable, being probably due to the small sample of water originally treated. In the water-softening system in operation at our plant it is nothing unusual to obtain a hardness of 0.0 degree.

Turning our attention to the alkalinity curve, we find that the addition of soda ash retarded the upward trend of the alkalinity, as indicated by the dotted line, and caused it to rise more slowly until at the minimum



CHANGE WITH CONSECUTIVE ADDITIONS OF LIME AND SODA ASH

hardness the alkalinity is 1.3 deg. This action of the soda ash upon the lime-treated water is very well illustrated in the combination curves which are graphically presented. For instance, an examination of the hardness shows the downward trend of the curve until the minimum hardness due to lime alone has been reached; the dotted curve shows the results of further addition of this reagent. The soda ash begins where the lime has left off and takes the hardness down to its minimum of 0.5 degree.

The same is true of the alkalinity curve. Upon the addition of lime the curve takes a rapid upward trend until the addition of soda ash, when its upward trend is decidedly retarded and a more gradual rise takes place. Table III shows the amount and effect of each addition of lime and soda ash upon raw water.

TABLE III. SHOWING QUANTITIES OF LIME AND SODA ASH IN COMBINATION CURVE

Charge in Lb. per 1,000 Gal.	Hardness in c.c. Standard Soap Solution	Alkalinity in c.c. N/25 Acid
	LIME	
0.00	20.00	0.00
0.525	17.50	0.00
1.05	15.00	0.00
1.57	12.50	0.066
2.10	10.00	0.13
2.63	7.50	0.25
2.93	7.00	0.40
	SODA ASH	
0.00	7.00	0.40
0.26	5.25	0.41
0.0785	3.00	0.43
1.31	2.50	0.50
1.83	2.00	0.58
2.36	1.50	0.66
2.88	1.00	0.76
3.41	0.75	0.92
3.93	0.65	1.09
4.46	0.50	1.30

The Analysis of Water

As before stated, all water contains soluble impurities to some extent, and, since the removal of these salts is the chief question in the production of boiler-feed water, a knowledge of which salts and the quantity of each is of the greatest importance in determining the amount of precipitating reagents to be used. This knowledge is secured from the analysis of the raw water. By this means the amount of precipitant can be regulated with accuracy.

The table below gives a complete analysis of the water with a hardness of 20.00 before treatment, and of the same water with a hardness of 0.50 obtained in the combination lime and soda ash experiment. The analysis as outlined in Stillman's Engineering Chemistry was followed. The quantities of salts are figured in grains per U. S. gallon.

	Raw Water	Treated Water
Hardness	20.00	0.50
Alkalinity with phenolphthalein	None	1.30
Silica	0.35	0.35
Oxides of iron and alumina	Trace	Trace
Calcium carbonate	10.04	1.52
Magnesium carbonate	5.71	None
Sodium carbonate	None	0.23
Calcium sulphate	2.72	None
Sodium sulphate	None	3.89
Magnesium chloride	0.42	None
Magnesium hydrate	None	0.39
Sodium chloride	1.87	1.58
Sodium hydrate	None	0.82
Volatile and organic matter	0.60	0.15
Total solids	21.41	8.93

Influence of Impurities in Lead on Its Resistivity to Acid

C. E. Barrs stated in a paper presented before the December, 1919, meeting of the London Section of the Society of Chemical Industry that lead which contained 0.002 per cent of copper was attacked at 250 deg. C., whereas a sample which withstood strong acid up to 296 deg. was found to contain 0.021 per cent. He concluded that the most satisfactory percentages of copper as regards increasing the resistance of lead to the action of hot acids lay between 0.002 and 0.05 per cent, such lead being able to withstand corrosion up to 280 deg. In the discussion that followed Mr. Lancaster stated that a really pure lead, quite free from copper, will withstand the action of strong sulphuric acid up to 300 to 310 deg. C.

Legal Notes

By Wellington Gustin

Contract Prohibiting Presence of a Given Substance in Ore Does Not Imply Exclusion of Others

PLAINTIFF brought action to recover for the breach of contract by defendant for the purchase of 150 tons of antimonial lead. On affirming a judgment for the plaintiff the Appellate Court held that where defendant contracted to purchase of plaintiff certain "Newark antimonial lead, running approximately from 15 per cent to 18 per cent antimony and not above 1 per cent arsenic," and accepted a certain quantity shipped but refused to accept further shipments unless they were found to be absolutely free from copper, and defendant's witnesses testified no antimonial lead is produced "absolutely free of copper," and there was no evidence that the amount of copper supposed to be in the antimonial lead was sufficient to impair its value or render it unsuitable to defendant's purposes, then defendant's refusal to accept shipments unless found to be absolutely free from copper constituted a breach of the contract for which the plaintiff would be entitled to recover.

Ruling on the effect of a provision in a contract as to the prohibition of a given substance in ore, the court said that the expression in a contract of prohibition against the presence of a given substance in ore sold would, under ordinary canons of construction, exclude any implied exclusion of any other substance. (American Metal Co. vs. U. S. Reduction Co., 205 Ill. App., 492.)

Factory Refuse—What Is Held to Be Polluting Matter—Public Health Paramount

In a suit to enjoin violation of a statute providing that polluting matter shall not be discharged into any stream or suffered to remain upon the banks thereof above the point where a municipality obtains its water supply, the Chemical Co. of America, Inc., was not permitted to plead that the pollution is not perceptible at the municipality involved, because of mitigation in quantity and quality of the effluent; nor that the polluting matter is harmless as diluted, nor that the municipal inhabitants would suffer no inconvenience were their filtration plant of an up-to-date type and properly managed. Nor is it a defense, under the statutes, said the court, that the pollution cannot be traced to spigots in the municipality, the pollution aimed at by the law being at the point of discharge into the stream. (State ex rel. Department of Health of New Jersey vs. Chemical Co. of America, Inc., 107 Atl., 164.)

The Charge Against Defendant

In this action the defendant was charged with discharging factory refuse into the Rahway River, and of depositing such refuse on the river bank above the point from where the city of Rahway takes its water supply, in violation of the statute which provides that "no excremental matter, domestic, factory, workshop, mill or slaughterhouse refuse, creamery or cheese factory waste, garbage, dyestuffs, coal tar, sawdust, tanbark or refuse from gas houses, or other polluting matter" shall be discharged into any river, stream, etc., or placed or suffered to remain upon the banks thereof, above the point from which any municipality obtains its supply of water for domestic use.

Defendant's chemical plant is located at the confluence

of two streams called north and south branches, which empty into the Rahway River about five miles above the Rahway intake. All the liquid waste of the factory was emptied directly into the south branch until 1917, when the municipality of Rahway objected. The chemical company then took measures to clarify the refuse by eliminating the more objectionable matter, the solids, and to store and retain the effluent upon its own premises. Elevated settling basins were installed, and a lagoon was constructed, and later a second and connecting lagoon, into which the effluent from the settling basins is discharged. These remedial steps were taken after consultation with the State health officials and apparently with their approval. However, the progress made and methods pursued were unsatisfactory to these authorities and before the completion of this work the Attorney General of New Jersey asked for an injunction against this alleged pollution.

Tolerated During War Work

From the facts in the case it appears that pollution of the stream was established at a hearing in May, 1918, but as it was not appreciable at Rahway and the defendant was furnishing the Federal Government with an exclusive product for the prosecution of the war, the injunction was withheld at that time. However, the case was retained, with leave to bring the matter on for further hearing if the dike and other devices then under construction failed of their object. After the armistice the State brought up the cause for further hearing, complaining that the efforts of the chemical company to abate the pollution were futile. At that time the dike of the outer or second lagoon had been finished; a moat, of a depth lower than the lagoons and skirting the dike, was dug and connected to sumps, or catch-basins, to intercept seepage, and the sumps were fitted with automatic pumps to force the seepage back into the lagoon. More than that, it appears that before this second hearing came to an end the bed of the south branch was filled up and the stream diverted, so that its nearest point to the lagoon was 150 ft. away, and scientific experiments to neutralize the effluent were under way.

Polluting Matter Seeps Through Lagoon Walls

The court said despite this earnest endeavor the lagoons were not watertight, and some of the waste contents still leaked into the streams, polluting them, though perhaps not noticeable or even chemically discoverable at Rahway. A part of the wall of the first lagoon is made up of a pervious railway embankment through which the liquid seeps and runs into the north branch. Other evidences pointed to a time, sooner or later, when the effluent will find an outlet in the new stream bed. That the refuse, the wash of chemical compounds, is deleterious to health and objectionable because of odor, taste and discoloration is proved by the fact that all fish life in the immediate vicinity of the factory was destroyed during the first years of operation of the plant when the flow of waste into the streams was unrestrained.

Plea Not Good That Pollution Was Not Perceptible

Said the court, it was not a good plea that the pollution was not then perceptible at Rahway, nor that the more obnoxious of the polluting matter is nitrobenzol, which to taste and smell is likened unto oil of bitter almonds and sometimes used by bakers as its substitute, or that it is benzaldehyde; nor that to take a poisonous dose one would have to drink more of the water than would be required to drown in. These defenses might be of value were the case one of suppression of a common-law nuisance, but this suit was in aid of the police power of the State and such defenses were wholly beside the issue.

In the amendment of 1918 the Legislature determined that factory refuse and the other mentioned wastes and cast-offs are contaminating, and peremptorily forbade their discharge into streams and their deposit upon the banks thereof. The defendant was violating the law in both of these aspects, said the court. There was drainage of the refuse into at least one of the streams and it matters not if it cannot be traced to spigots in Rahway. The pollution aimed at by the statute law is at the point of discharge into the stream. Further, it condemns not only actual pollution but pronounces as imperatively against the threat and menace of it upon the banks of the streams.

Storing of Liquid Waste on Banks of Stream a Standing Menace

The vast body of liquid waste stored on the banks was a standing menace, the court said. The lagoons cover about five acres and the average depth of the liquid content about 2½ ft. Overflows after heavy downpours of rain, breaks in the dikes from wash or lateral pressure, wastage through fissures in the lagoons, are ever threatening dangers. Then there was seepage at various places in the dike, and other possible dangers. In the circumstances, the confidence expressed by the defendant that it could successfully retain the refuse in the lagoons, and its assurances that it will do so, to the immunity of the water, could not be considered, said the court.

The court also said that the legislative scheme to purify the waters of streams embraced two specific avenues of pollution. One was the discharging of polluting matter directly into the stream, which must include the placing of it on the bank where it must necessarily fall or flow into the stream, and the other was the depositing of it so near the banks as to remain a menace of ultimately reaching the water, contaminating it. "It would be playing with words and trifling with legislative mandate to hold that discharges of polluting matter on the bank anywhere below the brink would be violative of the statute, while a deposit on the bank an inch away from the brink would not be." In another case cited it was then said that no doubt garbage dumps on lands immediately adjacent to the Delaware River, the refuse of which in normal times by reason of the natural slope of the ground found its way into the waters of the river, violated the provisions of this statute.

Good Faith of Company Not Questioned

In granting the injunction against the chemical company preventing the discharge of its factory refuse into either of the branches of the river and the suffering of such factory waste to remain on the banks of these streams, the court said that the company had assiduously and in good faith sought to abate the pollution; and as it had prospects of neutralizing the waste, it ought to be given reasonable opportunity to develop the treatment.

This was done, but the costs of the action were put upon the company.

Recovery of Pyridine From Byproduct Coke Ovens*

By F. E. Dodge and F. H. Rhodes

Among the comparatively less important components of coal tar are the so-called "tar bases," pyridine, quinoline, isoquinoline, and their homologues. These tar bases are formed during the coking process, either as primary products from the thermal decomposition of the coal substance or as products of secondary reactions occurring in the gases. When the coal tar is distilled, most of the pyridine and its lighter homologues come over with the light oil fraction; while quinoline, isoquinoline, and the higher homologues of pyridine are concentrated in the carbolic oil. By extracting these oils with moderately dilute sulphuric acid, separating the resulting pyridine sulphate solution from the oil, and liberating the tar bases with an alkali, the crude tar bases may be obtained. From the crude bases pure pyridine or "commercial pyridine" of various grades may be prepared by further purification and rectification. It may be noted in passing that the term "pyridine," as used commercially, is applied, not only to true pyridine (C_5H_5N), but to all of the various tar bases, in somewhat the same way that the term "benzols" is used to include all of the simpler homologues of benzene.

Until fairly recently the supply of pyridine from the coal tar oils, although comparatively small, was sufficient to supply the demand. However, the growth of the American chemical industries which has taken place within the last few years has developed new uses for the pyridine bases, and has greatly increased the amounts required for the purposes for which they were formerly used. The development of the dyestuff industry has created a demand for anthracene and carbazole, and in the purification of each of these products pyridine is used. Light pyridine as a denaturant for alcohol is being introduced to some extent into this country; and some grades of tar bases are finding application as solvents for certain industrial processes. Moreover, recovery of pyridine bases from tar oils is a rather costly process and the pyridine thus obtained is so expensive as to prohibit its use for some purposes for which it would otherwise be suitable. Finally, the tar bases obtained from oils consist largely of "heavy pyridine" (quinoline, isoquinoline, etc.), for which only a comparatively slight demand exists, and contain relatively little of the more valuable light pyridines. In view of these facts it became evident that a larger and less expensive source of light pyridine bases must be developed if the increasing demand was to be met.

Coke Oven Investigation

In the development of new sources of pyridine the first problem which presented itself was the determination of the amount of pyridine in the coke oven gases which escaped condensation with the tar. In view of the fact that the lighter pyridine bases have distillation ranges somewhat corresponding to those of benzol, toluol, and solvent naphtha, it appeared probable that a considerable amount of the pyridine formed during the coking was not condensed either in the hydraulic main or in the tar separators, and it seemed logical to expect that a considerable amount of this pyridine would be absorbed and retained by the acid liquor in the ammonia saturators. Accordingly an investigation of the pyridine balance for the ammonia saturators in a byproduct coke oven plant was undertaken. This work was done by Mr. Dodge and Mr. Rhodes at the plant of the Toledo Furnace Co., at Toledo, and by Mr. Dodge and Mr. Warner at the Clairton byproduct coke plant of the Carnegie Steel Co. At each of these plants Koppers byproduct coke ovens were used. Tar and some ammonia water is condensed in the usual way by passing the gases through hydraulic mains, primary coolers, and tar extractors. Tar-free gas is then reheated slightly and passed through the ammonia saturators, in which the gas is forced to bubble through a saturated solution of ammonium sulphate containing 6 to 10 per cent of free sulphuric acid. Ammonia-free gas is then passed to benzol scrubbers and finally to distributing mains. In the ammonia saturators ammonium sulphate is formed and precipitated from the solution and the solid ammonium sulphate is continuously removed and separated from the mother liquor by centrifuging, while the sulphuric acid concentration of the bath is continuously maintained at the desired point by the addition of the fresh acid. The installations at the two plants were essentially similar, there being only slight differences in form of the individual pieces of apparatus and only minor differences in the operation.

This work showed that a very considerable amount of the pyridine bases formed during the coking of the coal is not condensed with the tar but passes through the primary coolers and tar separators and is absorbed by the acid solution in the ammonia saturator baths. The work showed also that the pyridine sulphate thus formed remained in solution in the saturator bath liquor until the concentration of pyridine sulphate in the liquor reached a certain point, and that further absorption of pyridine by the bath liquor containing more than this critical amount of pyridine sulphate resulted in the separation of a portion of the pyridine sulphate with the ammonium sulphate crystals. For example, it was found that no pyridine could be detected in the salt from a bath containing 2.5 per cent pyridine and that the pyridine contained in a salt from a bath containing 7.5 per cent pyridine was almost one-quarter per cent. The work done at the coke ovens also showed that the amount of pyridine bases not condensed with the tar amounted to approximately from one-tenth to one-eighth of a pound per ton of coal coked.

On the basis of these results it was calculated that the total production of pyridine bases available from coke ovens which are operating in the United States and which use the semi-direct sulphate process is approximately 446,000 gal. per year.

Method of Separation

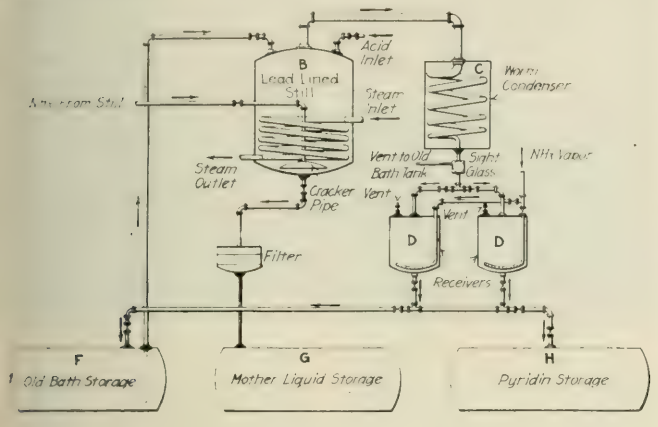
Because of the relatively small amount of bases present in the bath liquor at any one time, and because of the large loss of pyridine which occurred when the concentration of pyridine sulphate in the bath was allowed to rise above a certain very low point, it was evident that any process which would prove economically practicable must not involve the use of expensive chemicals and must not interfere with the normal operation of the plant.

Further investigation showed that if the pyridine-containing mother liquor from the saturator bath is made alkaline by passing ammonia through it, the pyridine

*Read before American Institute of Chemical Engineers, Dec. 6, 1919, Savannah, Ga.

bases originally present in combination as pyridine sulphate are liberated and separate from the saturated ammonium sulphate solution as a distinct layer. It was found, moreover, that if the neutralization of the acid solution was effected rapidly by bubbling through it a gas rich in ammonia, the heat generated by the reaction was sufficient to bring the solution to its boiling point and to steam-distill off the pyridine bases as fast as liberated. On the basis of this work a process for the recovery of pyridine from the ammonia saturator baths was developed and a plant suitable for operating this process was designed and installed in connection with the byproduct coke oven plant at Toledo. The design of this plant is shown diagrammatically by the accompanying sketch.

Tank "F" is a large storage tank for holding the saturator bath liquor before treatment to recover the pyridine bases. This is provided with an outlet to the



hot drain tank, not shown, and with a discharge line leading to the pyridine still proper. "B" is a still in which the saturation of the bath liquor with ammonia vapor is effected. This still is lead-lined and is shown provided with a steam coil for heating the liquor (not found necessary in practice) and with an inlet line for the admission of ammonia vapor. Ammonia vapor required for saturating the bath liquor is taken from the ammonia still operated to concentrate the weak liquor that separates from the gas with the tar. The pyridine still itself is provided with a vapor pipe extending to the condenser and with a discharge line leading through a filter to the mother liquor storage tank. An acid inlet is also provided so that the final pyridine-free liquor may be acidified before being discharged. The mixture of pyridine vapor, ammonia, and water vapor coming from the pyridine still is condensed in the worm condenser "C" and the condensate is collected in receivers "DD," which are provided with discharge lines leading to the pyridine storage tank.

The operation of the plant is as follows: The ammonia saturators are run normally until the pyridine content increases to such a point that pyridine begins to appear in the solid ammonium sulphate as removed from the saturator. When this point is reached the saturator bath is discharged into the old bath storage tank "F" and a new bath is put in operation in the saturator. Sufficient of the material from tank "F" is then pumped to the pyridine still "B" to make a charge. The solution is saturated with ammonia vapor until strongly alkaline. The heat of reaction raises the charge to the boiling point and a mixture of pyridine vapor and water distills over, is condensed, and the condensate collects in the receivers. This condensate, as thus obtained, carries a considerable amount of water, and before this material is shipped or further worked up for pyridine it is desirable to remove as much as possible of this water. This is effected by agitating the material in the receivers with ammonium sulphate, adding approximately 1 lb. of solid ammonium sulphate for each gallon of distillate. The ammonium sulphate absorbs and is dissolved in the water and the resulting saturated solution separates to the bottom of the receiver, leaving an approximately dry pyridine as the upper layer. The ammonium sulphate solution is allowed to settle and is drawn off to the old bath storage tank, while the dry pyridine bases are drawn off to the regular pyridine storage tank.

It has been found that when the old saturator bath is made neutral or alkaline by the passage of the ammonia vapors a blue or bluish black precipitate is formed. This precipitate consists apparently of finely divided free carbon or of a mixture of free carbon with ferro- and ferri-cyanides of iron. In order to remove this precipitate the liquor from the still is filtered through a small filter. The filtered liquor is then stored in the mother liquor storage tank "G." This filtered, pyridine-free liquor may be charged directly to the ammonia saturators as a fresh saturator bath. We have found, however, that this filtered mother liquor may be used to very good advantage as a wash liquor for washing ammonium sulphate crystals in the centrifuges as they come from the saturator baths, since by using this liquor in this way it is possible to wash the crystals free from adhering impurities without incurring any danger of solution of the crystals.

It will be observed that this process involves a minimum amount of handling of various solutions. Moreover, no material is used which is not available in large amounts at any byproduct coke oven plant, and the process as outlined does not interfere in any way with the normal operation. Finally, the only materials which are used in this process are ammonia and sulphuric acid and all of the ammonia and all of the sulphuric acid thus used are recovered as ammonium sulphate by the normal operation of the plant.

The plant erected at Toledo was on a semi-experimental scale only and the production has not thus far been very large. However, several hundred gallons of pyridine bases have been produced at this plant and the results obtained appear to be very encouraging. The pyridine which has been produced has been essentially a crude, light pyridine, distilling very largely below 200 deg. C. The water content has varied considerably, although several of the lots have shown only a trace of water. This pyridine as produced appears to be a very satisfactory crude pyridine for the preparation of refined pyridine bases for denaturing and chemical purposes. The extension of this process to other and larger coke oven installations should afford a supply of light pyridine bases adequate to the present or the immediate future needs of the country.

Since the development of this process a new and very interesting aspect of its application to the byproduct coke oven industry has appeared. As is well known, the presence of pyridine is objectionable in sulphate of ammonia. The use of this pyridine recovery process in conjunction with the semi-direct ammonium sulphate process insures the absence of pyridine sulphate in the ammonium sulphate produced, which is very desirable from several points of view.

Electrical Precipitation in Japanese Smelters

By Dr. Ritaro Hirota and Kyoshi Shiga

A NUMBER of electrical precipitators have been installed in Japanese smelters since 1918 by the Metallurgical Research Institute, which owns the Japanese rights of the Cottrell process. These plants are all quite similar, consisting of from one-half to ten repeated sections, each containing sixty-four pipes, 12 in. in diameter and 16 ft. long (30.5 cm. x 4.9 m.) of cross-section shown in Fig. 1. Ordinarily one motor-generator set serves two sections, each set comprising a 15-hp., 50-cycle, 500-volt, three-phase motor, a 10-kva., 50-cycle, 200-volt generator, and a 10- or 15-kva. transformer capable of giving 100,000 volts on the secondary. Details of the various installations given below are taken from a pamphlet issued by the Metallurgical Research Institute.

Ashio Smelter, Furukawa Mining Co.

There were two treaters installed in 1918; one, which is called the main treater, was intended to treat the mixed gases from four McDougall roasters, two copper blast furnaces and four converters; and the other, called the reverberatory treater, was intended to treat the

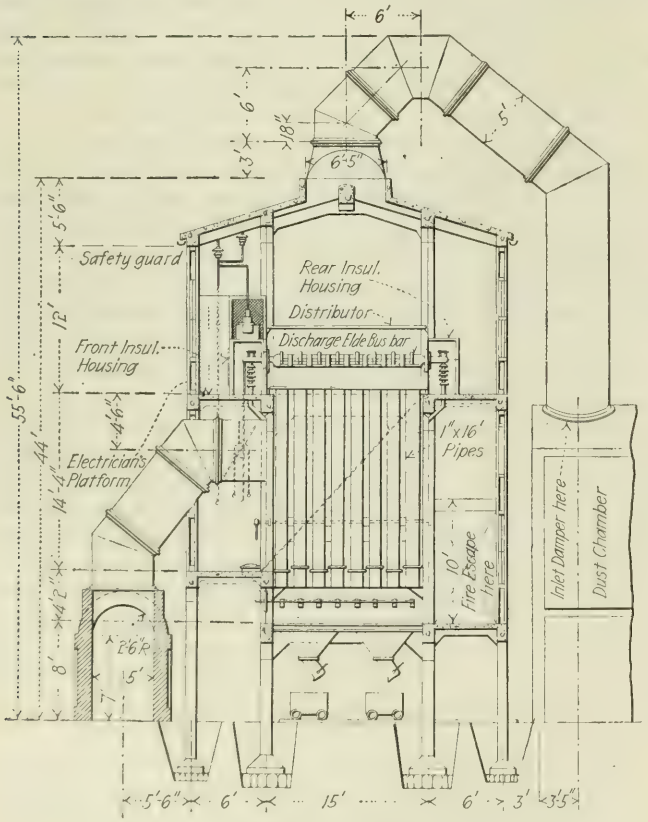


FIG. 1. ELECTRICAL PRECIPITATOR

gases from a reverberatory furnace after having passed through waste-heat boilers.

The gases are drawn through the main treater and discharged directly from the fan casings, while those of the reverberatory furnace are drawn through the reverberatory treater by the natural draft of the stack. As the reverberatory furnace is not operating continuously at present, the gases and those of eleven pot roasters, four blast furnaces and four copper converters are mixed and treated entirely by the main treater. Thus the gas volume now handled by the main treater seems somewhat in excess of 150,000 cu.ft. per min., as designed. The amount of dust collected varies from six to ten tons per 24 hr.[1] The efficiency of precipitation seems to depend upon the nature of the furnace charge and the moisture and temperature of the gases treated. When the conditions are very favorable, it runs as high as 98 per cent, passing a white smoke, but sometimes it drops to about 70 per cent, when the smoke acquires a yellow tint. When the conditions are such that the charging voltage can be raised above 80,000 volts with a comparatively small increase of the current, precipitation is very satisfactory.

Several years ago a large dust chamber was installed, using the Roesing wire system. The gases passed from this chamber to four large stacks, in which they were diluted by the forced admission of fresh air, before being discharged into the atmosphere. The main treater was installed at the side of this dust chamber, so the gases pass through the dust chamber before going through the treater. The numerous suspended wires in the dust chamber were removed, so that only the heavier dust, which is of more value because of its higher percentage of metals, would be caught in the chamber and all the lighter dust which cannot be efficiently collected by gravity settling would be caught in the Cottrell treater.

An analysis of one of the samples of the Ashio main treater precipitate is as follows:

	Per Cent		Per Cent
Cu	1.37	Al_2O_3	1.45
Fe	2.99	As	31.33
S	19.72	Pb	0.84
SiO_2	3.92	Zn	5.57
CaO	1.19	Moisture	6.40

As the analysis shows, the precipitated dust contains rather large quantities of the oxides of arsenic. These oxides are extracted by subliming the dust in a small reverberatory furnace, and the cinders resulting, which are quite rich in copper, are sent back to the pot roasters after being briquetted.

Kamioka Smelter, Mitsui Mining Co.

The gases passing through the treater come from the following furnaces: Three lead-smelting blast furnaces, two liquation furnaces, five softening furnaces, and all the lead-refining furnaces and kettles. The Kamioka Smelter is located in the heart of the sericulture district, and the residents in the vicinity made strenuous objections and demanded heavy indemnities, claiming that the smelter smoke damaged the mulberry leaves and killed the silkworms. Therefore, every effort was made to complete and start the Cottrell plant at an early date. About 1 to 1½ tons of dust are collected per day in a three-section treater.

Analysis of the precipitate is as follows:

	Per Cent		Per Cent
As	19.65	Free S	1.13
Pb	57.26	SO_4	0.63
Cu	Trace	Zn	1.68
Bi	0.16	Ag	0.0063
Fe	0.16	Au	Trace
Total S	5.91	Insol. residue	0.31
		Moisture	0.90

Naoshima Smelter, Mitsubishi Mining Co.

The erection of this smelter was permitted by the government on the condition that the smelter gases would be cleaned by the Cottrell process. The operation of the treaters (Fig. 2) was therefore begun when

[1] Long tons—approximately equivalent to metric tons—are used throughout this paper.

the smelter started up in March of 1919. It was designed for a capacity of 80,000 cu.ft. per min. (2,300 cu.m. per min.), assuming a velocity through the pipes of 5 ft. (1.5 m.) per sec. The lead-bearing fumes from the lead-smelting furnaces and the fumes from the McDougall roasters and converters of the copper smelter are mixed, and are both treated by the precipitator. Natural draft is furnished by a stack 150 ft. high and 10 ft. inside diam. (45.7 x 3.05 m.).

The smelter being only recently started, the furnaces are not yet running at their full capacity and the gas

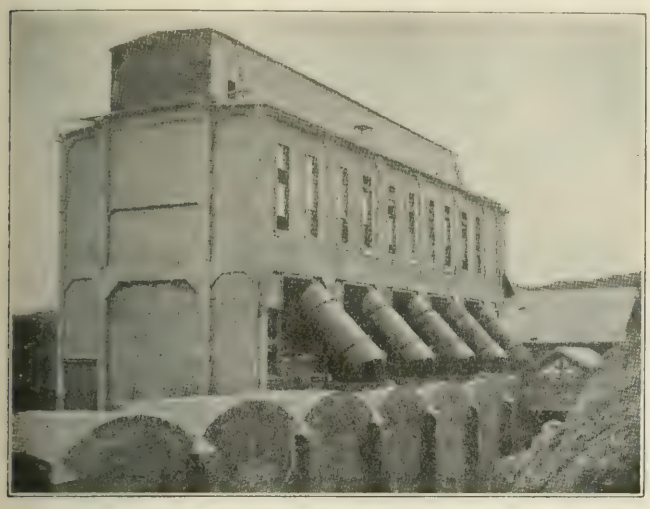

FIG. 2. TREATER AT NAOSHIMA SMELTER

volume handled runs from 40,000 to 45,000 cu.ft. per min. (1,100 to 1,300 cu.m.) Visual clearance by an S-section plant is practically perfect.

The dust collected every 24 hr. amounts to about 1.5 tons, and its analysis is as follows:

	Per Cent		Per Cent
Cu	2.30	Sb	3.14
Pb	22.54	Zn	3.29
Fe	11.20	Loss on heating	25.68
S	12.00		G/Ton
As	13.43	Ag	100
Au	Trace		

IKUNO SMELTER, MITSUBISHI MINING CO.

The treater at the Ikuno Smelter handles the gases from two blast furnaces smelting copper ores. After passing through an old dust chamber, the gases are drawn through the treater by an exhaust fan and are discharged from the old stack. At the first trial the treater showed good efficiency, but this lasted only a couple of days and then the operation became so unsatisfactory that the diminution of smoke could scarcely be recognized even when the treater was charged with a high potential. After experimenting in various ways, it was decided to humidify the gases, a practice which was found necessary for satisfactory precipitation in several American plants. A dozen orchard spray nozzles of $\frac{1}{16}$-in. diameter (1.6 mm.) arranged in the dust chamber using water at 120 lb. pressure per sq.in. (8.4 kg. per sq.cm.) injected a fine spray into the gases before they entered the treater. Thus precipitation was conspicuously improved and the efficiency raised to about 95 per cent, and at the same time the operator can raise the charging voltage to 80,000 volts while the current is only 30 amp. When, in order to examine the effect upon precipitation, the water sprays are turned off, the charging potential drops and the current increases so that the clearance becomes as low as 50 per cent.

The amount of dust precipitated per 24 hr. is about 0.6 ton, and its analysis is as follows:

	Per Cent		Per Cent
Ag	0.0007	As	32.39
Pb	7.80	Sb	Trace
Cu	0.50	Sn	10.80
Bi	2.48		
Fe	1.01	SiO_2	1.05
Al_2O_3	0.20	S	12.17
Zn	6.80	SO_4	6.78
CaO	0.30	H_2O	5.40
MgO	Trace	C, etc.	12.32

NIKKO ELECTROLYTIC COPPER REFINERY, FURUKAWA MINING CO.

Here the gases from two cupellation and two reduction furnaces are treated to recover silver-bearing lead dust. The treater consists of one section of 32 pipes, arranged in a rectangle 8 x 4.

The treater was started in May, 1919. The analysis of the precipitated dust is as follows:

	Per Cent		Per Cent
Au	Nil	Pb	54.90
Ag	0.6896	Se	14.23
Cu	0.23		

The amount of the precipitate is about 100 lb. (45 kg.) per 24 hr. The power consumption is comparatively high, being from 2.5 to 5 kw.

Scottish Oil-Shale Possibilities

H. M. CADELL read a paper before a recent meeting of the Mining Institute of Scotland in which he discussed the origin of their important oil-shale beds. He said that all really competent authorities were at one in ascribing mineral oil to an organic source in the shape of vegetable or animal remains embedded in certain strata, the decomposition of which had produced solid or liquid hydrocarbons or natural gases. The origin of the oil in the shales had been explained in two ways.

ORIGIN OF OIL SHALES

The most natural explanation is that the shales were originally beds of fine silt or clay, deposited in lakes or lagoons near the shores of a carboniferous land area, and the impalpable mud was mixed with a large quantity of vegetable or animal matter, like the black vegetable slime that was washed off a peat moss. During the carboniferous period vegetation was luxuriant, and there were both forests and peat mosses, the debris of which might easily be washed away and deposited in the adjacent lagoons round the coast, or in land-locked basins where the water was tranquil. The vegetation mud in the oil shales formed a more or less uniform impervious stratum, and each seam originally covered a wide area—more than 100 sq.mi. in extent. The uniformity in composition and the extent of the shales was remarkable, and could only be explained by a long-continued deposit of fine silt under steady conditions of climate and topography.

ANOTHER THEORY

The second of the theories supposed that the shales were not originally petroliferous at all, but were merely receptacles of oil that had been injected or "inspissated" into them in some manner from some oil-bearing reservoir in the vicinity. However, so-called oil shale does not contain oil or oil matter at all. It contains a substance called kerogen, which is not oil or bituminous in nature, but at once turns into oil when heated to a certain temperature. In some cases the shales have been invaded

by igneous rock, which had once been hot enough to raise them to the temperature that would distill the kerogen and produce oil on the spot, but except at such places the kerogen remains unaffected. It appears obvious that the igneous invader had not an excessive temperature, because in most cases the surrounding rocks, if affected at all, show only the effects of the heat for a few feet or inches from the edge of the whinstone mass. The Scottish shalefields are therefore in more likelihood a potential oilfield that had been arrested in its infancy for want of the kindly warmth in Mother Earth that was required to turn kerogen into liquid hydrocarbon, but which had produced the finished article in more favored locations.

Estimates of Oil-Shale Resources

Other interesting material on the same subject is abstracted in the *Iron and Coal Trades Review* for Oct. 24, 1919, from the 1918 "Summary of Progress of the Geological Survey," containing a series of estimates of the oil-shale resources. In preparing these, all substances except oil-shale have been excluded, though oil can be obtained, and has been produced in Scotland on a small scale from cannel coal, torbanite or bog-head, parrot coal and parrot shale, peat and ironstone coal. As regards the thickness and quality which render a shale workable, it was decided to adopt as a standard the conditions which existed in the Scottish oil-shale industry during the ten years preceding the war. Accordingly, shales less than 3 ft. in thickness have been excluded, except in a few cases where their high quality or other favorable conditions have proved them to be of practical value. Also those areas have been excluded where the oil-shale, though present, is known to be of no practical value.

A rough approximation only to the amount of oil likely to be obtained from the oil-shale reserves by distillation is possible. A shale yielding a large quantity of ammonium sulphate can be distilled at a profit, even though it produces only 19 gal. of crude oil per ton. The richest shales yield 60 or 70 gal. per ton. In the Reports of the Mining Inspectors of recent years, 25 gal. of oil per ton is given as the average figure.

As regards depth, 300 fathoms (1,824 ft., or 556 m.) has been taken as the present limit, for it happens, from the geological structure of the shale-fields, that the oil-shale resources below that depth are not large and would not greatly affect the totals obtained. Moreover, there are no bore-records which can serve as reliable indications of the occurrence, thickness and quality of these deep-seated shales. The limit has hardly been reached by the deepest shale mines.

Considerable Number of Shale Seams Worked

The number of shale seams that have been worked in Scotland is considerable. Nearly all of them lie below the Scottish carboniferous limestone. The principal shales are, in downward order, the Raeburn, Mungle, Fells, Broxburn, Champfleurie, Dunnet, Camps, and Pumpherston shales. Of these seams, the more important, such as the Broxburn, Dunnet and Pumpherston, may form a series many feet in thickness, which is separated into bands of good oil-shale with barren shale or blaes between, and each band may have a separate designation. In no district are all the shales present in workable development: often at the horizon of an oil-shale only a carbonaceous shale or shaly blaes is met with. The horizon is generally recognizable in the bores by the presence of some equivalent bed, or the oil-shale may be there but too thin to work. Oil-shales seem to be much more variable than coal seams in these respects. It is noteworthy also that they do not pass laterally into coal seams, but into dark carbonaceous shales yielding little oil.

Each of the important oil-shales is confined, as regards its maximum development in thickness or quality, to one or more areas, and in no one area is it usual to find more than three or four of the oil-shales in satisfactory condition. The numerous masses of intrusive igneous rock that have been injected into the oil-shale measures of the Lothians have destroyed a vast quantity of oil-shale by a process of subterranean distillation, and unfortunately the principal oil-shale seams—the Broxburn, Dunnet, and Pumpherston—have all been extensively subjected to this action.

Future of Scottish Shale-Oil Mining

Other factors, not geological, affect the estimates of workable reserves. A shale that was unworkable before the war may, by changed commercial conditions, prove to be of value. As an example, the Pumpherston shales, which are comparatively poor in oil but rich in ammonia, were once practically valueless, but now are of great importance. The future of shale-oil mining in Scotland would seem to depend principally on two factors—the rates of wages and the prices obtained for shale-oil products (oil, paraffine wax, and sulphate of ammonia)—and any changes in these will directly affect the magnitude of the payable reserves of oil-shale.

Since 1873 the output of the oil-shale from Scottish mines has been reported each year in the Home Office returns. From 1873 to 1917, inclusive, it amounted to 89,401,981 tons, or, say, 90,000,000 tons.[1] The rise of Scottish oil-shale mining dates approximately from 1862, when the Torbanehill mineral was exhausted, and an allowance of 10,000,000 tons is more than sufficient to cover all mining before 1872 and also the output for 1918 (not yet published). This gives 100,000,000 tons as approximately the amount of shale that has been mined. To this must be added the amount lost in working from a variety of causes, say in the neighborhood of 20 per cent, or 20,000,000 tons; giving a total of shale mined 120,000,000 tons.

Reserves and Present Output

The estimated reserves for the oil-shale fields are as follows:

	Proved and Probable, Tons	Possible, Tons
Midlothian	163,497,000	356,120,000
Linlithgowshire	416,539,000	371,211,000
Lanarkshire	16,730,000	67,000,000
Peebles-shire	5,120,000	28,020,000
Fifeshire	.....	61,440,000
	601,886,000	883,791,000
Deduct amount already worked as above	120,000,000	
Total still available	481,886,000	

Practically all areas where igneous intrusions are known to occur on or near the horizon of an oil-shale have been omitted from the estimated reserves.

At present the output is approximately 3,000,000 tons a year. Adding 20 per cent for loss in working we get 3,600,000 tons as the yearly depletion of reserves. This indicates 133 years as the duration of these proved and probable reserves at the present rate of working.

[1] A metric and long ton are practically equal.

Air Conditioning in the Industries

By E. E. Leason

AIR conditioning is becoming recognized as a subject of increasing importance by those who are interested in atmospheric conditions in factories, mills, laboratories, bakeries, tanneries, and the like, because the proper conditioning of air not only aids manufacturing processes but gives employees the proper air to breathe.

The possibilities of overcoming unhealthful air conditions are multitudinous. Among the most pronounced examples are chemical laboratories, bakeries, confectionery factories, film manufacturers' laboratories, lithography and printing plants, textile mills of all classes, and hide and leather establishments. The possibilities, however, of conditioning air are by no means confined to the industries just enumerated. Wherever there is "sick" air there is a remedy.

Specific Examples

To be more explicit about the application of air conditioning systems, a few specific examples may be considered. For instance, in dye houses where no air conditioning system is installed the amount of fog or steam may be so great that a light will not show through it more than 30 in. away. The drip from the roof in such a room is a nuisance and the drops of water collecting on the roof soon cause decay and deterioration. Furthermore, in a number of chemical industries the materials used are highly hygroscopic. This is true in the manufacture of gelatine products and explosives where it is imperative that constant comparatively low temperatures and constant low moisture content be maintained. In other processes, those which involve oxidation, it is necessary that constant atmospheric conditions be maintained in order that the oxidation may be regular and rapid. This occurs more particularly in processes which involve the use of varnishes and paints.

Air conditioning is also a prime factor in the regulation of conditions in laboratories or manufacturing plants where very delicate tests are made. Balances which weigh to the fifth or sixth decimal place are affected by variations in atmospheric conditions. It is evident, by eliminating these variations, that tests, no matter how far apart, can be accurately compared.

In Candy Factories

In candy and chocolate factories, cool, dry air is an absolute requirement. If hard candy is kept in moist air for even a short period before being wrapped or hermetically sealed, the product loses its transparent color and resolves again into the appearance of granulated sugar; also the moisture makes the candy sticky and any particles broken off in the process of manufacture become affected in the same way. Automatic machinery is gummed up and eventually the whole factory must be closed down due to the fact that the machines cannot be run. If, however, moisture is taken out of the air and it is kept at a comparatively low temperature, the candy remains indefinitely as it was originally made and the particles are as so much dust which may be collected by a vacuum cleaner, as it will be a dry sand-like powder. Chocolate candy which is made in warm moist rooms assumes the familiar gray color due to the working of the cocoa oils. In this industry, too, uniform low temperatures and low moisture content are prime necessities.

In the Baking Industry

It is found that in the baking industry, a high humidity at a proper temperature maintained throughout the year will insure the baker standardized time for the rising of the dough. This is most essential where all baking and handling is done by machinery and thousands of customers wait each day for their fresh bread. The relief of a baker whose dough is ready for baking every day at the same hour can readily be imagined. The profit that results from having the bread ready at a specified time each day as compared to losses resulting from irregularity in deliveries makes an air-conditioning installation a paying investment.

In Photography

Manufacturers and users of photographic films are being greatly helped by the proper conditioning of air. Films are made by a gelatine process and are therefore not only hygroscopic, but are soft and melt in warm humid air and must be dried at a low temperature and low humidity. Without manufactured air conditions the film manufacturer must depend upon favorable natural weather to produce films. Frequent forced shutdowns result because the weather is too hot or too damp. With artificially controlled atmospheric conditions, manufacturers of moving picture films, photographic paper and dry plates can operate 365 days in the year.

Lithographing and Color Printing

Successful lithographing and color printing where more than one color is used is dependent on air conditions. One of the most important points in work of this kind is the registering of the various colors so that they blend with one another. Every one has seen pictures where this registering was not perfect. This results almost entirely from the expansion and contraction of the paper due to variations in moisture content in the printing room.

In Other Lines of Industry

In the textile, paper, chemical and drug, and meat industries, the maintenance of constant moisture content is a great factor of profit or loss. In these industries the manufacturers must protect their materials against loss of weight by loss of moisture. If textile fabrics, for instance, are allowed to become dry and are sold in the dry state, the manufacturer will lose a startling amount of money in a year. With cotton and wool at present prices one cannot buy the raw material with 12 per cent moisture in the case of wool and sell finished cloth with 4 or 5 per cent without taking a loss that would more than pay for an air-conditioning installation.

Furthermore, in the textile industry, silk, cotton and wool, static electricity is a source of constant worry to the factory superintendent, especially in winter. As the fibers pass over the machines, friction develops which causes the fibers to repel each other so that a close-spun thread or yarn with the fibers lying parallel does not result, producing, thereby, a product of inferior strength and resulting at the same time in the formation of a great deal of "fluff" or "fly." This "fly" floats around the room and is breathed by the operators. The way to overcome this condition is to add

enough moisture to the air to make it a favorable conductor of electricity so that as soon as a static change is formed in the product, it is drawn off and dissipated. Further, if enough moisture is present, the particles of "fluff" absorb moisture, become heavy and settle to the floor, where they may be readily swept up.

Equipment for air-conditioning is manufactured by the B. F. Sturtevant Co., Boston, Mass. Supplementing the manufacture of this apparatus the engineering organization of W. L. Fleisher, Inc., of New York City investigates industrial atmospheric problems.

Rennerfelt Electric Reverberatory Furnace

By H. A. De Fries

THE Rennerfelt Electric Reverberatory is based on U. S. patent 1,313,834, of Aug. 19, 1919, covering generation of electric heat by means of arcs drawn between vertical electrodes and a conducting bed located horizontally within the furnace. The rays of the heat thus generated strike the melting chambers not only directly, but also indirectly, by reverberating downward from the roof, if it is given the proper curvature.

A wide range of temperatures can be obtained by shortening or lengthening the arcs formed between the electrodes and the conducting bed, and it is also possible to obtain a smothered arc by bringing the electrodes in direct contact with this conductor. In the latter case the same conditions will prevail as in ordinary fuel-fired reverberatories. These arrangements tend to give the furnace a wide range of applications to various processes, such as the smelting of ores, reduction of chemicals, distillation processes, bullion smelting and melting, refining of copper, etc., and also melting of all of the non-ferrous metals and alloys. The construction of this furnace is made as simple and cheap as possible.

From the illustration it will be seen that the furnace is of rectangular shape, built of common firebrick, retained within a reinforced steel box for the smaller sizes and held together with buckstays, skew-backs, etc., for large capacities. The smaller sizes can be made tiltable, whereas the large furnaces will always be stationary. The roof is also of common firebrick and can be built stationary or removable as occasion may require. The electrodes enter through this roof vertically and the number of electrodes depends principally on the characteristics of the current, but to some extent also on the size of the furnace.

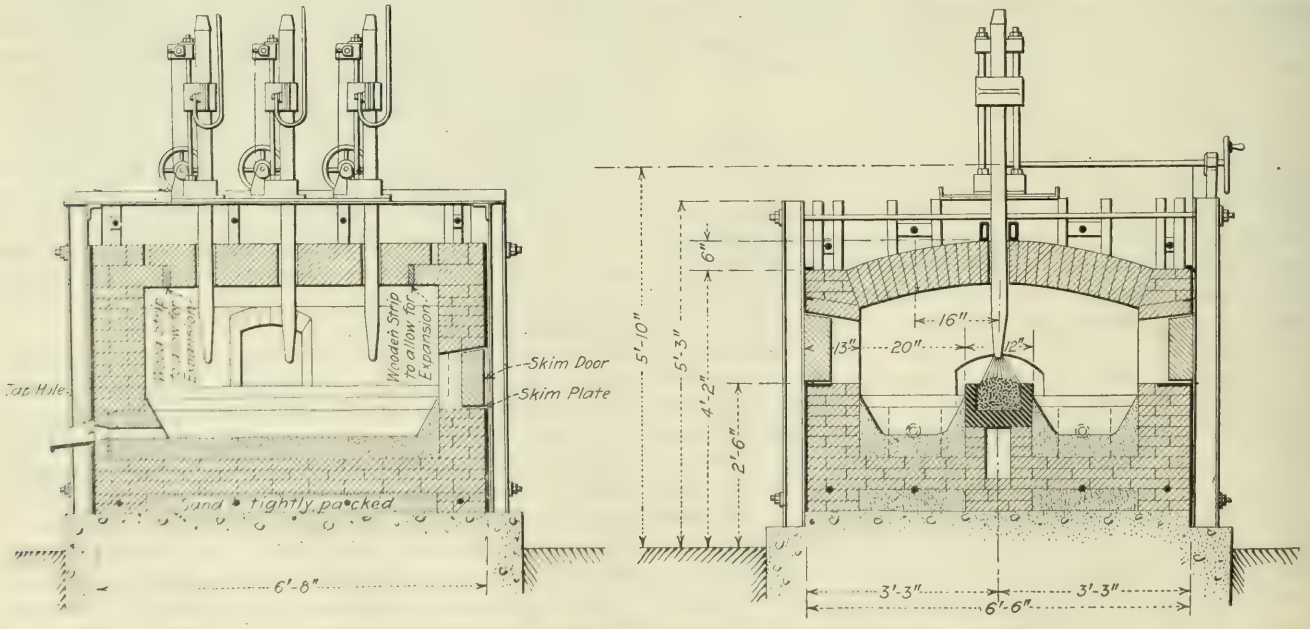
When three-phase current is available, the number of electrodes should be three or a multiple of three. In case of two-phase current, the number is two or a multiple of two. If only single-phase or direct current is available, the power is divided between two or more electrodes.

The bottom of the furnace contains the conducting bed. This bed consists of a carborundum trough in 2-ft. sections placed on a brick pier running lengthwise through the center of the furnace. The trough is filled with coarse graphite particles. This filling not only protects the carborundum trough, but also promotes smooth burning of the arcs by introducing a considerable resistance in series with the arcs and also acts as the heating element when the smothered arc is used. Doors are provided on either end of the furnace through which this trough may be removed and renewed. The filling of the trough can be renewed through these doors and also through the other working doors of the furnace.

An air duct runs the entire length of the furnace, directly beneath the carborundum trough, providing for the necessary radiation and thus insuring a longer life. The melting chambers are located on both sides and somewhat below the top of the conducting bed. These chambers are lined with either acid or basic materials, as need may require, and the bottoms slope slightly toward the tap holes, located in the front of the furnace.

It will be noted that these melting hearths are independent of each other, in other words, it is possible to charge and tap either one without disturbing the process going on in the other. This arrangement tends to cheapen the labor cost and also to increase the daily output of the furnace.

All doors are of the plug type and as many can be provided as the process would require. This type of door will permit making the furnace as airtight as possible. Ordinarily one door on either side of the furnace should be sufficient unless the furnace is of large size,



RENNERFELT ELECTRIC REVERBERATORY FURNACE

when more doors can easily be built in. In case reduction work is carried out skim plates and skimming doors should be provided for each hearth in the back of the furnace as in ordinary reverberatory furnace construction.

The electric equipment necessary for the furnace is most simple, mainly for the reason that only one voltage of 100-volt low tension will be required, as all heat regulation is obtained by fixing the distance between the conducting bed and the electrodes. No external resistance is necessary. In general, therefore, the electric equipment will consist of oil switch, transformer, instruments and the necessary cables or busbars to bring the current to the electrode contacts. The electrode regulation can be either by hand or automatic.

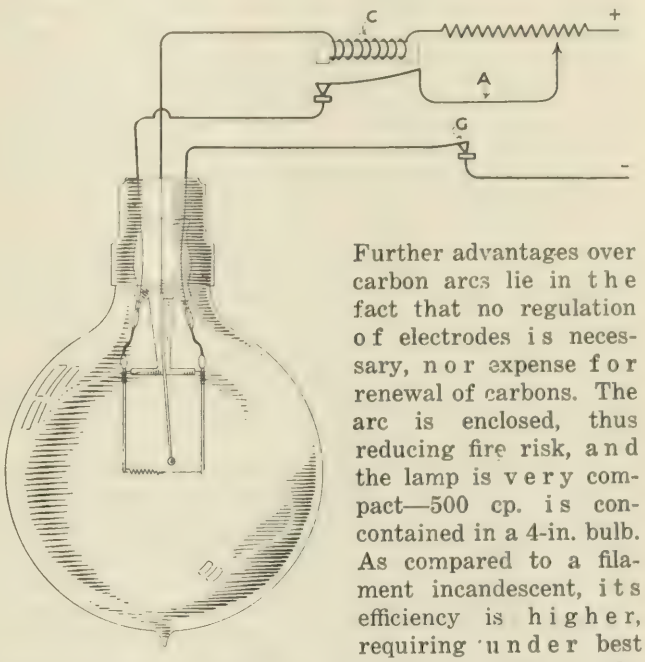
From this description it can readily be seen that the furnace is adaptable to numerous processes, and also that capacity is unlimited. As all the electrodes are in one row, any multiple can be added, thus giving additional strength to the furnace, and the width of the hearth can also be increased in proportion. When a multiple of electrodes are employed they can be connected up to the same transformer by splitting the phases, but it may be of advantage to employ a number of transformers, each controlling one set of electrodes, independent of the other. By this arrangement it is possible to regulate the heat in the various sections of the furnace.

The builder of this furnace, Hamilton & Hansell, Inc., of New York City, has also succeeded in adapting the Rennerfelt Electric Reverberatory to melting glass and enamel by making a slight change in construction and substituting tanks for the melting chamber.

Synopsis of Recent Chemical and Metallurgical Literature

A New Microscope Illuminator.—For the last three years there has been marketed in England under the name "Pointolite" a very interesting lamp, really consisting of a tungsten arc in a gas-filled globe of size of common incandescent bulbs. It was developed by E. A. GIMINGHAM and S. R. MULLARD at the laboratories of the Edison Swan Electric Co., Ltd., Ponders End, Middlesex, and described by them in the *Transactions* of the Institution of Electrical Engineers, vol. 54 (1916), p. 15. With the idea of developing a small, enclosed arc lamp with metallic electrodes, the investigators first built a globule of fused tungsten in actual contact with a brush of tungsten wires, mounting the whole in a nitrogen-filled globe of suitable size. When current was impressed, the heat so warped the supporting wires as to draw the electrodes apart, striking the arc. However, it was found that the metal soon sputtered and stuck together, so that the deformation of the metal supports could not separate the electrodes.

The successful d.c. form is illustrated herewith. To operate, switch *G* is closed, and shunt *A* leading to the filament carries practically all the current. The filament becomes incandescent, ionizing and rendering conductive the gas immediately surrounding it. At first a small current flows through the arc circuit, rapidly increasing until the cut-out is opened, breaking the ionizer circuit and striking the arc. The support is then warped by heat so that the arc moves slightly along the filament, so that the destructive action of the arc on the ionizing properties of the wire will not prevent re-starting the lamp in its cold position. Practically all the light comes from the 0.1-in. globe of fused tungsten, and does not flicker or wander in the slightest degree.



Further advantages over carbon arcs lie in the fact that no regulation of electrodes is necessary, nor expense for renewal of carbons. The arc is enclosed, thus reducing fire risk, and the lamp is very compact—500 cp. is concontained in a 4-in. bulb. As compared to a filament incandescent, its efficiency is higher, requiring under best loading only 0.3 watts per cp., its life is 500 hr., the tungsten ball has 10 times the intrinsic brilliancy of a filament—ranging up to 30,000 cp. per sq.in. The color ranges from yellow to white, depending upon the impressed current, and at heavy duty the spectrum is very continuous and strong, extending about as far into the ultra-violet as the visible range. Under these circumstances, it is readily apparent that the lamp will attract much attention from microscopists needing a continuous concentrated light from a point source.

Effect of Copper in Steel.—The Metallurgical and Testing Division, Navy Department, has made experiments on steel in which the copper content was increased to as much as 2 per cent. The gun factory has been manufacturing nickel steel with copper content between 0.4 and 0.7 per cent, and when properly handled these steels showed a marked superiority for most purposes over steel free from copper. Steel containing appreciable amounts of copper when properly made has not been found by them to be more red-short than steel of similar quality free from copper. With poorly made steel red-shortness may be found.

In successfully manufactured steel containing an appreciable amount of copper, precaution must be taken to prevent the copper from liquating or separating during solidification, as the solubility of copper is not as great in ternary alloys as is that of other alloying elements. Usual practice in the gun factory is to keep the manganese content slightly higher when the alloy carries an appreciable amount of copper, which tends to hold the copper without segregation, and prevents the tendency to red-shortness due to the presence of slightly excessive amounts of sulphur.

Steel with 2 per cent copper shows most excellent physical properties when liquation was prevented by rapid solidification of the ingot through a low pouring temperature and by use of a very heavy chill.

Recent Chemical and Metallurgical Patents

Treating Manganese Silver Ores.—LESLIE W. AUSTIN of San José, Cal., finds that it is possible to recover profitably the silver and gold from manganese silver ores by leaching with alkaline sodium cyanide solution if the ore is first treated with sulphuric acid and iron sulphide in the form of pyrite or marcasite. The treatment of the ore with sulphuric acid and pyrite reduces the manganese dioxide as indicated in the equation,

$$2FeS_2 + 15MnO_2 + H_2O = Fe_2(SO_4)_3 + 15MnO + H_2SO_4$$

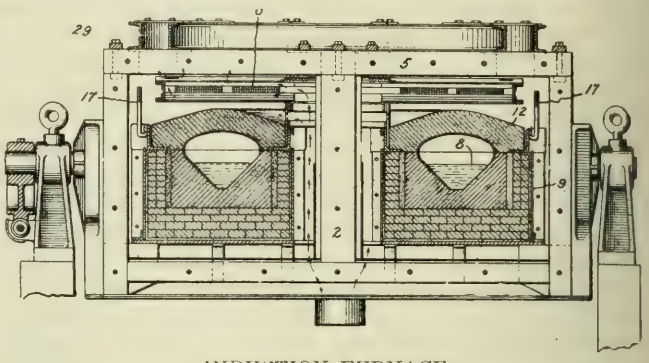
In certain cases the ferric sulphate is hydrolyzed, thus,

$$Fe_2(SO_4)_3 + 3H_2O = Fe_2O_3 + 3H_2SO_4$$

Also there may be formed manganous sulphate. The consumption of sulphuric acid is in most cases small. (1,327,974; Jan. 13, 1920.)

Precipitation of Metals From Solutions.—ARTHUR GORDON of Johannesburg, Transvaal, uses amalgamated aluminum plates for the precipitation of gold or silver from cyanide solutions. The action is more energetic than that of zinc or of a zinc-lead couple, fewer precipitation boxes are needed and it is possible to employ weaker working solutions. A considerable saving is effected thereby. The use of plates $\frac{1}{16}$ in. thick is recommended. These are amalgamated by immersion in a 1 per cent solution of mercuric chloride. The metals are precipitated by the nascent hydrogen which is liberated by the amalgamated plate from the water in the mill solution, and the mercury prevents the formation of a film of oxide on the surface of the plates. In using this method the protective alkalinity of the mill solution is increased to about 0.04 per cent, and lime is preferably used. The lime combines with the liberated hydrocyanic acid and the calcium cyanide so formed is a solvent for gold and silver. (1,328,588; Dec. 2, 1919.)

Induction Furnace.—The design of an induction furnace with the primary winding located entirely above the container for the charge or secondary winding has been suggested. The construction of a commercial furnace of this type has not been attempted, however, because it has been considered necessary to locate the legs of the core outside the essential parts of the magnetic leakage field of the primary winding and the charge. Such a design would necessitate a large core, increasing construction cost, the core loss and the amount of exciting current required. MANGUS UNGER has found that it makes no appreciable difference in the power factor of a furnace to place the legs of the core close to the primary winding and the charge container, and that this construction does not appreciably increase the stray flux loss. The magnetic core of the furnace is so proportioned that the magnetic flux density is substantially uniform when the furnace is under load. This results in a reduction of core loss and the amount of exciting current required in the primary winding. This latter is an important factor in the economy of operation. The details of the design of this furnace are shown in the illustration. The charge to be treated is contained in the annular crucible 8 located beneath the primary winding 6 and surrounding the central leg 2 of the core. The crucible has a shell 9 provided with insulated joints, is lined with firebrick and is preferably made from magnesite. The crucible cover 12 is supported from the yoke 5 by means of bolts 17, and the yoke, primary windings and crucible cover can be removed as a unit by removing bolts 29. Provision is made to cool the central leg of the core and the primary windings by forced ventilation, as shown by the arrows. The walls of the



INDUCTION FURNACE

crucible are inclined outwardly at an angle of 90 degrees to each other. This construction gives a shallow furnace chamber and permits the bringing of the charge closer to the primary winding than is possible with a deep and narrow chamber. The heating action of the induced current in the charge is greater at the surface, and with this construction the chemical action of the slag is distributed over the maximum amount of highly heated metal. (1,326,120; assigned to the General Electric Co.; Dec. 23, 1919.)

Book Reviews

LECTURE DEMONSTRATIONS IN PHYSICAL CHEMISTRY. By *Henry S. Van Klooster, Ph.D.*, of the department of chemistry, Rensselaer Polytechnic Institute. 196 pp. 83 figs. Easton, Pa.: The Chemical Publishing Co.

One opens a book of the above title with considerable curiosity, for it would seem that the field of physicochemical measurements is a most unpromising one in which to find lecture experiments. A glance at the topics listed under the twelve chapters, however, and a reading of the author's preface, give a new idea of the scope of the book, the purpose of which is to illustrate by qualitative experiments, rather than quantitative measurements, the topics usually considered in physical chemistry. The author evidently considers it a mistake to mingle physicochemical topics with descriptive chemistry, as is done in most text books of general inorganic chemistry.

In all, 253 experiments are listed, under twelve chapters bearing the following titles: General properties of matter in the liquid and solid state; diffusion; osmosis; vapor pressure and determination of molecular weights; chemical equilibrium and the law of mass action; catalysis; electrochemistry and ionic theory; solubility and its changes; colloids and adsorption; actinochemistry; flame, combustion and explosion; liquid air experiments. A bibliography, author index and subject index are included.

The author has brought together a remarkable collection of experiments, gathered from many sources. Numerous references to the original publications enhance the value of the book. It is not quite clear to what extent the author has critically studied the experiments described, and one wishes that the author had injected more of his own experience into the record. As lecture demonstrations a number of the experiments described are on altogether too small a

scale, a fault from which the art of lecture demonstration very frequently suffers. In general, however, the selection of experiments is a happy one, and it must be said that the author has made a valuable contribution in a field to which more attention might well be devoted. No teacher of physical chemistry or of inorganic chemistry can afford to be without this book. HARRY A. CURTIS.

JAMES CUTBUSH, AN AMERICAN CHEMIST, 1788-1823. By *Edgar F. Smith.* 94 pp. Philadelphia, Pa.: J. B. Lippincott Co.

This is another of Provost Smith's delightful biographies of American chemists whose names he rescues from oblivion. It is a little volume that is easily read at a sitting. If anyone should be disposed to complain of what seems almost like unanimity among Dr. Smith's heroes in regard to being born in Philadelphia, he should put an end to his repining, look up the records of his own town, and set forth his findings with similar literary charm—if he has the gift. We are eager to encourage work of this kind, and we shall not press our reservations as to Philadelphia's intellectual leadership in the nation at the time. We admit a strong prepossesion in favor of Dr. Smith and his illuminating contributions, but we deny the senatorial incapacity to see merit if it has its origin in other sources.

James Cutbush was the fourth child of a stone-cutter, Edward by given name, and his wife, Anne Marriat. This may indicate a relationship to Captain Marryat, who filled our boyhood hearts with the wish to go to sea and fight battles and see the strange world. He had two brothers, of whom one became prominent as a surgeon in the U. S. Navy, while the other graduated from West Point and attained eminence as an engineer. Where James studied and how is not recorded, but he appears in 1808—at the age of twenty, as the author of some fifteen articles in a Philadelphia newspaper called *Aurora,* in which he explains according to the light of his day many processes of a chemical nature, and urged, as he did throughout his life, the application of the science to industry.

After the death of James Woodhouse, in 1811, when the old Chemical Society of Philadelphia went out of existence, "a number of persons desirous of cultivating chemical science" founded a successor organization, and named it the Columbian Chemical Society. Each year at the fall opening "an oration on some chemical subject" was delivered, and every month "original chemical essays" were presented. We call them all "papers" nowadays, and it might improve the form of some of them if we were to place the responsibility upon the writers of a higher finish, a greater literary polish, in connection with their work. The "Hon. Thomas Jefferson, Esq., was the Patron," and its president was "James Cutbush, Esq., professor of natural philosophy, chemistry and mineralogy in St. John's College." At this time he was twenty-three years old. St. John's College was established and maintained by a Lutheran church of that name in Philadelphia.

Dr. Smith gets a line on Cutbush from a newspaper advertisement of October, 1819, which reads:

Bleaching Liquor, Artificial Musk, Phosphate of Mercury, and Other Chemical Preparations
prepared and sold by
James Cutbush
Chemist and Apothecary
No. 25 South Fourth Street, Philadelphia,
where complete collections of chemical reagents are kept as usual.

Throughout several years announcements are found by Cutbush in St. John's Lyceum and elsewhere on general chemistry, the theory and practice of pharmacy and other subjects. On Nov. 7, 1811, he delivered an oration before the Society for the Promotion of a Rational System of Education. Dr. Smith says: "His audience was large, and consisted of the very best people of the city. The printed address shows that in addition to his chemical knowledge he was versed in the humanities, in mathematics, in philosophy and ancient history." He urged the introduction of physical science into the curriculum of schools. It hardly seems out of date now, a century later.

Another note that has a modern turn to it is that "He is often referred to as Dr. Cutbush, and in at least two instances the title M.D. is placed after his name. Yet it is a fact that in no place where he is personally responsible for the printing of his name is there any title affixed to it." Apropos of doctorates of courtesy and convention as distinguished from those of academic origin, our readers may recall that in our lament for the passing of William, the dusky servitor of the Chemists' Club, it was observed that as soon as William learned the name of a newly elected member, he addressed him from that time forth as Doctor. These titles were pleasant to the unaccustomed ear, and became known in time as "William's College Degrees." Some of them have remarkable adhesive qualities.

In 1814 James Cutbush was appointed assistant apothecary general to the U. S. Army, although in 1819 he was still in Philadelphia prosecuting his duties. In 1820 he was appointed chief medical officer in the U. S. Military Academy at West Point, where later he became professor of chemistry. Here he addressed himself vigorously to problems of pyrotechnics and explosives. Several pages of questions in regard to pyrotechny are given to indicate his scholarship and methods. His posthumous work on the subject, printed in 1825, has for many years been consulted and referred to by men of science. He was the great pioneer in this field. He must have been a man of mark and attractive personality. Over his grave at West Point is carved this inscription: "Sacred to the Memory of Dr. James Cutbush, Member of the American Philosophical Society, Late Surgeon U. S. Army and Professor of Chemistry, West Point, N. Y., who departed this life Dec. 15, 1823, aged thirty-five years. An honorable tribute of respect from his grateful pupils."

ELLWOOD HENDRICK.

A HANDBOOK OF BRIQUETTING. VOL. II. By *G. Franke.* 214 pp., illustrated. Philadelphia, Pa.: J. B. Lippincott Co.

While this book is the second volume of a series published by the author, it is a complete work in itself on the briquetting of ores and metallurgical products. The author is evidently eminently qualified to prepare such a text on this subject, as demonstrated in both this and previous volumes. A reference to and description of plants employing the processes deal mainly with European practice, for the application of briquetting processes to various metallurgical products has progressed far beyond that in American plants.

In addition to briquetting proper, agglomeration or sintering of ores and metallurgical products is also dealt with. This process consists of converting suitable fine material into lumps adapted to the particular smelting operation, without calling in the aid of the processes of molding and compression.

The book opens with a section on the various metallic briquetting materials, with reasons for, and objects of, briquetting them. Briquet testing and characteristics of good briquets, and the composition of various metallurgical and smelting briquets and agglomerates are dealt with. The subject of methods involved in briquetting is thoroughly covered, commencing with the hand-molding of the simple briquet and finishing with fusion processes in electric furnaces, these methods involving the briquetting of materials both with and without binders.

Preparation of the material and subsequent treatment for smelting and fusion embraces a series of chapters which should be of interest to all engineers and operators concerned with metallurgical plants, not only those who are interested in the design of complete new plants, but also where certain additions are contemplated in the existing processes as will effect a saving in the smelting of products which are now considered wastes. The author further enters into descriptions of complete briquetting plants now in operation in European countries. These installations are liberally illustrated by photographs and drawings.

The final pages of the work embrace appendices to both Vols. I and II, which contain further results of tests on pitch and coal briquets, cost of heat, and Hemmerling's

methods for the production of compressed peat blocks; treatment of coal slimes, and briquetting of flue dust.

A careful examination of the text matter shows a large amount of detail on briquetting methods which should be of considerable value to those interested in operating or installing briquetting plants, and the work should command the interest and attention of many who do not now consider themselves concerned with briquetting. American manufacturers are now producing machinery which adequately serves the function of producing briquets under the methods described in this book. CHESTER H. JONES.

Personal

HARRY E. BISHOP has resigned from the staff of the State Board of Health Laboratories, Indianapolis, Ind., to accept a position in the research laboratory of the National Association of Manufacturers of Glass Containers, Chicago, Ill.

J. S. BROGDON and W. C. DUMAS, formerly state chemist of Georgia, have organized the Brogdon-Dumas Laboratories, Inc., for the conduct of general business as assayers and chemists at Atlanta, Ga.

HERBERT R. HANLEY has returned to San Francisco from a trip to the various Arizona smelters.

Dr. ARTHUR R. HITCH has resigned his position as chief chemist for the Ashland Iron & Mining Co., Ashland, Ky., to accept a position as research chemist with E. I. du Pont de Nemours & Co., at its Jackson Laboratories, Wilmington, Del.

G. W. LAMBOURNE, general manager of the Judge Mining & Smelting Co., has returned to Salt Lake City from a business trip to the Coast.

WILLIAM L. LONG, formerly with Swan-Myers, Indianapolis, Ind., is now chemist with the H. K. Mulford Co., Philadelphia, Pa.

GEORGE D. MCLAUGHLIN has resigned his position as chief chemist of Kullman, Salz & Co., to do research work in colloid chemistry under Dr. Martin H. Fischer, at the University of Cincinnati, Cincinnati, Ohio.

JOHN G. MCLEOD, JR., is now research chemist in the technical service department of the Brompton Pulp & Paper Co., Ltd., East Angus, Que., Canada.

Dr. CHARLES S. PALMER, formerly of the Mellon Institute, Pittsburgh, Pa., has joined the United Fuel Gas Co., Charleston, W. Va., as chief chemist.

B. B. THAYER, vice-president of the Anaconda Copper Mining Co., sailed for Chile on Jan. 31, to inspect the company's properties.

Dr. MAXIMILIAN TOCH of Toch Bros., New York, has been appointed professor of industrial chemistry at Cooper Institute, New York, to lecture on paints, drying oils, resins and rubber.

J. E. TOOMER, formerly research chemist with the Chino Copper Co., Hurley, N. M., has accepted the position of chief chemist with the Morris Fertilizer Co., Atlanta, Ga.

Obituary

PAOLO FISCHER, at one time an assistant to Stassano, the Italian builder of electric furnaces, died recently in Chicago. Mr. Fischer was widely known in Europe in connection with the early development of the electric furnace. He designed the plant which was operated for some time at Buchanan, Mich., and more recently had designed a proposed plant for installation near the Keokuk dam.

C. H. INGRAM, of the Ruhm Phosphate Mining Co., died Jan. 8 at Mt. Pleasant, Tenn., after a short illness from pneumonia. Mr. Ingram had been actively connected with the phosphate business since its discovery in Tennessee and was widely known and very popular in the trade.

Current Market Reports

The Non-Ferrous Metal Market

New York, Feb. 9, 1920.—Little movement in the market. Nickel remained stationary; copper, zinc, tin and silver declined slightly; lead advanced from 8.62½c. to 8.80c., New York.

	Cents per Lb.
Copper, electrolytic	18.50
Aluminum, 98 to 99 per cent	31½@32½
Antimony, wholesale lots	11.50
Nickel, ordinary	43.00
Nickel, electrolytic	45.00
Tin, Straits, spot	57.50
Lead, New York, spot	8.80
Lead, E. St. Louis, spot	8.45
Zinc, spot, New York	9.05
Zinc, spot, E. St. Louis	8.70
Silver (Dollars per oz.)	1.32¾

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb
Copper sheets, hot rolled	29.50
Copper sheets, cold rolled (over 14 oz.)	31.50
Copper bottoms	38.00
Copper rods	27.50
High brass wire and sheets	25.25
High brass rods	23.75
Low brass wire and sheets	27.25
Low brass rods	28.00

Lead, heavy	6⅜@7
Zinc, scrap	4¼@4½

The Iron and Steel Market

Pittsburgh, February 6, 1920.

The runaway steel market, referred to in last report as having in all probability developed, is clearly defined as such. The market is nothing if not a runaway. There are no regular market prices. The Steel Corporation subsidiaries have a very well defined schedule of prices, the March 21, 1919, or "Industrial Board" schedule, but only its regular customers can buy at those prices, and then in many cases not as large tonnages as they desire. Among the independents there is probably not one that is willing to sell anyone at the March 21 schedule, while furthermore the prices quoted by independents, when they quote at all, very seldom agree. Competition does not force the market of the independents to a definite level, for the reason that the individual producers do not offer as much steel as buyers desire to purchase.

While technically there is a clearly defined condition of a runaway market, it cannot be observed that the market is running away very fast. Whether this feature is due to reserve on the part of sellers or reserve on the part of buyers cannot be determined at this time. No canvass of buyers can be made which would show the distance ahead to which they are willing to commit themselves at one price or another if given the opportunity.

One large independent steel interest is engaged in its own effort to stabilize the market, but apparently has no company. Its prices for a variety of steel products, with perhaps an occasional exception, are what are known as "Jan. 1" prices, the prices from which the Industrial Board reductions were made March 21, and to which prices were

reduced shortly after the armistice. The Jan. 1 prices are, for illustration, 2.70c., 2.80c. and 3c. for bars, shapes and plates respectively.

Operations

Steel production in January was not far from 85 per cent of capacity, and while the tonnage proved larger than had been predicted, the producers profess themselves much disappointed at conditions today, there having been little if any further increase in the production rate since the middle of January. With scarcely an exception producers ascribe the restriction to a shortage in transportation, which touches the industry in various ways—in preventing an increase in production and shipment of Connellsville coke, in limiting the shipment of coal for steel mill and byproduct oven use and in preventing all steel made from being shipped. At some mills there are large accumulations of finished product threatening to back up against the rolls and force stoppages. The railroads are not disorganized, but they have not the reserve force to cope with existing conditions, particularly the winter weather. Given a continued summer they might do fairly well.

The automobile industry is having an influence upon the steel market that is greatly regretted by many other classes of consumers, as the automobile factories are so situated that it is a matter of indifference to them what prices they pay for such small lots of steel, relative to their regular supplies, as they need in order to maintain operations. Some steel buyers feel strongly that the automobile industry is making an impress upon the steel market out of proportion to the tonnage importance of the additional steel it now requires, for all or nearly all the established factories have large tonnages of steel reaching them from week to week on old contracts, at prices much below those now bid for small prompt lots.

Lake Superior Iron Ore Market Opens

The Lake Superior iron ore market for the 1920 season was opened in Cleveland Monday, Feb. 2, by representative sales, and in accordance with a habit formed long ago the producers will adhere during the season to the prices thus developed. There is a uniform advance on the four groups of ores of $1 per ton over the 1919 schedule, making prices as follows at Lake Erie docks: old range bessemer, $7.45; old range non-bessemer, $6.70; Mesabi bessemer, $7.20; Mesabi non-bessemer, $6.55. These prices are the highest in a statistical record which begins with 1894 in the case of Mesabi ores and with 1885 in the case of old range ores. The advance, however, is moderate relative to the prevailing prices of pig iron. Mesabi non-bessemer, for instance, is at the new rate 95 per cent above its 10-yr. pre-war average in the seasons of 1904 to 1913 inclusive, while pig iron is fully 150 per cent above its corresponding pre-war average.

Pig Iron

The pig iron market is in stronger position, although no additional advances are to be recorded for the past week. Foundry iron is $40, Birmingham, and foundry and basic $40, valley, with bessemer at $41. These quotations are based on last important sales, but it is doubtful whether much additional tonnage can be had at the prices, while buyers are taking hold somewhat more freely than formerly.

Unfinished Steel

No definite prices can be quoted for unfinished steel, each of the few transactions made being a law to itself. In the past week a sale of sheet bars has been made at $65 and another at $56, the circumstances not being greatly different as to tonnage and delivery. Small billets have sold at $60.

The Ferro-Alloy Market

New York, February 7, 1920.

The car shortage is hitting the manufacturers not only in the scarcity of incoming raw material but also in the outgoing product. Deliveries on contracts are being delayed and producers are taxing their resources to keep the mills supplied.

Ferromanganese continues the most important item of the alloys; difficulty is experienced in obtaining it at $160 per ton. Spiegeleisen is strong under the impetus of the manganese demand, and the average price quoted is around $55 per ton. There has been some small business in ferrochrome at 25c. per lb., but buyers are few and far between.

The coke situation remains unchanged, indifference on the part of labor to the necessity of increasing production, extreme car shortage (totaling 30 to 35 per cent of normal number of cars), and the cold weather have successfully combined to practically cripple this industry.

The Chemical Market

New York, February 7, 1920.

The chemical market during the past week continued evenly balanced, with a slight drop in activity probably due to a scarcity of spot material. Prices have not been affected by this scarcity and remain at practically the same level as the previous report.

Aqua ammonia remains firm at 8¾@10¾c. due principally to the lack of supplies caused by the recent coal shortage. This item has not recovered, and with the present demand prices will continue at the present level. Manufacturers are offering *white sal ammoniac*, granular, at 12¾@14c. per lb. and the gray at 12@12½c. Spot materials are scarce, but contracts for forward delivery are being taken. *Bleaching powder* is practically off the spot market at present. Manufacturers who are fairly well sold up on this item are quoting $2.50@$3 per cwt. *Glauber's salts* has been quiet. Buyers have been taking a routine supply, but with the present stocks no immediate rise is looked for.

Potassium carbonate is difficult to locate on spot, but there has been some trading at 24@27c. per lb., mostly on contract, as the entire supply is in the hands of a few. *Potassium hydroxide* remains firm at 23@32c. per lb. There has been some business in spot goods in a small way at 30c. per lb. *Oxalic* has had another jump and is now quoted at 35@40c. per lb. Import grades from England are to be had at 38c. but domestic producers with their rather scanty stock are holding firm at 40c.

Coal-Tar Products

This branch of the market has been quiet during the past week, due principally to uncertainty as to the tariff, which is at present under discussion in Washington. Opinion is divided regarding what action Congress should take, the producer of coal-tar intermediates and dyestuffs holding that a restrictive tariff should be placed on all imported goods sufficient to protect the domestic manufacturer, while the textile and mill people, who desire to obtain these items at the lowest possible figure, claim this would do away with competition. Definite action will certainly ease the market. *Cresylic acid*, 97-99 per cent, has advanced from 75@80c. per gal. of last week to 90c.@$1.10, while 95-97 per cent also came up to 80c@$1, with supply falling off, and further advances are looked for soon. *Phthalic anhydride* remains at 60c. per lb. There are plentiful stocks of this material in the hands of large producers. Through a typographical error the prices on *salicylic acid* were reversed. The present quotation is 43@45c. per lb. for tech. and 55@60c. for U. S. P. grade. *Benzol* has been easier due to a replenished stock. This item can be obtained by actual users in reasonable quantities for prompt shipment at 27c. per gal. *Phenol* remains unchanged and the large stocks on this item have kept the price at 12c. per lb.

Naval Stores

Turpentine continues upward, the present quotation in the local market being $2.04 per gal., while Savannah is quoted at $1.97 per gal. *Rosins* remain firm with a slight falling off in inquiry.

Crude Rubber

The crude rubber market continues easy, buyers holding out for more favorable prices. Manufacturers are fairly well supplied and are not in the market except for concessions, and the present indication is that a still further drop will take place.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	.....	$0.60 – $0.65
Acetone	lb.	$0.16 –$0.20	.21 – .....

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.60
Alpha naphthylamine	lb.	.34 —	.36
Aniline oil, drums extra	lb.	.34 —	.36
Aniline salts	lb.	.42 —	.50
Anthracine, 80% in drums (100 lb.)	lb.	.75 —	1.00
Benzaldehyde (f.f.c.)	lb.	2.00 —	2.10
Benzidine, base	lb.	1.25 —	1.30
Benzidine, sulphate	lb.	.90 —	1.00
Benzoic acid, U.S.P.	lb.	.90 —	1.10
Benzoate of soda, U.S.P.	lb.	.80 —	1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.27 —	.36
Benzol, 90%, in drums (100 lb.)	gal.	.25 —	.29
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	.50 —	.52
Beta naphthol, sublimed	lb.	.65 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U.S.P., in drums (100 lb.)	lb.	.16 —	.18
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.90 —	1.10
Cresylic acid, 95-97%, dark, in drums	gal.	.80 —	1.00
Cresylic acid, 50%, first quality, drums	gal.	.70 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.40 —	1.50
Dimethylaniline	lb.	.90 —	1.00
Dinitrobenzol	lb.	.26 —	.37
Dinitrochlorbenzol	lb.	.25 —	.30
Dinitronaphthaline	lb.	.45 —	.55
Dinitrophenol	lb.	.32 —	.36
Dinitrotoluol	lb.	.38 —	.45
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 —	.40
Diphenylamine	lb.	.58 —	.75
H-acid	lb.	1.60 —	1.75
Metaphenylenediamine	lb.	1.15 —	1.80
Monochlorbenzol	lb.	.12 —	.15
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline crushed, in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.08½ —	.10
Naphthionic acid, crude	lb.	.75 —	1.25
Nitrobenzol	lb.	.14 —	.19
Nitro-naphthaline	lb.	.30 —	.35
Nitro-toluol	lb.	.20 —	.30
Ortho-amidophenol	lb.	3.00 —	4.25
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	.90 —	1.25
Ortho-nitro-toluol	lb.	.25 —	.40
Ortho-toluidine	lb.	.25 —	.45
Para-amidophenol, base	lb.	2.50 —	3.50
Para-amidophenol, HCl	lb.	2.50 —	3.25
Para-dichlor-benzol	lb.	.15 —	.18
Paranitraniline	lb.	1.00 —	1.20
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	2.50 —	4.00
Paratoluidine	lb.	2.00 —	2.50
Phthalic anhydride	lb.	.60 —	1.00
Phenol, U.S.P., drums (dest.), (240 lb.)	lb.	.12½ —	.19
Pyridin	gal.	2.00 —	2.50
Resorcin, technical	lb.	3.75 —	4.50
Resorcin, pure	lb.	6.50 —	6.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.43 —	.45
Salicylic acid, U.S.P.	lb.	.55 —	.60
Salol	lb.	.90 —	.95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.22 —	.27
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.19 —	.24
Sulphanilic acid, crude	lb.	.25 —	.30

Toluidine	lb.	$1.70 —	$2.50
Toluidine, mixed	lb.	.45 —	.55
Toluol, in tank cars	gal.	.28 —	.....
Toluol, in drums	gal.	.29 —	.32
Xylidine, drums, 100 gal.	lb.	.44 —	.50
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal.	gal.	.37 —	.45
Xylol, commercial, in tank cars	gal.	.23 —	.27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.42 —	$0.45
Beeswax, refined, yellow	lb.	.47 —	.48
Beeswax, white, pure	lb.	.63 —	.68
Carnauba, No. 1	lb.	.80 —	.88
Carnauba, No. 2, regular	lb.	.65 —	.78
Carnauba, No. 3, North Country	lb.	.46 —	.48
Japan	lb.	.18½ —	.20
Paraffine waxes, crude match wax(white) 105-110 m.p.	lb.	.06 —	.07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	..... —	.07
Paraffine waxes, refined, 118-120 m.p.	lb.	..... —	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½ —	.10½
Paraffine waxes, refined, 133-135 m.p.	lb.	..... —	.13
Paraffine waxes, refined, 135-137 m.p.	lb.	..... —	.14
Stearic acid, single pressed	lb.	.23 —	.26
Stearic acid, double pressed	lb.	.28 —	.29
Stearic acid, triple pressed	lb.	.32 —	.33

NOTE—Quotations on paraffine waxes are nominal.

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940	gal.	$1.45
Pine oil, pure, dest. dist	gal.	....
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.40
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.48
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.70
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.	.38
Turpentine, crude, sp.gr., 0.900-0.970	gal.	1.60
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.	.35
Pinewood creosote, ref	gal.	.52

Naval Stores

The following prices are f.o.b., New York, for carload lots:

Rosin B-D, bbl	280 lb.	$19.00 —	$19.50
Rosin E-I	280 lb.	19.50 —	19.70
Rosin K-N	280 lb.	19.75 —	22.50
Rosin W. G.-W. W	280 lb.	22.50 —	24.25
Wood rosin, bbl	280 lb.	17.00 —	17.50
Spirits of turpentine	gal.	.... —	2.04
Wood turpentine, steam dist	gal.	.... —	1.70
Wood turpentine, dest. dist	gal.	1.64 —	....
Pine tar pitch, bbl	200 lb.	8.25 —	8.50
Tar, kiln burned, bbl. (500 lb.)	bbl.	14.50 —	14.75
Retort tar, bbl (500 lb.)	bbl.	15.00 —	15.25
Rosin oil, first run	gal.	.... —	.91
Rosin oil, second run	gal.	.93 —	.94
Rosin oil, third run	gal.	1.10 —	1.12
Rosin oil, fourth run	gal.	.... —	1.15

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naptha, steel bbls. (85 lb.)	gal.	.23½

Crude Rubber

Para—Upriver fine	lb.	$0.44 —	$0.46
Upriver coarse	lb.	.33 —	.35
Upriver caucho ball	lb.	.33½ —	.34½
Plantation—First latex crepe	lb.	.50 —	.54½
Ribbed smoked sheets	lb.	.49 —	.51
Brown crepe, thin, clean	lb.	.48	.48½
Amber crepe No. 1	lb.	.53 —	....

Oils

VEGETABLE

The following prices are f.o.b., New York, for carload lots:

Castor oil, No. 3, in bbls	lb.	$0.18 —	$0.19
Castor oil, AA, in bbls	lb.	.21 —	.23
China wood oil, in bbls	lb.	.23½ —	.24½
Cocoanut oil, Ceylon grade, in bbls	lb.	.21 —	.21½
Cocoanut oil, Cochin grade, in bbls	lb.	.20½ —	.23
Corn oil, crude, in bbls	lb.	.19 —	.22
Cottonseed oil, crude (f.o.b. mill)	lb.	.19 —	.20
Cottonseed oil, summer yellow	lb.	.22 —	.27
Cottonseed oil, winter yellow	lb.	.24½ —	.25½
Linseed oil, raw, car lots	gal.	1.77 —	1.87
Linseed oil, raw, tank cars	gal.	1.70 —	1.80
Linseed oil, boiled, car lots	gal.	1.75 —	1.80
Olive oil, commercial	gal.	2.50 —	2.60
Palm, Lagos	lb.	.17 —	.18
Palm, bright red	lb.	.16½ —	.17½
Palm, Niger	lb.	.16 —	.17½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.23½ —	.24
Peanut oil, refined, in bbls	lb.	.27 —	.28
Rapeseed oil, refined in bbls	gal.	1.45 —	1.68
Rapeseed oil, blown, in bbls	gal.	1.60 —	1.70
Soya bean oil (Manchurian), in bbls. N Y	lb.	.19 —	.23
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.17½ —	.20

Structural Steel

Mill, Pittsburgh

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.65
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.85
Sheets, No. 10 blue annealed	100 lb.	4.00
Sheets, No. 28 galvanized	100 lb.	6.20

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Connecticut

NEW HAVEN—The State Bd. of Health, 308 Church St., Hartford, and Bilderbeck & Langdin, archts., Manwaring Bldg., New London, will receive bids about March 1 for the construction of a 3-story, 51 x 111 ft. laboratory and experimental station on Highland St. Testing and experimental apparatus will be installed in same. Total estimated cost, $125,000.

Illinois

CHICAGO—The Illinois Glass Co. is having plans prepared for the construction of an addition to the plant which will be built at Crawford and Whitewood Aves. Estimated cost, $250,000. The company also plans to build addition to the plants of the United States Bottlers' Machinery Co., and the Kimble Glass Co., subsidiary corporations, at a cost of $250,000. Herbert H. Green, archt.

CHICAGO—Lindstrom, Smith & Co., 1104 South Wabash Ave., has awarded the contract for the construction of a 1-story, 130 x 250-ft. factory for the manufacture of electrical specialties, on Lake St. and Kedzie Ave., to Jacob Rodatz, 209 South LaSalle St. Estimated cost, $125,000.

Iowa

SIOUX CITY—The Sioux City Soap Co., 302 Grain Exch. Bldg., plans to build a soap factory.

Kansas

BAXTER SPRINGS—The Empire Development Co. plans to move its old Kentex Mill from Quapaw to a site which it has leased, southwest of here. The company is in the market for 1 compressor, 2 gas engines, 9 tables, rolls and screens. E. Mallocsay, supt.

TOPEKA—The city plans to construct a 10,000,000-gal. filtration plant. Estimated cost, $190,000.

Kentucky

RIVERSIDE—The Standard Oil Co., 424-30 West Bloom St., Louisville, is having plans prepared for the construction of additions to its refinery at Riverside Station. The new plant will more than double the present capacity. Estimated cost, $2,000,000.

Louisiana

MONROE—N. C. McGowan, Shreveport, plans to build a carbon black plant about 17 mi from here. Estimated cost, $250,000.

SHREVEPORT—R. S. Seamans, pres. of the Foursome Oil Co., plans to build a 5,000-bbl. refinery. Estimated cost, $600,000.

Maine

PORTLAND—The Amer. Can Co., B'way, New York City, has awarded the contract for the construction of a cannery, to the Turner Constr. Co., Tremont St., Boston, Mass. Chemical equipment, etc., will be installed in same.

PORTLAND—A. S. Hinds, 20 West St., has awarded the contract for the construction of a 90 x 150-ft. laboratory, to Lorello & Piofano, 217 Stevens Ave. Chemical equipment will be installed in same. Estimated cost, $150,000.

Maryland

BALTIMORE.—A. H. Kuhlemann Co., 2961 Frederick Ave., has awarded the contract for the construction of a 3-story, 75 x 200-ft. factory for the manufacture of oleomargerine, on Frederick Ave., to W. L. and G. H. O'Shea, 29 B'way, New York City. Estimated cost, $100,000.

Massachusetts

BOSTON—The Simbroco Co., 161 Devonshire St., has awarded the contract for the construction of a 1-story, 60 x 200-ft. factory at 270 Baker St., for the manufacture of concrete products, to Simpson Bros. Co., 166 Devonshire St. Estimated cost, $70,000.

New Jersey

NEWARK—The General Lead Batteries Co., 123 West 56th St., New York City, is having plans prepared for the construction of a 5-story factory on Lester Ave. and Chapel St. Estimated cost, $150,000. Timmis & Chapman, 315 5th Ave., New York City, archts. and engrs.

NEW BRUNSWICK—George E. Maguire, pres. Trenton Porcelain Co., 803 East State St., will soon award the contract for the construction of a 2-story, 32 x 100-ft. porcelain plant. Estimated cost, $20,000. W. A. Kleman, 1st Natl. Bank Bldg., archt.

New York

BUFFALO—The Buffalo Porcelain & Enameling Co. plans to construct a 2-story factory at 1927 Elmwood Ave. Estimated cost between $20,000 and $25,000.

ITHACA—C. D. Bostwick, comptroller, Cornell University, will receive bids until Feb. 24 for the construction, heating, sanitary and electric work at the Laboratory for Economic Investigation of Insects, New York State College of Agriculture, here.

UTICA—The Bowen Mfg. Co., manufacturer of paper and twine, 401 Columbia St., has awarded the contract for the construction of a 1-story, 102 x 225-ft. factory, to the Kimberly Constr. Co., Mayno Bldg. Estimated cost, $29,000.

Ohio

CINCINNATI—The Jarecki Chemical Co., Broerman Ave., has awarded the contract for the construction of a 1-story, 120 x 350-ft. factory, to the Austin Co., 16112 Euclid Ave., Cleveland. Estimated cost, $300,000.

CLEVELAND—The Crucible Steel Forge Co., 6600 Grant Ave., has awarded the contract for the construction of a 1-story, 60 x 900-ft. rolling mill, annealing plant and machine shop on Grant Ave., to the Masters & Mullen Constr. Co., Electric Bldg. Estimated cost, $500,000. Noted Jan. 7.

CLEVELAND—The Hydraulic Pressed Steel Co., Hydraulic Ave., has awarded the contract for remodelling the 1-story heat treating plant on Hydraulic Ave., to E. R. Russell, Sincere Bldg. Estimated cost, $10,000.

LIMA—The Union Tank Line Co. has purchased a 130-acre site adjoining the property of the Solar Refinery and plans to build a large tank factory on same. Estimated cost, $20,000,000.

Oklahoma

BEGGS—The Kre-Ko Refining Co., Bristow, is having plans prepared for the construction of a 1-story, 3,000-bbl. refinery, 1 mi. north of here. Estimated cost, $400,000. John D'Arcey, genl. mgr. Foster & Gilmore, Tulsa, archts. and engrs.

South Carolina

CHARLESTON—The Commissioners of Pub. Wks., Water Dept., 14 George St., have awarded the contract for the construction of a filter plant, consisting of fourteen 1,000,000-gal. units, to the New York Continental Jewell Filtration Co., Flatiron Bldg., New York City. Estimated cost, $125,000.

Texas

CLINTON—The Keen & Wolf Refining Co., 317 Beatty Bldg., Houston, is having plans prepared for the construction of a 1,000-bbl. oil refinery, including several buildings and 5 stills, near here. Estimated cost, $300,000. A. Peterson, care of company, chief engr.

QUANNAH—The Four States Oil & Refining Co. plans to build a 1-story refinery, south of here. Estimated cost, $400,000.

RANGER—The International Oil & Refining Co. plans to build a refinery. Estimated cost, $300,000.

RANGER—The Olda-Clark Refining Co. plans to build a refinery. Estimated cost, $250,000.

Wisconsin

CLEAR LAKE—W. L. Albans, archt., Endicott Bldg., St. Paul, Minn., will soon award the contract for the construction of a 2-story, 53 x 94-ft. high school, for the Bd. Educ. A septic tank will be installed in same. Estimated cost, $60,000.

CUDAHY—The Federal Rubber Co., Packard Ave., is having plans prepared for the construction of three 6-story, 160 x 220-ft. factory buildings. G. B. Allen, 424 Jefferson Ave., Milwaukee, archt. and engr.

MILWAUKEE—The Westinghouse Lamp Co., 32nd and Center Sts., plans to construct two 3-story, 75 x 300-ft. additions to its factory on 32nd St.

Ontario

BELLEVILLE—The Bd. Educ. plans to build a 3-story Collegiate Institute. Chemical and physical laboratory equipment will be installed in same. Estimated cost, $350,000. A. McGie, chn.

LONDON—The city plans to build a sewage disposal plant to include an Imhoff tank or activated sludge system. Estimated cost, $250,000.

TORONTO—The Bd. Educ. plans to construct 2- and 3-story additions to various schools in the city. Chemical and physical laboratory equipment will be installed in the high schools, collegiate and technical schools. Estimated cost, $1,500,000. W. W. Pearse, 155 College St., Mgr.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold its fifth annual convention at the Planters Hotel in St. Louis, May 10 and 11.

THE AMERICAN CERAMIC SOCIETY will hold its annual meeting in Philadelphia, Pa., Feb. 23 to 26. Headquarters are at the Bellevue-Stratford Hotel.

THE AMERICAN CHEMICAL SOCIETY will hold its annual meeting April 13 to 16 inclusive, in St. Louis. Headquarters will be at the Hotel Statler.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Boston, April 8, 9 and 10. Headquarters will be at the Copley-Plaza Hotel.

THE AMERICAN ELECTROCHEMICAL SOCIETY, NEW YORK SECTION, will have a meeting on Feb. 27, the subject for which is "Electric Furnace Reducing Agents." Another meeting will be held on March 26, the subject of which is "Peace Uses for War Products."

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York, Feb. 16 to 19.

THE AMERICAN PETROLEUM LEAGUE will hold a meeting in Chicago, March 26 to 29.

THE FARADAY SOCIETY (London) will hold a joint meeting, March 1, with the London Section of the Society of Chemical Industry to receive and discuss a report of Dr. T. Martin Lowry, and E. C. Hemmings on the "Setting of Salts and Other Crystalline Substances." Another meeting will be held March 23, at which there will be a general discussion on "Basic Slag From the Metallurgical and Agricultural Standpoints."

THE INSTITUTE OF METALS will hold its annual general meeting March 11 and 12 at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S. W. 1, London, England.

THE IRON AND STEEL INSTITUTE (London) will hold its annual meeting May 6 and 7, 1920, at the House of the Institute of Civil Engineers, Great George St., London, S. W. 1. The retiring president, Eugene Schneider, will induct into the chair Dr. J. E. Stead, the president-elect.

THE MATERIAL HANDLING MACHINERY MANUFACTURERS' ASSOCIATION will hold its convention at the Waldorf-Astoria Hotel, New York City, Feb. 26 and 27.

THE NATIONAL FERTILIZER ASSOCIATION will hold its twenty-seventh annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 21.

THE NATIONAL FOREIGN TRADE CONVENTION will be held in San Francisco, May 12 to 15.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its spring meeting at the Hotel Waldorf and the Hotel Astor, New York City, April 12 to 16.

Proposed Amalgamation Of Heat-Treating Societies

A WELL-DEFINED movement has been instituted looking toward the amalgamation of the American Steel Treaters' Society and the Steel Treating Research Society. It will be recollected that about two years ago the Chicago section of the Steel Treating Research Society, whose general offices were in Detroit, became dissatisfied with the conduct of the parent society and seceded, forming the American Steel Treaters' Society, with headquarters in Chicago. Some time later, under the energetic leadership of W. H. EISENMAN, business manager of the younger organization, a campaign for members was instituted which resulted in the formation of a number of new chapters, in some instances invading the territory already occupied by a local section of the Detroit body. This could not help but cause intense rivalry between the competing bodies, both local and national, and as a natural result more or less recrimination and unpleasantries passed between the partisans.

Such duplication of effort was evidently quite wasteful, and under the initiative of Professor A. E. WHITE, of the University of Michigan, both bodies appointed a committee to consider whether consolidation could be effected. This joint conference, after finding the societies financially solvent, formulated a plan of amalgamation which has now been submitted to the membership and its adoption recommended by the national officers.

Briefly, the plan contemplates a society to be named "The American Society for Steel Treating," with headquarters in Cleveland, to assume the assets and liabilities of the two founder organizations. Membership qualifications and classification are practically unchanged, while the annual dues for members are to be fixed at $10, members of the founders' societies having their membership extended a time covered by the balance of their paid-in dues. Such members will vote on the proposed consolidation, and participate in the election of new general officers.

There seems to be very little to be said against such a move for the unification of effort among heat treaters, except perhaps the individual pride which enthusiasts feel in a pet project. Even this can be well expended in making a joint association better, bigger, and more worthwhile than either one of a sharply competing pair could be.

There certainly is a world of opportunity waiting the effort of any earnest body of men who start out to correlate the scientific principles of metallurgy to the everyday technique of heat treating. In such an aim the new society should and will enjoy the undivided support of all manufacturers, metallurgists and artisans who believe in making good steel better.

The Mission Of Sir Oliver Lodge

SIR OLIVER LODGE is lecturing to capacity audiences with standing room only and applicants turned away. He has been made the subject of no little criticism from sources distinguished for scientific learning and research on the ground that he reveals nothing in physics or chemistry, hitherto unknown. Why, it is asked, does a man of his standing and achievement address himself to the elements of physics and then meander off into the imaginary field of ghosts and spooks? As a man of science, why does he not appeal to scientific men and either prove his case or quit?

We are not in sympathy with these strictures, although a diligent reading of his books and earnest attention at a number of his lectures have failed to persuade us of his conclusions. But as men of science it behooves us above all things to maintain catholic minds. We may have some curious ideas of our own perchance that would not find general acclaim if they were told to the world. Sir OLIVER is one who in the ripeness of his years has suffered a great sorrow. His investigations into psychical research had already persuaded him that communication may be held with the spirits of the dead. It seems to us a strange and unprofitable notion, but it does not seem so to him, and he is a man of great intelligence as well as a keen observer. He is entitled to his own conclusions. And he has found such comfort and solace in them that he believes others may do likewise. This is the basis of his plea.

"Our faculties," he says, "have not been developed for purposes of philosophy," and since our principal occupation is the business of living, we do not consider the ether of space. He makes a strong plea, however, for the postulate of the ether of space, and holds that without it the conductivity of light is impossible. The observation that light is affected by gravity, and is accordingly a ponderable thing, leads to the conclusion that if the ether can maintain one ponderable thing it can also maintain many others. That we have no organs to apprehend such phenomena except light and Hertzian waves does not prevent the existence of a great variety of things that may be present with us in the ether, despite all our denials. His plea is that within this medium which is to us both dark and impalpable there may exist the mystic state we know as consciousness. How consciousness can exist without all the nitrogenous paraphernalia of nerve-stuff is beyond the understanding of the writer of these lines, but Sir OLIVER'S argument is that it cannot be definitely and conclusively denied; and that is true. We know very little of consciousness anyway. Starting with this, he builds up his structure of persuasion.

Well, why shouldn't he? Science is not a close cor-

poration and its literature is not included in an *index expurgatorius*. Men of science are individuals, and they are entitled to any opinions they please to hold. Life would be dull indeed had they to march like a company of Prussian infantrymen. We have our friend Dr. JACQUES LOEB of the Rockefeller Institute, who is the protagonist of the mechanistic theory of life, and now along comes Sir OLIVER with a theory of vitalism that beats the biologists in opposition. That is as it should be. It is said of Sir OLIVER that he is a delightful companion, and we know few men indeed who are more engaging in conversation than Dr. LOEB. Both are worthy of praise for their courage to speak. Let us keep our minds open, avoid censure, and hold our hearts ever young in the hope for more light.

Reversing the In and Out Ratio of the Chemical Engineers

ABOUT twelve years ago a small group of chemical engineers held a meeting in Philadelphia and organized a society which they called the American Institute of Chemical Engineers.

In the constitution of the society they stated the objects of the organization should be:

> To advance the cause of applied chemical science.
>
> To give the profession of chemical engineering such standing before the community as will justify its recognition by municipal, state and national authorities in public works.
>
> To raise the professional standard among chemical engineers, discouraging and prohibiting unprofessional conduct.
>
> To co-operate with educational institutions for the improvement of the education of the men who are to enter this profession.
>
> To encourage original work in chemical technology.
>
> To promote pleasant acquaintance and social and professional intercourse among its members.
>
> To publish and distribute such papers as shall add to classified knowledge in chemical engineering and shall increase industrial activity.

How well the society has succeeded in accomplishing these several purposes in their fullest measure is largely open to conjecture. In the first place the membership has been so limited by rules for qualification that there are six times as many eligible men out of the society as there are in it. The non-member engineer has felt content to stay among the "six outs," while hitherto the "one in," overcome with the honor of being "all qualified," has lost sight of the real broad purposes of the society in strengthening by uniting the chemical engineering profession and done nothing toward reversing the ratio of membership. However, it may confidently be stated that a new spirit has come into the Institute and that during the present year it is planned to start a campaign to make it as alive and representative as any of the other great American engineering societies.

To do this will not mean that high standards will of necessity be disregarded, but only that they will have to be adjusted to a practical degree. This matter will be left to the council of the society to decide on in the case of each individual application for membership nomination. As the society grows in numbers, the scope of its influence will increase. It will form a nucleus around which can be rallied the very old, widely scattered, most neglected and but recently appreciated profession of chemical engineering. The society will then take on more weight and be of a wider national importance.

What To Do With Five Million

IT IS a pleasure, indeed, to learn that the Carnegie Corporation of New York has announced its purpose to give $5,000,000 for the use of the National Academy of Sciences and the National Research Council. We take pleasure in adding our congratulations to these agencies on this deserved recognition.

The suggested plan to erect in Washington a suitable home for these organizations appeals to us as a scheme worthy of support, and we trust that this program can be carried through in the very near future. Washington is more and more coming to be recognized as a world center as well as a national center for things scientific and technical. It is the logical place for certain co-ordinating and directing agencies in this field. Our Federal Government activities there, the presence of many technical organizations and societies, and the less strenuous atmosphere of a community not so intimately associated wth industrial life, all favor clear thinking, research, and sound scientific development work.

This new recognition of Washington should augment greatly the scientific life of our national capital. Particularly we hope that this new building may be so arranged as to become the real scientific center of the city. In our opinion we should find gathered in this structure the headquarters of scientific and technical organizations which maintain Washington offices. We should find there the offices of our most prominent scientific workers of various sorts who are outside the Government, and we should hope that club facilities might also be associated with this structure, possibly even to the extent of a well-appointed structure housing one of the existing clubs such as the Cosmos Club. Anyone familiar with the great advantages in New York City of the United Engineering Societies Building and the adjoining Engineers' Club knows how splendid an opportunity it affords to technical men when this combination is properly worked out. We trust that these possibilities will be very carefully considered by the management of these agencies in Washington which have been so fortunately recognized, before the exact plans and program for their new home are formulated.

Creative Engineering And Theoretical Science

ECONOMICAL attainment, next to actual accomplishment, is the most essential requisite of engineering. Therefore the ability wisely to govern expenditures of money and materials must be possessed to a high degree by all responsible engineers. This does not mean that they should be penurious individuals, spectacled ledger column totalers or the like. They should, however, have a keen perception of the effect on their work of variations in costs with changes in design and be able to adjust their plans to approach as closely as possible the most satisfactory economic solution. In cases where many of the technical details have been established by actual performance, a mass of data compiled from practice is usually available as a guide, the proper use of which will enable any designer to locate what has previously been found faulty and make suitable amendments accordingly. Most engineering practice consists of adapting well established designs to new settings with a certain amount of fault eradication thrown in for novelty. Creative engineering, on the

other hand, must start with the formulation of an economic, scientific and technical program in combination, if the enterprise is to be assured any certainty of success.

In this issue there is offered to the reader the first of a serial of four numbers entitled "The Theoretical Study of Nitrogen Fixation by the Electric Arc." It affords an excellent example of the relation of theoretical science to creative engineering. It is to be hoped that Dr. STEINMETZ by publishing these articles is giving ideas that will shortly be converted to use not alone among those interested in nitrogen fixation by the arc, but by all investigators of problems having similar factors. At the same time, it is our thought that by reviewing such a study, any readers who are by nature not followers but leaders and developers of engineering will find pleasure in this opportunity to freshen as well as to maintain their acquaintance with the astute art involved in it.

It is to be regretted that the vast majority of our technical school and college graduates regard integral and differential calculus as a sort of mental gymnastics, which upon graduation is to be abandoned along with football, baseball and other forms of vigorous effort. Many an intending reader will find himself to be a member of this majority, and if he believes he would like to become better acquainted with the ways of our eminent contributor, he would do well to provide himself with the mathematical text books the same author has written specially for engineers and get busy! The tonic effect on his mental life would be prodigious.

New York Public Library Combines Science With Technology

THE great New York Public Library on Fifth Avenue extending from Fortieth to Forty-second Street is pretty well in the heart of things. It is not set back in an academic retreat, under shady trees, inviting only scholars to enter and browse. It is visited every day by thousands of people—from 8,000 to 10,000 in fact—and most of these visitors come with a purpose. They want to know something—and usually they want to know it right away. It is a vast storehouse of books, millions of books, periodicals, pamphlets, prints and the like, and substantially everything it contains is available on demand.

Now, leaving out medicine and biology, zoölogy and botany, which are housed in other departments, the works relating to science were divided into two sections: pure and applied, or rather, as they called it, Science and Technology. Practice shows what in all modesty we have been trying for years to preach: that science and technology may not be separated. And because they constantly overlap, the sections have been consolidated. The library authorities have long felt the need of this arrangement, and now it is practically an accomplished fact. In chemistry, for example, all material relating to the subject has been brought into one large room, whether it be in regard to pressing oil from copra or to determining atomic weights.

Of course difficulties will always present themselves, and one such had to do with the problem of treating works on electricity and on electric processes—excepting electrochemistry. These have been consolidated, under the general heading of Technology. Of course all study of electricity is not technological, but the point is they shift so fast from pure science to technology that these must be kept together. For instance, the measurement of electricity was formerly a problem of pure science, whereas now it is distinctly a technological matter.

Still another difficulty was the separation of books and periodicals relating to mining and metallurgy, on the one hand, from those on geology, on the other. They were found to interlock so closely that they were brought together in the Science room. According to the general definitions, mining and metallurgy are both technological subjects, while geology, although it is as practical and as often applied as psychology, still ranks as "pure" science. The relationships, however, of the three professions are such as to make it necessary to keep them together. In short, the titles of the three divisions of Science, Technology and Chemistry are merely names. Chemistry, with approximately 10,000 volumes, is so big that it has to be housed by itself, while Science and Technology are but traditional designations that indicate the necessary separation of a department of science into fractions of the whole that would otherwise become cumbersome on account of its size. All these divisions are completely catalogued.

The relation between physics and engineering (with the exception of the field of chemical engineering, which is included in chemistry) is not close enough for the two to be consolidated, so that mathematics and pure physics still remain in the general category of Science, while all general engineering works are included in Technology. Such subjects as Military Science and Art, Agriculture, etc., are so placed as to be in stacks convenient to the section of Technology. Indeed all of these Science sections are contiguous to one another.

Scientific periodicals to the extent of about 600 titles are shelved, and index cards are made of contents, both as to subject and author. This indexing is carried out by a system whereby the current number of each periodical is not kept away from its place for over 24 hours, and check cards provide for the prompt return of numbers in use. Generally current periodicals are checked up and indexed within one week after receipt. Check cards are also kept of all books ordered.

We cannot urge too strongly upon manufacturers whose works are under scientific control the need of a proper administration of their scientific libraries. Books are useless things unless their contents are available, and neither titles nor names of authors are adequate to point to the information that is sought and frequently furnished with all the authority and accuracy of careful compilation and printing. A library is not a rest room or a sleeping apartment, neither is it properly a conference room, although we have seen a number of technological libraries that seem to be so regarded. The management of the New York Public Library is famous for its efficiency, and Mr. GAMBLE, who has charge of the general departments of Science, Chemistry and Technology, and his assistants are always both willing and disposed to give aid to those seeking information as to good library administration.

There are people not interested in libraries; their mental horizon is bounded by what man can remember. And yet it was Professor FRIEDEL of Paris who took one of his assistants by the arm and, pointing to his books, said, "Voila, mon ami! There is all I know. Books are useful instruments, and we should use them. Why should I clog my brains with a multiplicity of detail which is all set forth and easily obtained from their printed pages? But the *general principles*, my friend, these I must ever keep alive in my mind!"

Western Chemical and Metallurgical Field

Victorville Cement Mill

THE application of electric drive in the operation of a cement mill and the advantages to be derived therefrom are unusually well exemplified in the plant of the Southwestern Portland Cement Co. at Victorville, California. The town is in the southwestern part of California, about 100 miles from Los Angeles, on the Santa Fe Railroad, the tracks of which pass by the plant, affording a convenient outlet for the finished product.

The mill has an output of 300,000 bbl. a year of portland cement, and employs approximately 80 people. All of the buildings are of substantial concrete construction, built to withstand the severe conditions imposed by the heavy cement mill machinery installed.

The system of manufacture used is known as the wet process, and water for use throughout the mill is raised to a reservoir on a hill back of the plant by a 15-hp. motor-driven triplex pump.

Rock and shale are brought to the mill from the quarry, which is located seven miles distant, by steam locomotive hauling trains of cars which have two compartments or hoppers, one of which is dumped at a time to the crusher.

Electric current is purchased from the Southern Sierras Power Co., thus relieving the company of the expense and trouble incident to the operation of a power plant. Current is received at 33,000 volts and stepped down to 440 volts, for application to the various motors installed throughout the mill.

The transformers and switching apparatus are of the outdoor type, located immediately adjacent to the mill. The current is taken from here to a seven-panel marble switchboard, from which it is distributed to the various power and lighting circuits in the mill.

The lime rock is delivered from the hopper cars direct to the crusher, but a reserve pile of crushed stone, amounting to between 3000 and 5000 tons, is maintained, sufficient to keep the mill operating for a period of approximately 30 days. This reserve is maintained in the event of an accident, such as a washout, crippling the railroad service from the quarry to the mill.

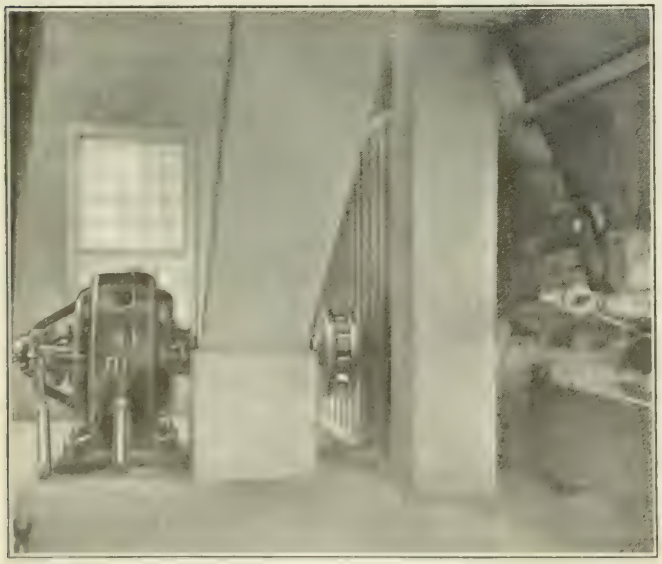

FIG. 1. 250-HP., 60-CYCLE, 700-R.P.M., 440-VOLT WESTINGHOUSE TYPE CW MOTOR DRIVING CRUSHER AND WILLIAMS MILL.

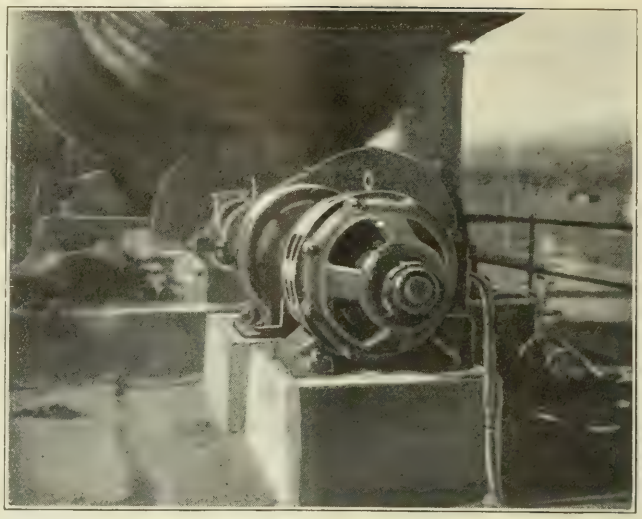

FIG. 2. 50-HP., 440-VOLT, 60-CYCLE, 3-PHASE, 700-R.P.M., MOTOR DRIVING ROTARY KILN

The crusher and Williams mill are driven by a 250-hp. Westinghouse type "CW" wound motor as is shown in Fig. 1, which breaks the rock into pieces about the side of a walnut or a little larger. From here the rock is elevated to a storage bin by a bucket elevator, driven by a 30-hp. motor, and thence by belt conveyor to the pulverizing house. Up to this time no water has been put with the rock except what is thrown on at the time it goes into the crusher, which is done with a hose to eliminate whatever dust rises at that time.

During the process of pulverization, water is added, eliminating the dust. After being thoroughly pulverized the mixture is taken to the slurry tanks, where it is kept in motion by air agitation until ready for admission to the kiln.

There are six slurry tanks, served in pairs by elevators operating at a speed of approximately 88 ft. per min., for elevating the mixture from the pulverizing house tanks. These elevators are driven by a 7½-hp. constant speed motor.

After the mixture has been thoroughly agitated it is transferred to the slurry tanks nearest the kiln. From here it flows into a sump and is delivered to the kiln by a motor-operated measuring device. The dipper is made in the shape of an "S," the outlet being in the center. By raising and lowering the dipper in the sump the amount of slurry entering the kiln can be controlled. The dipper is driven by an extended shaft, provided with two universal joints, from one of the elevators and is raised and lowered by a ¼-hp. 1725-r.p.m. motor by means of remote control from the clinker end of the kiln. A large indicator is visible to the operator at the clinker end, and he can feed the proper amount of mixture to the kiln, and control the temperature of his fire at the same time.

Fig. 3, taken from CHEMICAL & METALLURGICAL ENGINEERING, vol. 19, p. 440, shows the general layout of the kiln building, slurry tanks and burner equipment. The rotary kiln is approximately 200 ft. long and 20 ft. in diameter, lined with firebrick and heated by an oil burner to a temperature of about 2500 deg., which is measured by a radiation pyrometer. It is driven at a speed of one revolution per minute by a 50-hp. type "CW" 700-r.p.m. motor through Foote reduction gears

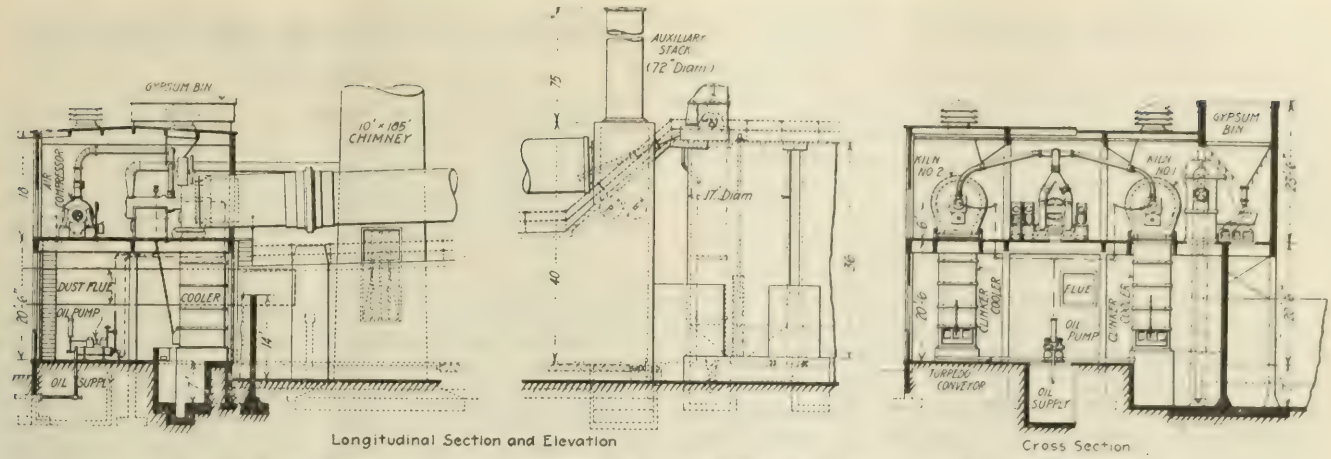

FIG. 3. LAYOUT OF KILN BUILDING, SLURRY TANKS AND BURNER EQUIPMENT

(Fig. 2). Upon coming from the kiln the clinker falls about 20 ft. into a pit to allow it to cool somewhat; it is then elevated by the clinker elevator, which is driven by the 7½-hp. 680-r.p.m. motor shown in Fig. 4 to an automatic scale and dumped into the storage bin. From the clinker storage it is transferred by means of locomotive crane with a clamshell bucket to a bin from which it is fed into a finish mill. The locomotive crane is also used for mixing the clinker, as it will vary somewhat in quality. After being ground and analyzed by the chemical laboratory, it is ready for the packing house, to which it is carried on a belt conveyor over a weighing machine, which automatically records the number of barrels that pass.

From the storage bins, the cement is taken to the sacking machines, driven by a 15-hp. motor. A sack cleaner is driven by a 7½-hp. 680-r.p.m. motor through a Foote reduction gear. A 15-hp. motor-driven blower for collecting dust from the sacking and sack cleaning machines is also used.

All motors are of Westinghouse design, alternating current, 440-volt, 60-cycle, three-phase. This plant was designed and built by Mr. L. D. Gilbert, and has been in operation over three years, during which time no shutdowns have been experienced due to any trouble with the electrical equipment. It is a model plant from every standpoint, extremely well built and practically dustless.

It is not only an excellent plant from a mechanical standpoint and an efficient producer of high grade cement, but is notable to chemists as being the location of extensive experiments on the wet-cleaning of kiln gases for the recovery of potash. This phase of their work has already been exhaustively described by their chemical engineer, J. A. Dean, in CHEMICAL & METALLURGICAL ENGINEERING for Sept. 26, 1918, vol. 19, p. 439.

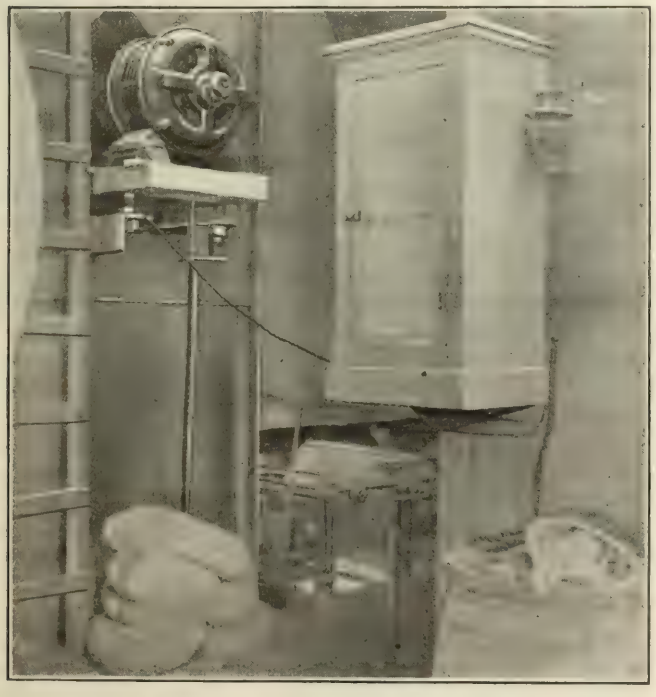

FIG. 4. 7½-HP., 680-R.P.M., 440-VOLT, 60-CYCLE, MOTOR DRIVING CLINKER ELEVATOR

Radium Minerals

Radium minerals are generally found in connection with granitic masses—that is, in places where granite forms at least part of the rock of the country. Most of the original radium minerals, such as uraninite, samarskite and brannerite, are black and have a shiny fracture and a high specific gravity. These minerals are rarely found in commercially valuable quantities. Pitchblende, which has the same composition as uraninite and the same general appearance except that it shows no crystal form, occurs in veins. It has been found in only a few places—in Bohemia, southern Saxony, Cornwall, and Gilpin County, Col. When these original minerals break down through weathering, other radium minerals are formed from them, such as autunite, torbernite, carnotite, and tyuyamunite.

Carnotite and tyuyamunite are the most abundant of these minerals and now furnish the bulk of the world's radium. They cannot be told apart by the eye, for both are of bright canary-yellow color and are powery, finely crystalline, or, rarely, claylike in texture. Carnotite is a hydrous potassium-uranium vanadate. Tyuyamunite is similar in composition but contains lime instead of potash. The greatest known deposits of these two minerals are in southwestern Colorado and southeastern Utah, where both are associated with fossil wood and other vegetation in friable, porous, fine-grained sandstone. Small quantities of carnotite have been produced near Olary, South Australia. The only other deposits that yield tyuyamunite in notable quantity are those of Tyua-Muyun, in the Andiyan district, Ferghana Government, central Asiatic Russia (Russian Turkestan), where tyuyamunite occurs with rich copper ores in a pipe in limestone.

Dye Bill Ready for Senate

THE Senate Committee on Finance has finished its consideration of the coal-tar products bill. The form in which the bill will be reported to the Senate differs materially from the third sub-committee draft, which was discussed in CHEMICAL & METALLURGICAL ENGINEERING, Feb. 11, 1920, p. 248.

REDUCTION IN TARIFF RATES

The most striking change is the reduction in the traiff rates, the rate for commodities in Group II (intermediates) having been changed from 40 to 15 per cent *ad valorem*. Finished products, Group III, were reduced from 45 to 30 per cent *ad valorem*. The special duties of 6c. per lb. for articles in Group II and 7c. per lb. for Group III have been changed to 2½c. and 5c., respectively. The latter figure also serves as a basis for computing the duties on dyestuffs which exceed the standards of strength which shall be established by the Secretary of the Treasury.

On and after the date of passage of the act, no package containing dyestuffs shall be admitted if it or the invoice bears any false or misleading statement as to the nature of the contents.

CHANGES IN DUTIABLE LIST

With the exception of natural methyl salicylate or oil of wintergreen or oil of sweet birch, and natural coumarin, the natural products mentioned in our last issue as having been removed from Group III have been retained in that group.

SUPERVISION OF IMPORTS LIMITED TO THREE YEARS

Section 504 now provides that the Tariff Commission shall regulate the importation of coal-tar products for three years.

PRACTICE AND PROCEDURE

Section 508 has been modified in accordance with Mr. Choate's suggestions and now reads as follows:

> Sec. 508. That the United States Tariff Commission, in executing the duties imposed upon it by this act, may regulate its own practice and procedure and make all rules and regulations necessary and proper for the accomplishment of the purposes of this act: Provided, That no article enumerated in Group II or Group III of section 500 of this act shall be admitted to entry or delivered from customs custody in the United States or in any of its possessions in any case where the United States Tariff Commission shall determine that the actual consumer for whose use such article is intended has received or may obtain on reasonable terms as to quality, price, and delivery, a six months' supply of such article: And provided further, That no article enumerated in Group II or Group III of section 500 of this act which may be useful both as a substitute for a domestic article and for some other purpose for which the domestic article is not adapted shall be admitted to entry or delivered from customs custody in the United States or in any of its possessions, except when the United States Tariff Commission shall determine that such article is imported for such other purpose.

PURPOSE OF THE ACT

The concluding section of the bill states: "That it is hereby expressly declared to be the intent of the Congress in enacting this act to build up, develop and protect the dyestuffs manufacturing industry in the United States and its possessions, and that each and every of the foregoing sections shall be so construed as to effectuate such intent."

American Engineering Standards Committee

AFTER almost three years of painstaking investigation and discussion by the engineering fraternity, and under the able guidance of Prof. Comfort A. Adams as chairman, the revised constitution of the American Engineering Standards Committee, along with the by-laws and rules of procedure, has been adopted, and has been ratified by the American Society of Civil Engineers, the American Institute of Mining & Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials, and the three Government Departments, Commerce, Navy and War. Each of these interests have three representatives, and although the Committee as it exists today consists of twenty-four members, the new Committee is of very wide scope and allows the direct or indirect participation of anyone interested in standardization.

A. A. Stevenson is the newly elected chairman and Dr. P. G. Agnew is now permanent secretary, with headquarters at the Engineering Societies Building, 29 West 39th St., New York City.

OBJECTS

The American Engineering Standards Committee makes it possible to give an international status to approved American engineering standards and to co-operate with similar organizations in other countries. Similar organizations are now functioning in Great Britain, France, Switzerland, Holland and Canada.

Through the new Committee the methods of arriving at engineering standards will be unified and simplified and, by co-operation, the duplication of standardization work will be prevented. Standards will not be created without giving all interested an opportunity to participate.

The American Engineering Standards Committee is not only ready for business but it has made considerable practical headway, and now that the organization of the Committee has assumed such definite and precise form, no doubt its activities will be greatly extended and accelerated.

HOW THE COMMITTEE OPERATES

Any organization may request the Committee to approve standards which it has formulated, or to approve committees that it has appointed, and by so doing becomes a sponsor society.

A standard must be referred to as that of the sponsor, using whatever title the sponsor has given it, followed by the statement: "Approved by the American Engineering Standards Committee." The approval may be given in one of three ways: "Recommended Practice," "Tentative Standard" or "American Standard."

Any standard or group of standards adopted by any organization or in process of preparation, prior to Jan. 1, 1920, may be approved by the Committee, if in the opinion of the Committee it has either been developed by a properly constituted committee, or has, by actual practice, proved its right to become a standard.

The Committee will also act as a bureau of information regarding standardization. It will collect information regarding existing standards and as to the bodies that have formulated or adopted them. This will enable it to properly give the data to those who

select a committee to formulate a new standard or revise an old one.

Provision is made for direct representation on the American Engineering Standards Committee, of additional organizations (or groups of organizations) interested in engineering standardization. Already several important additional organizations of national standing have applied for membership on the Committee.

Bureau of Mines Will Investigate Tunnel Ventilation Problems

A NUMBER of inquiries have come to the Bureau of Mines in regard to the ventilation problems arising in the construction of tunnels to be used principally by motor vehicles. It is a well-known fact that the exhaust gases from such vehicles contain varying proportions of poisonous gases, especially carbon monoxide, which has caused many cases of asphyxiation in closed garages where automobile motors have been permitted to run. It is evident, therefore, that the construction of a long tunnel such as is now being designed for automobiles under the Hudson River between New York and New Jersey presents an unprecedented problem in providing adequate ventilation to render these gases harmless.

This particular tunnel will be 8,000 ft. long, and it is estimated that 2,113 motor vehicles may pass through it in one hour. The amount of gases that will be generated by these machines will be extremely large, and there are no data available on which the exact amount can be computed, because the percentage of carbon monoxide in the exhaust from gasoline engines varies with the condition of use, the load carried, the adjustment of the carburetor and other factors. The proportion of carbon monoxide can, therefore, not be determined theoretically, and the only way to arrive at figures which may be used for a basis for ventilation designs is to make a large number of tests with various types of automobiles under the different conditions to which their use in the tunnel will be subjected.

Physiological Investigations Necessary

Another important phase of this ventilation problem is the proper amount of dilution to render these exhaust gases harmless. Physiological authorities differ on the percentage of carbon monoxide that a human being may breathe without suffering any injury. Most of the information now available has to do with the effect of small percentages of carbon monoxide on miners and other workmen. Little if any consideration has been given to the effect of this gas and other constituents of exhaust gases on persons in delicate health, or to their effect on women and children. Physiological investigations should, therefore, be made from this point of view to provide information from which a figure can be determined for the proper dilution of these poisonous gases.

It is evident that the engineering design of the tunnel and arrangements for removing the deleterious or toxic gases, and the kind of ventilating apparatus, must be correlated to the quantity of production of such gases and the physiological test results.

Other Hazards in Tunnel Construction

From past experiences in driving tunnels under the Great Lakes and elsewhere, as at Milwaukee and Cleveland, it has been found that inflammable gases have been encountered and caused in one instance a disastrous explosion, killing twenty men and injuring thirteen. Other similar tunnels for water supply are now being planned. There is need of investigating the conditions in which such gases are encountered, safe methods of elimination, and protection from ignition by electric power or other causes, and the best methods of ventilation as affected by the design of the tunnel and the appliances used.

The Bureau has been called upon by certain state commissions to determine the safety and construction of certain tunnels in quicksand or water-bearing ground, the methods of bulkheading and the need of putting in air locks to prevent inrushes, and, where such bulkheads and airlocks were used, of methods of ventilation to provide for the carrying away of inflammable and deleterious gases.

There is also a need for investigating diseases of workmen caused by the presence of other deleterious gases than carbon monoxide, or by high air pressure in tunnels and shafts under water pressure, or in sinking caissons for bridge piers and buildings, especially the caisson disease, which is attributed to high air pressure. It is expected that with a better knowledge of these diseases and their causes, means of lessening or preventing them can be developed by adoption of proper methods and appliances.

Tunnels Under Consideration

The Hudson River vehicular tunnel has been mentioned because the construction work on this tunnel is to be started soon, and there is an urgent need for information on which the ventilation design may be based. There are, however, a number of other tunnel projects in various parts of the United States, among them being a vehicular tunnel through the South Hills at Pittsburgh, Pa., which will be 6,000 ft. long. Tunnel designs are also under consideration in Boston, Mass., San Francisco, Cal., and New Orleans, La. Furthermore, the time is rapidly approaching when heavy motor truck traffic will pass under the streets of large cities; such a project is now being considered for Chicago. A system for avoiding pollution of the atmosphere in such subways is urgently needed.

From the foregoing, it will appear that the problem is one of national importance, and investigative work should be commenced immediately in order that definite information may be provided on which recommendations can be made to Federal, state and municipal officials regarding methods of ventilation, physiological effects of various tunnel gases, absorbents and protective appliances for such gases, and engineering designs, in order that the atmosphere in such tunnels, shafts and other places may be made safe and healthful, not only during the construction period, but for all time, and danger from fire and explosions may be reduced to a minimum. Accordingly, it is recommended that Congress be requested to make an appropriation of $100,000 for the purpose of undertaking the work.

The immediate need for such data is further emphasized by the fact that the report of the New York commission which is studying the Hudson River vehicular tunnel has been submitted to the Governor and the Legislature. The preliminary work will probably be started about Sept. 1. The report of Chief Engineer C. M. Holland refers to the progress of the investigations being carried out under contract by the Bureau of Mines.

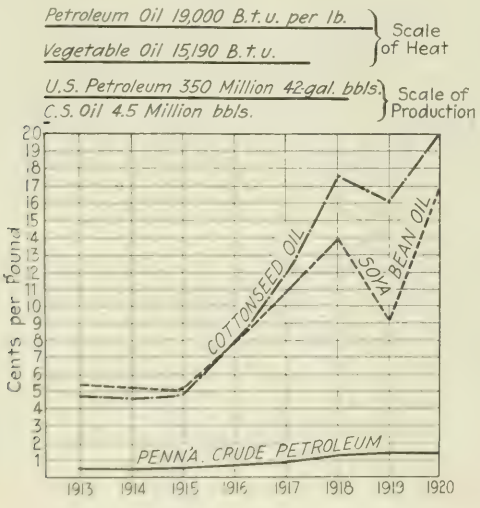
Chemical Societies Discuss Liquid Fuels

ON FRIDAY evening, Feb. 6, the New York Sections of the A. E. S., A. C. S. and S. C. I. held a joint meeting at Rumford Hall. The subject of liquid fuel was discussed. Sumner R. Church of The Barrett Co. opened the program by reviewing the various aspects of the use of coal tar for fuel. He said that some tar was being burned in open-hearth steel furnaces, especially in plants having byproduct coke oven tar available. This practice was started during the war-time fuel shortage. The sulphur content in these tars has been found to average about 0.38 per cent and they are therefore highly satisfactory for use where low-sulphur steel is required. Metallurgical coke containing less than 0.3 per cent ash, 1.0 per cent volatile and 0.11 per cent sulphur is now being made by retorting hard pitch. This coke can be used in the manufacture of high-grade electrodes. Of the tar oils, 90 per cent benzol is an important fuel, being used in making high-grade blended gasolines. As benzol freezes at 32 deg. F., it does not lend itself well for motor fuel use in the pure state. However, more than can be produced is in demand for increasing the vapor pressure of the lower cut gasolenes. Dead oil was used by the British Navy for fuel during the war. In this country it has been burned extensively for the manufacture of lampblack, but the great demand for creosotes for railroad tie, paving block and other wood preservation has made the supply of oils derived from the tar acid fractions limited.

Vegetable Oils

Dr. David Wesson next spoke on the fuel possibilities of vegetable oils. He gave comparisons between petroleum and seed oils, as follows:

The thermal values of petroleum oil and vegetable oil, the relative production of the two oils, and also the prices of cottonseed and soya bean oils for the last seven years, in comparison with the price of crude



Petroleum Oil 19,000 B.t.u. per lb.
Vegetable Oil 15,190 B.t.u.
Scale of Heat
U.S. Petroleum 350 Million 42-gal. bbls.
C.S. Oil 4.5 Million bbls.
Scale of Production
Cents per Pound
